# TRACTABILITY OF THE FREDHOLM PROBLEM OF THE SECOND KIND 

A.G. WERSCHULZ AND H. WOŹNIAKOWSKI<br>Communicated by Ian Sloan

$$
\begin{aligned}
& \text { ABSTRACT. We study the tractability of computing } \varepsilon \text { - } \\
& \text { approximations of the Fredholm problem of the second kind: } \\
& \text { given } f \in F_{d} \text { and } q \in Q_{2 d} \text {, find } u \in L_{2}\left(I^{d}\right) \text { satisfying } \\
& u(x)-\int_{I^{d}} q(x, y) u(y) d y=f(x) \text { for all } x \in I^{d}=[0,1]^{d} .
\end{aligned}
$$

Here, $F_{d}$ and $Q_{2 d}$ are spaces of $d$-variate right hand functions and $2 d$-variate kernels that are continuously embedded in $L_{2}\left(I^{d}\right)$ and $L_{2}\left(I^{2 d}\right)$, respectively. We consider the worst case setting, measuring the approximation error for the solution $u$ in the $L_{2}\left(I^{d}\right)$-sense. We say that a problem is tractable if the minimal number of information operations of $f$ and $q$ needed to obtain an $\varepsilon$-approximation is sub-exponential in $\varepsilon^{-1}$ and $d$. One information operation corresponds to the evaluation of one linear functional or one function value. The lack of sub-exponential behavior may be defined in various ways, and so we have various kinds of tractability. In particular, the problem is strongly polynomially tractable if the minimal number of information operations is bounded by a polynomial in $\varepsilon^{-1}$ for all $d$.

We show that tractability (of any kind whatsoever) for the Fredholm problem is equivalent to tractability of the $L_{2}$ approximation problems over the spaces of right-hand sides and kernel functions. So (for example) if both of these approximation problems are strongly polynomially tractable, so is the Fredholm problem. In general, the upper bound provided by this proof is essentially non-constructive, since it involves an interpolatory algorithm that exactly solves the Fredholm problem (albeit for finite-rank approximations of $f$ and $q$ ). However, if linear functionals are permissible and $F_{d}$ and $Q_{2 d}$ are weighted tensor product spaces, we are able to

[^0]surmount this obstacle; that is, we provide a fully-constructive algorithm that provides an approximation with nearly-optimal cost, i.e., one whose cost is within a factor $\ln \varepsilon^{-1}$ of being optimal.

1. Introduction. The Fredholm problem of the second kind consists of finding a $d$-variate function $u$ such that

$$
\begin{equation*}
u(x)-\int_{I^{d}} q(x, y) u(y) d y=f(x) \quad \text { for all } x \in I^{d}=[0,1]^{d} \tag{1}
\end{equation*}
$$

Here, $f \in F_{d}$ and $q \in Q_{2 d}$, where $F_{d}$ and $Q_{2 d}$ are given classes of functions that are respectively defined over $I^{d}$ and $I^{2 d}$. We want to determine the complexity of computing the solution of (1) to within $\varepsilon$ in the worst case setting. This means that we want to find an algorithm that solves this problem with minimal cost. Here, we measure cost by a weighted sum of the total number of function values or linear functionals of the specific right hand function and the kernel, and the total number of arithmetic operations.

The first paper on the complexity of the Fredholm problem of the second kind was already published by Emelyanov and Ilin [4] in 1967. The problem was to approximate the solution with right hand functions and kernels being $r$-times continuously differentiable. Their result was that the minimal worst case error of algorithms that use at most $n$ function values is proportional to $n^{-r /(2 d)}$. This means that the complexity of computing an $\varepsilon$-approximation is proportional to $\varepsilon^{-2 d / r}$, with the proportionality factor depending upon $r$ and $d$. After a quarter-century hiatus, researchers in information-based complexity began looking once again at the complexity of this problem. A partial list of results includes Azizov [1], Dick, et al. [3], Frank, et al. [5], Heinrich [7], Heinrich and Mathé [8], Pereverzev [15] and [12, 19, 20, 21]). Results were also obtained for the solution at a point as well as for a global solution and for various Sobolev spaces in the worst case and randomized settings.

The papers $[\mathbf{5}, \mathbf{1 5}, \mathbf{2 0}, \mathbf{2 1}]$ treated the worst case setting for Sobolev spaces, see also [19]. They found the complexity to be proportional to $(1 / \varepsilon)^{d \alpha}$, with a positive $\alpha$ dependent upon the smoothness parameters of the spaces but independent of $d$. Again, the proportionality factors depend upon $d$ and the smoothness parameters. Typically, it
is not known if dependence upon $d$ is exponential or maybe "only" polynomial.

These results are fine when $d$ is so small that computing exponentiallymany (in $d$ ) information or arithmetic operations doesn't faze us; so for many problems in science and engineering, in which we have $d \leq 3$, these results are computationally relevant. But what happens when $d$ is so large that we can no longer afford to calculate (say) $2^{d}$ function values or linear functionals or arithmetic operations? When this happens, we are stymied by the exponential (in $d$ ) behavior of the $\varepsilon$ complexity for the $d$-dimensional problem, which Bellman [2] called the "curse of dimensionality." In fact, there are many multivariate problems for which the curse of dimensionality is indeed present. Since we are dealing with complexity (minimal cost), there's no way that we can find a cleverer algorithm for the problem. If we really want to solve the problem, we have two choices:

1. We can weaken the assurance given by the worst case setting, typical choices being the average case, probabilistic, or randomized settings.
2. We can stay with the worst case setting, but reformulate the problem using different spaces for $F_{d}$ and $Q_{2 d}$.

The papers by Heinrich [7] and by Heinrich and Mathé [8] pursued the first choice, using the randomized setting. For the second choice, we usually ${ }^{1}$ shrink the original spaces $F_{d}$ and $Q_{2 d}$ by introducing "weights" that measure the importance of successive variables and groups of variables. Dick et al. [3] pursued this latter path, a choice we also follow in this paper.

Vanquishing the curse of dimensionality for multivariate problems forms the heart of research into tractability studies. A problem is tractable if the information complexity is sub-exponential in $\varepsilon^{-1}$ and $d$. Information complexity is defined as the minimal number of information operations needed to compute an $\varepsilon$-approximation, with one information operation being understood as the evaluation of one function value or one linear functional. If we specify a particular non-exponential behavior, we get a specific kind of tractability. For example, polynomial tractability means that non-negative $C, p$ and $q$ exist such that the information complexity is bounded by $C \varepsilon^{-p} d^{q}$ for all $\varepsilon \in(0,1)$ and all $d=1,2, \ldots$. If $q=0$, then we have strong polynomial tractability.

This is an especially challenging property since then the information complexity has a bound independent of $d$. It is good to know that strong polynomial tractability holds for many multivariate problems with properly decaying weights.

Obviously, the information complexity is a lower bound on the (total) complexity. Therefore, the complexity is sub-exponential in $\varepsilon^{-1}$ and $d$ only if the problem is tractable. If the complexity is more or less the same as the information complexity, then the study of complexity and tractability coincide. The last assumption means that the total number of arithmetic operations needed to compute an $\varepsilon$-approximation is almost the same as the number of information operations. Interestingly enough, the last assumption holds for most linear problems and selected nonlinear problems. The current state of the art of tractability studies may be found in $[10,12,13]$.

Since the Fredholm problem is not linear, it is not clear a priori whether its total complexity is essentially the same as its information complexity. Dick et al. [3] showed that these were essentially (i.e., to within a logarithmic factor) equal for the problem that they studied; we show that this is also the case for the problem studied in this paper, provided that linear functionals are permissible and that $F_{d}$ and $Q_{2 d}$ are tensor product spaces.

Dick et al. [3] were the first to address the tractability of the Fredholm problem of the second kind. They considered $d$-variate right hand functions and $d$-variate convolution kernels from the same space, a weighted Korobov space with product weights. They obtained a result that is within a logarithmic factor of being optimal, and proved strong polynomial and polynomial tractability under natural assumptions on the decay of product weights. The algorithm for which this holds is the lattice-Nyström method, which uses function values; the resulting $n \times n$ linear system has a special structure, allowing it to be solved in $\mathscr{O}(n \ln n)$ arithmetic operations. Tractability of the Fredholm problem of the second kind is also addressed in [12, subsection 18.2].

In this paper, we study the Fredholm problem for kernel functions that may fully depend upon all $2 d$ variables. Moreover, we allow the spaces $F_{d}$ and $Q_{2 d}$ to be independent of each other, up to the final section of this paper, in which we will need to impose some relations between these two spaces by assuming that they are certain tensor
product spaces. That is, $F_{d}$ is the $d$-fold and $Q_{2 d}$ is the $2 d$-fold product space of some spaces of univariate functions.

The Fredholm problem is similar to the quasi-linear problems studied in $[\mathbf{2 2}, \mathbf{2 3}]$. The main difference is that the function spaces defining the linear and nonlinear parts of the problems studied in $[\mathbf{2 2}, \mathbf{2 3}]$ are both defined over $I^{d}$, whereas for the Fredholm problem these spaces are respectively defined over $I^{d}$ and $I^{2 d}$, and in general are not related. Moreover, papers $[\mathbf{2 2}, \mathbf{2 3}]$ only provided upper bounds on the complexity, and here we provide both upper and lower bounds.

We present two results in this paper. The first result exhibits relationships between the tractability of the Fredholm problem and the tractability of approximating the right-hand side and kernel function appearing in this Fredholm problem. Suppose that $F=\left\{F_{d}\right\}_{d=1,2, \ldots}$ and $Q=\left\{Q_{d}\right\}_{d=1,2, \ldots}$ are families of right hand sides and kernel functions for this problem. Under certain mild conditions on $F$ and $Q$, we show that

$$
\begin{equation*}
\operatorname{tract}_{\mathrm{FRED}} \equiv \operatorname{tract}_{\mathrm{APP}_{F}} \quad \text { and } \quad \operatorname{tract}_{\mathrm{APP}_{Q}} \tag{2}
\end{equation*}
$$

that is, tractability of the Fredholm problem is equivalent to tractability of the approximation problems for $F$ and $Q$. We stress that this holds for all kinds of tractability. This result is useful since the tractability of approximation has been studied for many spaces and much is known about this problem, see again $[\mathbf{1 0}, \mathbf{1 2}, 13]$. Since we have the equivalence (2), all these known tractability results can now be applied to the Fredholm problem.

The lower tractability bounds for the Fredholm problem are obtained by first taking a special $f$ or $q$ and then showing that the Fredholm problem is equivalent to the approximation problem for functions $q$ or $f$, respectively. We get the results in this paper by choosing the special functions $f=1$ and $q=0$.

The upper tractability bounds for the Fredholm problem are obtained by using an interpolatory algorithm that gives the exact solution of the Fredholm problem (1) with $f$ and $q$ replaced by their approximations. In general, this kind of algorithm will be impossible to implement. It does not matter for negative tractability results since, as we already mentioned, the total complexity is lower bounded by the information complexity. On the other hand, positive tractability results are in ques-
tion since it may theoretically happen that the information complexity is reasonable but the implementation cost may be too large.

So, for our second result, we address the problem of how to actually implement a good algorithm for the Fredholm problem. Suppose that linear functionals can be used, and that $F_{d}$ and $Q_{2 d}$ are weighted tensor product function spaces. In this case, we develop a modified interpolatory algorithm whose total cost is roughly the same as the information complexity. More precisely, we exhibit a fixed-point iteration that produces an approximation having the same error as the interpolatory algorithm, with a penalty that is at worst a multiple of $\ln \varepsilon^{-1}$. This proves that the complexity and the information complexity are essentially the same for tensor-product spaces, as long as linear functionals can be used.

We briefly comment on the case when only function values can be used. Using the results that relate the power of function values and linear functionals, see $[\mathbf{9}, \mathbf{1 7}]$, it is possible to show that in many cases polynomial or strong polynomial tractability is preserved. However, the tractability and complexity exponents may increase when function values are used. We omit the details of this study, so as to not make our paper even longer than it already is.

We now give a brief overview of the paper. In Section 2, we define basic concepts, such as the problem to be solved and various kinds of tractability for the problem. In Section 3, we show relations between tractability of the Fredholm problem and tractability of the $L_{2}$-approximation problems over the spaces $F_{d}$ and $Q_{d}$. In Section 4, we apply the results of Section 3. We first show that if either $F_{d}$ or $Q_{d}$ is a space of infinitely differentiable functions with the same role of all variables and groups of variables, then the Fredholm problem suffers from the curse of dimensionality. This means that even sufficiently high smoothness of functions does not imply tractability. Next, we look at the case where $F_{d}$ and $Q_{2 d}$ are general unweighted tensor product spaces, finding both positive and negative tractability results. Then we examine the case of weighted Sobolev spaces, once again getting both positive and negative results. Since introducing weights into Sobolev spaces can sometimes help us to vanquish the curse of dimensionality, we ask whether weights will do likewise for tensor product spaces. We define such weighted tensor product spaces in Section 5; ironically enough, weighted Sobolev spaces are not weighted
tensor product spaces, despite the fact that the positive results attained for weighted Sobolev spaces are what led us to consider weighted tensor product spaces in the first place. Finally, in Section 6 we suppose that continuous linear functionals are permissible and that the $F_{d}$ and $Q_{2 d}$ are weighted tensor product spaces (as in Section 5). We then exhibit a modified interpolatory algorithm, studying its implementation cost and showing that the total cost of this algorithm is nearly (i.e., to within a logarithmic factor) the same as the information complexity, so that this method is nearly optimal. It is worth pointing out that our proof of this result depends upon the weighted tensor product structure of these spaces, and hence it does not directly apply to weighted Sobolev spaces. However, it is also possible to prove this result for weighted Sobolev spaces; we omit a full discussion and proof, for the sake of brevity.
2. Basic concepts. Recall that $I=[0,1]$ is the unit interval ${ }^{2}$, and that $d \in \mathbf{N}=\{1,2, \ldots\}$ is a positive integer. For $q \in L_{2}\left(I^{2 d}\right)$, let $T_{q}$ be the compact Fredholm operator on $L_{2}\left(I^{d}\right)$ defined by

$$
T_{q} v=\int_{I^{d}} q(\cdot, y) v(y) d y, \quad \text { for all } v \in L_{2}\left(I^{d}\right)
$$

We say that $q$ is the kernel of $T_{q}$. Clearly,

$$
\left\|T_{q} v\right\|_{L_{2}\left(I^{d}\right)} \leq\|q\|_{L_{2}\left(I^{2 d}\right)}\|v\|_{L_{2}\left(I^{d}\right)} \text { for all } q \in L_{2}\left(I^{2 d}\right), \quad v \in L_{2}\left(I^{d}\right)
$$

Therefore,

$$
\begin{equation*}
\left\|T_{q}\right\|_{\operatorname{Lin}\left[L_{2}\left(I^{d}\right)\right]} \leq\|q\|_{L_{2}\left(I^{2 d}\right)}, \quad \text { for all } q \in L_{2}\left(I^{2 d}\right) \tag{3}
\end{equation*}
$$

Moreover, if $\|q\|_{L_{2}\left(I^{2 d}\right)}<1$, then the operator $I-T_{q}$ has a bounded inverse, with

$$
\begin{equation*}
\left\|\left(I-T_{q}\right)^{-1}\right\|_{\operatorname{Lin}\left[L_{2}\left(I^{d}\right)\right]} \leq \frac{1}{1-\|q\|_{L_{2}\left(I^{2 d}\right)}} \tag{4}
\end{equation*}
$$

Let $F_{d}$ and $Q_{d}$ be normed linear subspaces whose norms are denoted by $\|\cdot\|_{F_{d}}$ and $\|\cdot\|_{Q_{d}}$, respectively. We assume that $F_{d}$ and $Q_{d}$ are continuously embedded subspaces of $L_{2}\left(I^{d}\right)$ for all $d \in \mathbf{N}$. As we shall
see in Remark 3.1, there is no essential loss of generality in assuming that

$$
\begin{equation*}
\|\cdot\|_{L_{2}\left(I^{d}\right)} \leq\|\cdot\|_{F_{d}} \quad \text { and } \quad\|\cdot\|_{L_{2}\left(I^{d}\right)} \leq\|\cdot\|_{Q_{d}} \tag{5}
\end{equation*}
$$

Given $M_{1} \in(0,1)$, let

$$
Q_{d}^{\mathrm{res}}=\left\{q \in Q_{d}:\|q\|_{Q_{d}} \leq M_{1}\right\} \quad \text { for all } d \in \mathbf{N}
$$

We define a solution operator $S_{d}: F_{d} \times Q_{2 d}^{\mathrm{res}} \rightarrow L_{2}\left(I^{d}\right)$ as $u=S_{d}(f, q) \quad$ if and only if $\quad\left(I-T_{q}\right) u=f$ for all $(f, q) \in F_{d} \times Q_{2 d}^{\text {res }}$.

Note that

$$
S_{d}(\cdot, q)=\left(I-T_{q}\right)^{-1} \in \operatorname{Lin}\left[L_{2}\left(I^{d}\right)\right] \quad \text { for all } q \in Q_{2 d}^{\mathrm{res}}
$$

In particular, for $q=0$, we have $T_{q}=0$, so that

$$
S_{d}(f, 0)=f \quad \text { for all } f \in F_{d}
$$

The operator $S_{d}$ is linear in its first variable but nonlinear in its second variable. Using (4) and (5), we have the a priori bound

$$
\begin{equation*}
\left\|S_{d}(f, q)\right\|_{L_{2}\left(I^{d}\right)} \leq \frac{\|f\|_{L_{2}\left(I^{d}\right)}}{1-M_{1}} \quad \text { for all }(f, q) \in F_{d} \times Q_{2 d}^{\mathrm{res}} \tag{6}
\end{equation*}
$$

Let $B F_{d}$ denote the unit ball of $F_{d}$. We want to approximate $S_{d}(f, q)$ for $(f, q) \in B F_{d} \times Q_{2 d}^{\mathrm{res}}$, using algorithms whose information $N(f, q)$ about a right hand side $f$ and a kernel $q$ consists of finitely many information operations from a class $\Lambda_{d}$ of permissible functionals of $f$ and from a class $\Lambda_{2 d}$ of permissible functionals of $q$. These functionals can be either of the following:

- Linear class. In this case, we are allowing the class of all continuous linear functionals. We write $\Lambda_{d}=\Lambda_{d}^{\text {all }}$ or $\Lambda_{2 d}=\Lambda_{2 d}^{\text {all }}$.
- Standard class. In this case, we are allowing only function values and choose the spaces $F_{d}$ and $Q_{d}$ such that function values are continuous linear functionals. We write $\Lambda_{d}=\Lambda_{d}^{\text {std }}$ or $\Lambda_{2 d}=\Lambda_{2 d}^{\text {std }}$.

That is, for some nonnegative integers $n_{1}$ and $n_{2}$ we have
$N(f, q)=\left[L_{1}(f), L_{2}(f), \ldots, L_{n_{1}}(f), L_{n_{1}+1}(q), L_{n_{1}+2}(q), \ldots, L_{n_{1}+n_{2}}(q)\right]$,
where $L_{i} \in \Lambda_{d}$ for $i=1,2, \ldots, n_{1}$, and $L_{i} \in \Lambda_{2 d}$ for $i=n_{1}+1, n_{1}+$ $2, \ldots, n_{1}+n_{2}$. The choice of the functionals $L_{i}$ and the numbers $n_{i}$ may be determined adaptively.

An algorithm $A: B F_{d} \times Q_{2 d}^{\mathrm{res}} \rightarrow L_{2}\left(I^{d}\right)$ approximating the Fredholm problem $S_{d}$ has the form

$$
A(f, q)=\phi(N(f, q))
$$

where $N(f, q)$ is the information about $f$ and $q$ and $\phi: N\left(B F_{d} \times Q_{2 d}^{\mathrm{res}}\right) \rightarrow$ $L_{2}\left(I^{d}\right)$ is a combinatory function that combines this information and produces an approximation to the exact solution. For further discussion, see (e.g.), [16, subsection 3.2].

The (worst case) error of an algorithm is given by

$$
e\left(A, S_{d}\right)=\sup _{(f, q) \in B F_{d} \times Q_{2 d}^{\mathrm{res}}}\left\|S_{d}(f, q)-A(f, q)\right\|_{L_{2}\left(I^{d}\right)}
$$

Let

$$
e\left(n, S_{d}, \Lambda_{d, 2 d}\right)=\inf _{A_{n}} e\left(A_{n}, S_{d}\right)
$$

denote the $n$th minimal worst case error for solving the Fredholm problem. Here, the infimum is over all algorithms $A_{n}$ using at most $n$ information operations of right hand sides from $\Lambda_{d}$ and of kernel functions from $\Lambda_{2 d}$, which we indicate by the shortcut notation $\Lambda_{d, 2 d}$. That is, if we use $n_{1}$ and $n_{2}$ information operations for $f$ and $q$, then $n_{1}+n_{2} \leq n$.

Finally, for $\varepsilon \in(0,1)$, we let

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right)=\inf \left\{n \in \mathbf{N}: e\left(n, S_{d}, \Lambda_{d, 2 d}\right) \leq \varepsilon\right\}
$$

denote the information complexity, i.e., the minimal number of information operations needed to obtain an $\varepsilon$-approximation, i.e., an approximation with error at most $\varepsilon$.

Remark 2.1. The (total) complexity of a problem is defined to be the minimal cost of computing an approximation. We will discuss the total complexity of the Fredholm problem later.

Remark 2.2. In this paper, we will only deal with the absolute error criterion. One could also use the normalized error criterion, in which

$$
n^{\mathrm{nor}}\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right)=\inf \left\{n \in \mathbf{N}: e\left(n, S_{d}, \Lambda_{d, 2 d}\right) \leq \varepsilon \cdot e\left(0, S_{d}, \Lambda_{d, 2 d}\right)\right\}
$$

where $e\left(0, S_{d}, \Lambda_{d, 2 d}\right)$ is the initial error, i.e., the minimal error we can achieve without doing any information operations whatsoever. Under the normalized error criterion, we would be trying to determine the minimal number of information operations needed to reduce the initial error by a factor of $\varepsilon$. For simplicity, we restrict ourselves to the absolute error criterion in this paper. See [10, subsection 4.4] for further discussion of error criteria.

How hard is it to solve our problem for large $d$ ? We have the following tractability hierarchy for the problem $S=\left\{S_{d}\right\}_{d \in \mathbf{N}}$, see (e.g.), [10, subsection 4.4]:

1. Problem $S$ is strongly polynomially tractable if $C \geq 0$ and $p \geq 0$ exist such that

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq C \varepsilon^{-p} \quad \text { for all } d \in \mathbf{N}, \varepsilon \in(0,1)
$$

Should this be the case, the infimum of all $p$ such that this holds is said to be the exponent of strong (polynomial) tractability.
2. Problem $S$ is polynomially tractable if $C \geq 0$ and $p, q \geq 0$ exist such that

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq C \varepsilon^{-p} d^{q} \quad \text { for all } d \in \mathbf{N}, \varepsilon \in(0,1)
$$

We can speak of $\varepsilon^{-1}$ - and $d$-tractability exponents for a tractable problem. However, these need not be uniquely determined; for example, we can sometimes decrease one of the exponents by allowing the other exponent to increase.
3. Problem $S$ is quasi-polynomially tractable if there $C \geq 0$ and $t \geq 0$ exist such that

$$
\begin{align*}
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq C \exp \left(t\left(1+\ln \varepsilon^{-1}\right)\right. & (1+\ln d))  \tag{7}\\
& \text { for all } d \in \mathbf{N}, \varepsilon \in(0,1)
\end{align*}
$$

The infimum of all $t$ such that (7) holds is said to be the exponent of quasi-polynomial tractability. Quasi-polynomially tractability was introduced in [6]. The function appearing on the right hand side of (7) is in some sense the smallest non-exponential tractability function $T$ for which the approximation problem for unweighted tensor product spaces is $T$-tractable (see below).
4. Let $\Omega$ be an unbounded subset of $[1, \infty) \times[1, \infty)$. Let $T:[1, \infty) \times$ $[1, \infty) \rightarrow[1, \infty)$ be a function that is non-decreasing in both its variables and that exhibits sub-exponential behavior, i.e.,

$$
\lim _{\substack{\xi, \eta) \in \Omega \\ \xi+\eta \rightarrow \infty}} \frac{\ln T(\xi, \eta)}{\xi+\eta}=0
$$

The set $\Omega$ is called a tractability domain, and $T$ a tractability function. Problem $S$ is $(T, \Omega)$-tractable if $C \geq 0$ and $t \geq 0$ exist such that

$$
\begin{equation*}
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq C T\left(\varepsilon^{-1}, d\right)^{t} \quad \text { for all }\left(\varepsilon^{-1}, d\right) \in \Omega \tag{8}
\end{equation*}
$$

The infimum of all $t$ for which this holds is said to be the exponent of ( $T, \Omega$ )-tractability.
If the right hand side of (8) holds with $d=1$, so that

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq C T\left(\varepsilon^{-1}, 1\right)^{t} \quad \text { for all }\left(\varepsilon^{-1}, d\right) \in \Omega
$$

then $S$ is strongly $(T, \Omega)$-tractable. In such a case, the infimum of all $t$ for which this holds is said to be the exponent of strong $(T, \Omega)$ tractability.
5. Problem $S$ is weakly tractable if

$$
\lim _{\varepsilon^{-1}+d \rightarrow \infty} \frac{\ln n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right)}{\varepsilon^{-1}+d}=0
$$

A weakly tractable problem is one whose information complexity grows sub-exponentially in both $\varepsilon^{-1}$ and $d$.
If problem $S$ is not even weakly tractable, then its information complexity is exponential in either $\varepsilon^{-1}$ or $d$. We say that $S$ is intractable. If the information complexity is exponential in $d$, we follow [2] and say that it suffers from the curse of dimensionality.
3. Tractability of Fredholm vs. tractability of approximation. In this section, we show that tractability of the Fredholm problem is strongly related to tractability of the $L_{2}$-approximation problems over $F_{d}$ and $Q_{d}$. Here, the $L_{2}$-approximation problem over $V_{d}$, where $V_{d}$ is a normed linear space that is continuously embedded in $L_{2}\left(I^{d}\right)$, is defined as approximating the canonical injection $\mathrm{APP}_{V_{d}}: V_{d} \rightarrow L_{2}\left(I^{d}\right)$ given by

$$
\mathrm{APP}_{V_{d}} v=v \quad \text { for all } v \in V_{d}
$$

We approximate $v$ from the unit ball $B V_{d}$ of $V_{d}$, with error being measured in the $L_{2}\left(I^{d}\right)$-norm. Algorithm errors, minimal errors and information complexity for the $L_{2}$-approximation problem over $V_{d}$ are all defined analogously to the way they were defined for the Fredholm problem; the same is true for the various kinds of tractability for $\mathrm{APP}_{V}=\left\{\mathrm{APP}_{V_{d}}\right\}_{d \in \mathbf{N}}$, as well as intractability. Our assumption (5) is equivalent to requiring that

$$
\begin{equation*}
\left\|\mathrm{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]} \leq 1 \quad \text { and } \quad\left\|\mathrm{APP}_{Q_{d}}\right\|_{\operatorname{Lin}\left[Q_{d} ; L_{2}\left(I^{d}\right)\right]} \leq 1 \tag{9}
\end{equation*}
$$

so that the initial errors of the $L_{2}$-approximation problems over $F_{d}$ and $Q_{d}$ are at most one. Note that if the bounds in (5) are sharp, then we have equality in (9), and then the $L_{2}$-approximation problems over $F_{d}$ and $Q_{d}$ are properly scaled.
3.1. Lower bounds. We are ready to prove lower bounds for the Fredholm problem. First, we show that the Fredholm problem $S_{d}$ is not easier than the $L_{2}$-approximation problem over $F_{d}$.

## Proposition 3.1. We have

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \geq n\left(\varepsilon, A P P_{F_{d}}, \Lambda_{d}\right) \quad \text { for all } \varepsilon \in(0,1), d \in \mathbf{N}
$$

Proof. Let $A_{n}$ be an algorithm for approximating the Fredholm problem $S_{d}$ such that $e\left(A_{n}, S_{d}\right) \leq \varepsilon$, using $n$ information operations from $\Lambda_{d, 2 d}$. Define an algorithm $\widetilde{A}_{n}$ for $\mathrm{APP}_{F_{d}}$ by

$$
\widetilde{A}_{n}(f)=A_{n}(f, 0) \quad \text { for all } f \in B F_{d}
$$

Since $\operatorname{APP}_{F_{d}}=S_{d}(\cdot, 0)$, we have

$$
e\left(\widetilde{A}_{n}, \mathrm{APP}_{F_{d}}\right) \leq e\left(A_{n}, S_{d}\right) \leq \varepsilon
$$

which suffices to establish the desired inequality.

We now wish to show that the Fredholm problem $S_{d}$ is not easier than the $L_{2}$-approximation problem over $Q_{d}$. Before doing so, we need a bit of preparation. For a function $q: I^{d} \rightarrow \mathbf{R}$, let us define functions $q_{X}, q_{Y}: I^{2 d} \rightarrow \mathbf{R}$ by

$$
q_{X}(x, y)=q(x) \quad \text { and } \quad q_{Y}(x, y)=q(y), \quad \text { for all } x, y \in I^{d}
$$

We say that the sequence of spaces $Q=\left\{Q_{d}\right\}_{d \in \mathbf{N}}$ satisfies the extension property if for all $d \in \mathbf{N}$, we have

$$
q \in Q_{d} \Longrightarrow q_{X}, q_{Y} \in Q_{2 d}, \quad \text { for all } q \in Q_{d}
$$

with

$$
\begin{equation*}
\left\|q_{X}\right\|_{Q_{2 d}} \leq\|q\|_{Q_{d}} \quad \text { and } \quad\left\|q_{y}\right\|_{Q_{2 d}} \leq\|q\|_{Q_{d}} . \tag{10}
\end{equation*}
$$

Let

$$
\begin{equation*}
M_{2}=\frac{2\left(1+M_{1}\right)\left(3-M_{1}^{2}\right)}{M_{1}\left(1-M_{1}\right)} . \tag{11}
\end{equation*}
$$

Clearly, $M_{2}>1$ and goes to infinity as $M_{1}$ goes to zero. Using Mathematica, we checked that

$$
M_{2} \geq 32.7757 \ldots
$$

taking its minimal value when

$$
\begin{aligned}
M_{1}= & \frac{1}{2}-\frac{1}{2} \sqrt{-\frac{1}{3}+\frac{1}{3} \sqrt[3]{656-72 \sqrt{83}}+\frac{2}{3} \sqrt[3]{82+9 \sqrt{83}}} \\
& +\frac{1}{2} \sqrt{\frac{1}{3}\left(-2-\sqrt[3]{656-72 \sqrt{83}}-2 \sqrt[3]{82+9 \sqrt{83}}+\frac{42}{\sqrt{-\frac{1}{3}+\frac{1}{3} \sqrt[3]{656-72 \sqrt{83}}+\frac{2}{3} \sqrt[3]{82+9 \sqrt{83}}}}\right)} \\
& \doteq 0.455213
\end{aligned}
$$

Proposition 3.2. Suppose that $Q$ satisfies the extension property, and that $1 \in B F_{d}$. Then

$$
\begin{aligned}
& n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \geq n\left(M_{2} \varepsilon, A P P_{Q_{d}}, \Lambda_{d}\right) \\
& \qquad \text { for all } \varepsilon \in\left(0, \frac{1}{2\left(1+M_{1}\right)}\right], d \in \mathbf{N} .
\end{aligned}
$$

Proof. For $q \in B Q_{d}$, the extension property tells us that $M_{1} q_{X}, M_{1} q_{Y} \in$ $Q_{2 d}^{\mathrm{res}}$. As in [12, subsection 18.2.1], we have

$$
\begin{equation*}
S_{d}\left(1, M_{1} q_{Y}\right)=\frac{1}{1-M_{1} \int_{I^{d}} q(y) d y} \tag{12}
\end{equation*}
$$

Moreover, it is easy to see that

$$
S_{d}\left(1, M_{1} q_{X}\right)=\frac{M_{1} q}{1-M_{1} \int_{I^{d}} q(y) d y}+1
$$

Combining these results and solving for $q$, we see that

$$
\begin{equation*}
q=\frac{S_{d}\left(1, M_{1} q_{X}\right)-1}{M_{1} S_{d}\left(1, M_{1} q_{Y}\right)}=\frac{S_{d}\left(1, M_{1} q_{X}\right)-1}{M_{1} \int_{I^{d}} S_{d}\left(1, M_{1} q_{Y}\right) d y} \tag{13}
\end{equation*}
$$

the latter holding because (12) tells us that $S_{d}\left(1, M_{1} q_{Y}\right)$ is a number. Now let $A_{n}$ be an algorithm for approximating $S_{d}$ over $B F_{d} \times Q_{2 d}^{\text {res }}$ such that it uses $n$ information operations from $\Lambda_{d, 2 d}$ and $e\left(A_{n}, S_{d}\right) \leq \varepsilon$, where

$$
\varepsilon \leq \frac{1}{2\left(1+M_{1}\right)}
$$

Guided by (13), we define an algorithm $\widetilde{A}_{n}$ for approximating $\mathrm{APP}_{Q_{d}}$ by

$$
\widetilde{A}_{n} q=\frac{A_{n}\left(1, M_{1} q_{X}\right)-1}{M_{1} \int_{I^{d}} A_{n}\left(1, M_{1} q_{Y}\right)(y) d y}, \quad \text { for all } q \in B Q_{d}
$$

We now compute an upper bound on the error of $\widetilde{A}_{n}$. First, some algebra yields that

$$
\begin{align*}
& q-\widetilde{A}_{n} q=\frac{1}{M_{1} \int_{I^{d}} A_{n}\left(1, M_{1} q_{Y}\right)(y) d y}\left[S_{d}\left(1, M_{1} q_{X}\right)-A_{n}\left(1, M_{1} q_{X}\right)\right.  \tag{14}\\
&+\left(\frac{1-S_{d}\left(1, M_{1} q_{X}\right)}{S_{d}\left(1, M_{1} q_{Y}\right)}\right) \\
&\left.\quad \times \int_{I^{d}}\left[S_{d}\left(1, M_{1} q_{Y}\right)-A_{n}\left(1, M_{1} q_{Y}\right)(y)\right] d y\right]
\end{align*}
$$

Using the inequality

$$
\begin{aligned}
&\left|\int_{I^{d}}\left[S_{d}\left(1, M_{1} q_{Y}\right)-A_{n}\left(1, M_{1} q_{Y}\right)(y)\right] d y\right| \\
& \leq\left\|S_{d}\left(1, M_{1} q_{Y}\right)-A_{n}\left(1, M_{1} q_{Y}\right)\right\|_{L_{2}\left(I^{d}\right)}
\end{aligned}
$$

along with the fact that $e\left(A_{n}, S_{d}\right) \leq \varepsilon$, equation (14) yields the inequality

$$
\begin{align*}
&\left\|q-\widetilde{A}_{n} q\right\|_{L_{2}\left(I^{d}\right)} \leq \frac{1}{M_{1}\left|\int_{I^{d}} A_{n}\left(1, M_{1} q_{Y}\right)(y) d y\right|}  \tag{15}\\
& \times\left[\left\|S_{d}\left(1, M_{1} q_{X}\right)-A_{n}\left(1, M_{1} q_{X}\right)\right\|_{L_{2}\left(I^{d}\right)}\right. \\
&+\frac{1+\left\|S_{d}\left(1, M_{1} q_{X}\right)\right\|_{L_{2}\left(I^{d}\right)}}{\left|S_{d}\left(1, M_{1} q_{Y}\right)\right|} \| S_{d}\left(1, M_{1} q_{Y}\right) \\
&\left.-A_{n}\left(1, M_{1} q_{Y}\right) \|_{L_{2}\left(I^{d}\right)}\right] \\
& \leq \frac{1}{M_{1}\left|\int_{I^{d}} A_{n}\left(1, M_{1} q_{Y}\right)(y) d y\right|} \\
& \quad \times\left[1+\frac{1+\left\|S_{d}\left(1, M_{1} q_{X}\right)\right\|_{L_{2}\left(I^{d}\right)}}{\left|S_{d}\left(1, M_{1} q_{Y}\right)\right|}\right] \cdot \varepsilon
\end{align*}
$$

Since $M_{1} q_{X} \in Q_{2 d}^{\mathrm{res}}$, we have

$$
\left\|S_{d}\left(1, M_{1} q_{x}\right)\right\|_{L_{2}\left(I^{d}\right)} \leq \frac{1}{1-M_{1}}
$$

Since $M_{1} q_{Y} \in Q_{2 d}^{\mathrm{res}}$ and $S_{d}\left(1, M_{1} q_{Y}\right) \in \mathbf{R}$, we have

$$
\frac{1}{1+M_{1}} \leq S_{d}\left(1, M_{1} q_{Y}\right) \leq \frac{1}{1-M_{1}}
$$

Now our restriction on $\varepsilon$ implies that

$$
\begin{aligned}
\left|\int_{I^{d}} A_{n}\left(1, M_{1} q_{Y}\right)(y) d y\right| & \geq S_{d}\left(1, M_{1} q_{Y}\right) \\
& -\left|\int_{I^{d}}\left[S_{d}\left(1, M_{1} q_{Y}\right)-A_{n}\left(1, M_{1} q_{Y}\right)(y)\right] d y\right| \\
& \geq \frac{1}{1+M_{1}}-\varepsilon \geq \frac{1}{2\left(1+M_{1}\right)}
\end{aligned}
$$

Substituting these last three inequalities into (15), we find

$$
\begin{aligned}
\left\|q-\widetilde{A}_{n} q\right\|_{L_{2}\left(I^{d}\right)} & \leq \frac{2\left(1+M_{1}\right)}{M_{1}}\left[1+\left(1+\frac{1}{1-M_{1}}\right)\left(1+M_{1}\right)\right] \varepsilon \\
& =M_{2} \cdot \varepsilon
\end{aligned}
$$

Since $q$ is an arbitrary element of $B Q_{d}$, we see that

$$
e\left(\widetilde{A}_{n}, S_{d}\right) \leq M_{2} \cdot \varepsilon
$$

This suffices to establish the desired inequality.

Using Propositions 3.1 and 3.2 , we have the following corollary.

Corollary 3.1. Suppose that $Q$ satisfies the extension property and that $1 \in B F_{d}$. Then the Fredholm problem $S$ is at least as hard as the approximation problems $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$; equivalently $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$ are at most as hard as $S$. That is:

1. If the Fredholm problem $S$ is strongly polynomially tractable, then so are $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$. Moreover, the exponents of strong polynomial tractability of the approximation problems are no larger than those for the Fredholm problem.
2. If the Fredholm problem $S$ is polynomially tractable, then so are $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$. Moreover, $\varepsilon^{-1}$ - and d-exponents for the approximation problems are no larger than those for the Fredholm problem.
3. If the Fredholm problem $S$ is quasi-polynomially tractable, then so are $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$. The exponent of quasi-polynomial tractability for the approximation problem $\mathrm{APP}_{F}$ is no larger than this for the Fredholm problem. However, the exponent of quasi-polynomial tractability for the approximation problem $\mathrm{APP}_{Q}$ may be larger than this for the Fredholm problem by the factor $\left(1+\ln M_{2}\right)\left(1+\ln 2\left(1+M_{1}\right)\right)$.
4. Suppose that, for all $\boldsymbol{\alpha}>0$, the tractability function $T$ satisfies

$$
\begin{equation*}
T(\boldsymbol{\alpha} \xi, \eta)=\mathscr{O}(T(\xi, \eta)) \quad \text { as } \xi, \eta \rightarrow \infty \tag{16}
\end{equation*}
$$

If the Fredholm problem $S$ is (strongly) ( $T, \Omega$ )-tractable, then so are $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$. Moreover, the exponents of (strong) $(T, \Omega)$-tractability
for the approximation problems are no larger than those for the Fredholm problem.
5. If the Fredholm problem $S$ is weakly tractable, then so are $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$.
6. If either $\mathrm{APP}_{F}$ or $\mathrm{APP}_{Q}$ are intractable, then so is the Fredholm problem $S$.

Proof. All of these statements follow from Propositions 3.1 and 3.2. However the statements regarding quasi-polynomial tractability and $(T, \Omega)$-tractability are a bit more subtle than the others, so we give some details for these cases.

Suppose first that the Fredholm problem $S$ is quasi-polynomially tractable. This means that $C>0$ and $t \geq 0$ exist such that

$$
\begin{aligned}
& n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq C \exp \left(t\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\right) \\
& \quad \text { for all } d \in \mathbf{N}, \quad \varepsilon \in(0,1) .
\end{aligned}
$$

From Proposition 3.1, we immediately find that $\mathrm{APP}_{F}$ is quasipolynomially tractable, with the same estimate

$$
\begin{aligned}
& n\left(\varepsilon, \mathrm{APP}_{F_{d}}, \Lambda_{d}\right) \leq n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \\
& \leq C \exp \left(t\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\right) \\
& \quad \text { for all } d \in \mathbf{N}, \quad \varepsilon \in(0,1)
\end{aligned}
$$

What about $\mathrm{APP}_{Q}$ ? Proposition 3.2 yields that

$$
\begin{aligned}
& n\left(M_{2} \varepsilon, \operatorname{APP}_{Q_{d}}, \Lambda_{d}\right) \leq n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \\
& \\
& \quad \text { for all } d \in \mathbf{N}, \quad \varepsilon \in\left(0,1 /\left(2\left(1+M_{1}\right)\right)\right]
\end{aligned}
$$

For $\varepsilon \in\left(0,1 /\left(2\left(1+M_{1}\right)\right)\right.$, we replace $M_{2} \varepsilon$ by $\varepsilon$. Remembering that $M_{2}>1$, we get

$$
\begin{aligned}
n\left(\varepsilon, \operatorname{APP}_{Q_{d}}, \Lambda_{d}\right) & \leq n\left(M_{2}^{-1} \varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \\
& \leq C \exp \left[t\left(1+\ln M_{2}+\ln \varepsilon^{-1}\right)(1+\ln d)\right] \\
& =C \exp \left[t\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\left(1+\frac{\ln M_{2}}{1+\ln \varepsilon^{-1}}\right)\right] \\
& \leq C \exp \left(t\left(1+\ln M_{2}\right)\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\right)
\end{aligned}
$$

For $\varepsilon \in\left(1 /\left(2\left(1+M_{1}\right)\right), 1\right)$, we simply estimate

$$
\begin{aligned}
n\left(\varepsilon, \operatorname{APP}_{Q_{d}}, \Lambda_{d}\right) & \leq n\left(\frac{1}{2\left(1+M_{1}\right)}, \operatorname{APP}_{Q_{d}}, \Lambda_{d}\right) \\
& \leq C \exp \left(t\left(1+\ln M_{2}\right)\left[1+\ln 2\left(1+M_{1}\right)\right](1+\ln d)\right)
\end{aligned}
$$

Hence, $\mathrm{APP}_{Q}$ is quasi-polynomially tractable, with an exponent at most $t\left(1+\ln M_{2}\right)\left[1+\ln 2\left(1+M_{1}\right)\right]$. This exponent is clearly larger than that of the Fredholm problem.

Now suppose that the Fredholm problem $S$ is (strongly) $(T, \Omega)$ tractable, with a tractability function $T$ satisfying (16). For $\mathrm{APP}_{F}$, we find that

$$
\begin{aligned}
& n\left(\varepsilon, \operatorname{APP}_{F_{d}}, \Lambda_{d}\right) \leq n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right)=T\left(\varepsilon^{-1}, d\right)^{t} \\
& \quad \text { for all } d \in \mathbf{N}, \quad \varepsilon \in(0,1)
\end{aligned}
$$

For $\mathrm{APP}_{Q}$, we find that for all $d \in \mathbf{N}$ and $\varepsilon \in(0,1)$, we have

$$
\begin{aligned}
n\left(\varepsilon, \operatorname{APP}_{Q_{d}}, \Lambda_{d}\right) & \leq n\left(M_{2}^{-1} \min \left\{\varepsilon, \frac{1}{2\left(1+M_{1}\right)}\right\}, S_{d}, \Lambda_{d, 2 d}\right) \\
& =\mathscr{O}\left(T\left(M_{2}\left[\min \left\{\varepsilon, \frac{1}{2\left(1+M_{1}\right)}\right\}\right]^{-1}, d\right)^{t}\right)
\end{aligned}
$$

Since

$$
\frac{1}{\min \left\{\varepsilon, 1 /\left(2\left(1+M_{1}\right)\right)\right\}} \leq \frac{2\left(1+M_{1}\right)}{\varepsilon}
$$

we finally obtain

$$
n\left(\varepsilon, \operatorname{APP}_{Q_{d}}, \Lambda_{d}\right)=\mathscr{O}\left(T\left(\varepsilon^{-1}, d\right)^{t}\right), \quad \text { for all } d \in \mathbf{N}, \varepsilon \in(0,1)
$$

Thus, both approximation problems are (strongly) $(T, \Omega)$-tractable, with exponents at most as large as the exponent for the Fredholm problem, as claimed.
3.2. Upper bounds. Having found lower bounds, we now look for analogous upper bounds.

Lemma 3.1. Let $u=S_{d}(f, q)$ and $\widetilde{u}=S_{d}(\tilde{f}, \widetilde{q})$ for $(f, q),(\widetilde{f}, \widetilde{q}) \in$ $B F_{d} \times Q_{2 d}^{\mathrm{res}}$. Then

$$
\|u-\widetilde{u}\|_{L_{2}\left(I^{d}\right)} \leq \frac{1}{1-M_{1}}\left[\|f-\widetilde{f}\|_{L_{2}\left(I^{d}\right)}+\|u\|_{L_{2}\left(I^{d}\right)}\|q-\widetilde{q}\|_{L_{2}\left(I^{2 d}\right)}\right]
$$

Proof. Since $\left(I-T_{q}\right) u=f$ and $\left(I-T_{\tilde{q}}\right) \widetilde{u}=\widetilde{f}$, we find that

$$
f-\widetilde{f}=u-\widetilde{u}-T_{q} u+T_{\tilde{q}} \widetilde{u}=u-\widetilde{u}-T_{q-\tilde{q}} u-T_{\tilde{q}}(u-\widetilde{u})
$$

and so,

$$
\left(I-T_{\tilde{q}}\right)(u-\widetilde{u})=f-\tilde{f}+T_{q-\tilde{q}} u
$$

Hence,

$$
u-\widetilde{u}=\left(I-T_{\tilde{q}}\right)^{-1}\left[f-\tilde{f}+T_{q-\tilde{q}} u\right] .
$$

Using (3) and (4), we get the desired inequality.

We now use Lemma 3.1 to find upper bounds for the Fredholm problem, in terms of upper bounds for the $L_{2}$-approximation problems for $F_{d}$ and $Q_{d}$.

Proposition 3.3. For $\varepsilon>0$ and $d \in \mathbf{N}$, we have

$$
\begin{align*}
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq & n\left(\frac{\left(1-M_{1}\right) \varepsilon}{2}, \operatorname{APP}_{F_{d}}, \Lambda_{d}\right) \\
& +n\left(\frac{\left(1-M_{1}\right)^{2} \varepsilon}{2 M_{1}}, \operatorname{APP}_{Q_{2 d}}, \Lambda_{2 d}\right) \tag{17}
\end{align*}
$$

Proof. Let $\widetilde{A}_{n(F), F_{d}}$ and $\widetilde{A}_{n(Q), Q_{2 d}}$ (respectively) be algorithms using $n(F)$ and $n(Q)$ information operations for the $L_{2}$-approximation problems over $F_{d}$ and $Q_{2 d}$ such that

$$
\begin{equation*}
e\left(\widetilde{A}_{n(F), F_{d}}, \mathrm{APP}_{F_{d}}\right) \leq \frac{\left(1-M_{1}\right) \varepsilon}{2} \tag{18}
\end{equation*}
$$

and

$$
e\left(\widetilde{A}_{n(Q), Q_{2 d}}, \operatorname{APP}_{Q_{2 d}}\right) \leq \frac{\left(1-M_{1}\right)^{2} \varepsilon}{2 M_{1}}
$$

Let $n=n(F)+n(Q)$. Define an algorithm $A_{n}$ for the Fredholm problem as
$A_{n}(f, q)=S_{d}\left(\widetilde{A}_{n(F), F_{d}}(f), \widetilde{A}_{n(Q), Q_{2 d}}(q)\right) \quad$ for all $(f, q) \in B F_{d} \times Q_{2 d}^{\mathrm{res}}$.
Clearly, $A_{n}$ uses $n$ information operations. To compute the error of $A_{n}$, let $(f, q) \in B F_{d} \times Q_{2 d}^{\mathrm{res}}$. By (18), we have

$$
\left\|f-\widetilde{A}_{n(F), F_{d}}(f)\right\|_{L_{2}\left(I^{d}\right)} \leq \frac{\left(1-M_{1}\right) \varepsilon}{2}\|f\|_{F_{d}} \leq \frac{\left(1-M_{1}\right) \varepsilon}{2}
$$

and

$$
\left\|q-\widetilde{A}_{n(Q), Q_{2 d}}(q)\right\|_{L_{2}\left(I^{2 d}\right)} \leq \frac{\left(1-M_{1}\right)^{2} \varepsilon}{2 M_{1}}\|q\|_{Q_{2 d}} \leq \frac{\left(1-M_{1}\right)^{2} \varepsilon}{2}
$$

Using Lemma 3.1 and inequality (6), we now have

$$
\begin{aligned}
e\left(A_{n}, S_{d}\right) \leq & \frac{1}{1-M_{1}}\left[\left\|f-\widetilde{A}_{n(F), F_{d}}\right\|_{L_{2}\left(I^{d}\right)}\right. \\
& \left.+\left\|S_{d}(f, q)\right\|_{L_{2}\left(I^{d}\right)}\left\|q-\widetilde{A}_{n(Q), Q_{2 d}}(q)\right\|_{L_{2}\left(I^{2 d}\right)}\right] \\
\leq & \frac{1}{1-M_{1}}\left(\frac{\left(1-M_{1}\right) \varepsilon}{2}+\frac{1}{1-M_{1}} \frac{\left(1-M_{1}\right)^{2} \varepsilon}{2}\right) \\
= & \varepsilon .
\end{aligned}
$$

Since $(f, q)$ is an arbitrary element of $B F_{d} \times Q_{2 d}^{\text {res }}$, we see that

$$
e\left(A_{n}, S_{d}\right) \leq \varepsilon
$$

The algorithms $\widetilde{A}_{n(F), F_{d}}$ and $\widetilde{A}_{n(Q), Q_{2 d}}$ are arbitrary and satisfy (18). We can then take them to be algorithms using the minimal number of information operations needed to satisfy (18). Inequality (17) now follows.

We now discuss the arguments of $n\left(\cdot, \mathrm{APP}_{F_{d}}, \Lambda_{d}\right)$ and $n\left(\cdot, \mathrm{APP}_{Q_{2 d}}\right.$, $\left.\Lambda_{2 d}\right)$ in (17). For all $\varepsilon \in(0,1)$, the argument $\left(1-M_{1}\right) \varepsilon / 2$ is less than $1 / 2$; however, the argument $\left(1-M_{1}\right)^{2} \varepsilon /\left(2 M_{1}\right)$ may be larger than one if $M_{1}$ is small enough and $\varepsilon$ close enough to one. In this case, the second term

$$
n\left(\frac{\left(1-M_{1}\right)^{2} \varepsilon}{2 M_{1}}, \operatorname{APP}_{Q_{2 d}}, \Lambda_{2 d}\right)=0 \quad \text { for } \frac{\left(1-M_{1}\right)^{2} \varepsilon}{2 M_{1}} \geq 1
$$

since we now can take $A_{0}=0$ with error at most 1 .
Using Proposition 3.3, we have the following corollary.

Corollary 3.2. Fredholm problem $S$ is no harder than the approximation problems $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$. That is:

1. If $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$ are strongly polynomially tractable, then so is the Fredholm problem $S$. Moreover, the exponent of strong polynomial tractability for $S$ is no larger than the greater of those for $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$.
2. If $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$ are polynomially tractable, then so is the Fredholm problem $S$. Moreover, the $\varepsilon^{-1}$-exponents and the $d$-exponents for $S$ are no larger than the greater of the $\varepsilon^{-1}$-exponents and the $d$ exponents for $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$.
3. If $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$ are quasi-polynomially tractable, then so is the Fredholm problem $S$. Moreover, the exponent $t_{S}$ of quasi-polynomial tractability for $S$ satisfies

$$
\begin{align*}
t_{S} \leq t_{S}^{*}:=\max \{ & t_{F}\left(1+\ln \frac{2}{1-M_{1}}\right)  \tag{19}\\
& \left.t_{Q}\left(1+\max \left\{0, \ln \frac{2 M_{1}}{\left(1-M_{1}\right)^{2}}\right\}\right)(1+\ln 2)\right\}
\end{align*}
$$

4. Suppose that the following are true:
(a) $\mathrm{APP}_{F}$ is (strongly) $\left(T_{F}, \Omega\right)$-tractable, with (strong) exponent $t_{F}$.
(b) $\mathrm{APP}_{Q}$ is (strongly) $\left(T_{Q}, \Omega\right)$-tractable, with (strong) exponent $t_{Q}$.
(c) For any $\boldsymbol{\alpha}>0$, the tractability functions $T_{F}$ and $T_{Q}$ satisfy

$$
T_{F}(\boldsymbol{\alpha} \xi, \eta)=\mathscr{O}\left(T_{F}(\xi, \eta)\right)
$$

and

$$
T_{Q}(\boldsymbol{\alpha} \xi, \eta)=\mathscr{O}\left(T_{Q}(\xi, \eta)\right) \quad \text { as } \xi, \eta \rightarrow \infty
$$

Then
(a) Fredholm problem $S$ is $\left(T_{S}, \Omega\right)$-tractable, with $T_{S}=\max \left\{T_{F}, T_{Q}\right\}$. Moreover, strong $\left(T_{S}, \Omega\right)$-tractability holds for $S$ if and only if it holds for both $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$.
(b) The (strong) exponent of $\left(T_{S}, \Omega\right)$-tractability is at most $\max \left\{t_{F}, t_{Q}\right\}$.
5. If $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$ are weakly tractable, then so is Fredholm problem $S$.
6. If Fredholm problem $S$ is intractable, then either $\mathrm{APP}_{F}$ is intractable or $\mathrm{APP}_{Q}$ is intractable.

Proof. All this follows from Proposition 3.3 (as mentioned above), along with definitions of the various kinds of tractability. To illustrate, we prove the quasi-polynomial case (part 3) for no other reason than to explain the somewhat odd looking result for $t_{S}^{*}$.

Since $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$ are quasi-polynomially tractable, positive $C_{F}$ and $C_{Q}$ exist, as well as nonnegative $t_{F}$ and $t_{Q}$, such that

$$
n\left(\varepsilon, \mathrm{APP}_{F_{d}}, \Lambda_{d}\right) \leq C_{F} \exp \left(t_{F}\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\right)
$$

and

$$
n\left(\varepsilon, \operatorname{APP}_{Q_{2 d}}, \Lambda_{2 d}\right) \leq C_{Q} \exp \left(t_{Q}\left(1+\ln \varepsilon^{-1}\right)(1+\ln 2 d)\right)
$$

$$
\begin{align*}
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq & C_{F} \exp \left(t_{F}\left[1+\ln \left(\frac{\left(1-M_{1}\right) \varepsilon}{2}\right)^{-1}\right](1+\ln d)\right)  \tag{20}\\
& +\delta_{\varepsilon} C_{Q} \exp \left(t_{Q}\left[1+\ln \left(\frac{\left(1-M_{1}\right)^{2} \varepsilon}{2 M_{1}}\right)^{-1}\right](1+\ln 2 d)\right)
\end{align*}
$$

where $\delta_{\varepsilon}=0$ for $\left(1-M_{1}\right)^{2} \varepsilon /\left(2 M_{1}\right) \geq 1$, and $\delta_{\varepsilon}=1$, otherwise.
Clearly, for $c \in(0,1]$, we have

$$
1+\ln (c \varepsilon)^{-1} \leq\left(1+\ln \varepsilon^{-1}\right)\left(1+\ln c^{-1}\right), \quad \text { for all } \varepsilon \in(0,1)
$$

as well as

$$
1+\ln 2 d \leq(1+\ln 2)(1+\ln d), \quad \text { for all } d \in \mathbf{N} .
$$

Applying these inequalities to (20), we conclude that

$$
\begin{aligned}
& n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq C_{F} \exp \left(t_{F}\left(1+\ln \frac{2}{1-M_{1}}\right)\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\right) \\
& +C_{Q} \exp \left(t_{Q}\left(1+\max \left\{0, \ln \frac{2 M_{1}}{\left(1-M_{1}\right)^{2}}\right\}\right)\right. \\
& \left.\times(1+\ln 2)\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\right) .
\end{aligned}
$$

Using this we get the formula for $t_{S}^{*}$.
The proof of the remaining parts of the corollary is easy.

Remark 3.1. In Section 2, we said that there was no essential loss of generality in assuming that (5) (equivalently, (9)) holds. To see why this is true, note the following:

- If $\left\|\mathrm{APP}_{F_{d}}\right\|_{\text {Lin }\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}>1$, the bound (17) in Proposition 3.3 becomes

$$
\begin{aligned}
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \leq & n\left(\frac{\left(1-M_{1}\right) \varepsilon}{2}, \operatorname{APP}_{F_{d}}, \Lambda_{d}\right) \\
& +n\left(\frac{\left(1-M_{1}\right)^{2} \varepsilon}{2 M_{1}\left\|\mathrm{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}}, \operatorname{APP}_{Q_{2 d}}, \Lambda_{d}\right)
\end{aligned}
$$

Hence, if $\sup _{d \in \mathbf{N}}\left\|\mathrm{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}<\infty$, then

$$
\begin{aligned}
& n\left(\frac{\left(1-M_{1}\right)^{2}}{2\left\|\mathrm{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}} \varepsilon,\left\|\operatorname{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}, \Lambda_{d}\right) \\
\leq & n\left(\frac{\left(1-M_{1}\right)^{2}}{2 M_{1} \sup _{d \in \mathbf{N}}\left\|\mathrm{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}} \varepsilon,\left\|\operatorname{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}, \Lambda_{d}\right) .
\end{aligned}
$$

Thus the tractability results of Corollary 3.2 hold as stated, but with a slight change in the denominator of the first argument of $n\left(\cdot, \mathrm{APP}_{Q_{2 d}}, \Lambda_{d}\right)$. However, if

$$
\sup _{d \in \mathbf{N}}\left\|\mathrm{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}=\infty
$$

then the approximation problem for $F_{d}$ is badly scaled.

- If $\left\|\mathrm{APP}_{Q_{d}}\right\|_{\operatorname{Lin}\left[Q_{d} ; L_{2}\left(I^{d}\right)\right]}>1$, we can renormalize $Q_{d}$ under the (equivalent) norm

$$
\|q\|_{\hat{Q}_{d}}=\sqrt{\|q\|_{L_{2}\left(I^{d}\right)}^{2}+\|q\|_{Q_{d}}^{2}}, \quad \text { for all } q \in Q_{d}
$$

calling the resulting space $\widehat{Q}_{d}$. We now replace $Q_{d}$ by $\widehat{Q}_{d}$ and $Q_{d}^{\text {res }}$ by

$$
\widehat{Q}_{d}^{\mathrm{res}}=\left\{q \in \widehat{Q}_{d}:\|q\|_{\hat{Q}_{d}} \leq M_{1}\right\} .
$$

Since $q \in \widehat{Q}_{d}^{\text {res }}$ implies that $\|q\|_{L_{2}\left(I^{d}\right)} \leq M_{1}$ and $\|q\|_{Q_{d}} \leq M_{1}$, we see that all our results go through as before under this relabeling.
4. Some examples. We now study the tractability of the Fredholm problem for three examples, each being defined by choosing particular spaces of right-hand side functions and kernel functions. The first example shows us that we may be stricken by the curse of dimensionality even if the right-hand side or the kernel function is infinitely smooth. In the second example, we look at unweighted isotropic spaces, finding that the Fredholm problem is quasi-polynomially tractable but not polynomially tractable. In the third example, we explore tractability for a family of weighted spaces, getting both positive and negative results for polynomial tractability.
4.1. Intractability for $C^{\infty}$ functions. Let $C^{\infty}\left(I^{d}\right)$ be the space of infinitely many times differentiable functions with the norm

$$
\|v\|_{C^{\infty}\left(I^{d}\right)}=\sup _{\alpha \in \mathbf{N}_{0}^{d}}\left\|D^{\alpha} v\right\|_{L_{2}\left(I^{d}\right)}
$$

Here, $\boldsymbol{\alpha}=\left(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right) \in \mathbf{N}^{d}$ is a multi-index with $|\boldsymbol{\alpha}|=\sum_{j=1}^{d} \alpha_{j}$, and

$$
D^{\boldsymbol{\alpha}} v=\frac{\partial^{|\boldsymbol{\alpha}|}}{\partial^{\alpha_{1}} x_{1} \partial^{\alpha_{2}} x_{2} \cdots \partial^{\alpha_{d}} x_{d}}
$$

Let $F_{d}=Q_{d}=C^{\infty}\left(I^{d}\right)$. The $L_{2}$-approximation problems for $F_{d}$ and $G_{d}$ satisfy assumption (5). Moreover, since $\|1\|_{F_{d}}=\|1\|_{Q_{d}}=\|1\|_{L_{2}\left(I^{d}\right)}$, we have

$$
\left\|\mathrm{APP}_{F_{d}}\right\|_{\operatorname{Lin}\left[F_{d} ; L_{2}\left(I^{d}\right)\right]}=\left\|\operatorname{APP}_{Q_{d}}\right\|_{\operatorname{Lin}\left[Q_{d} ; L_{2}\left(I^{d}\right)\right]}=1
$$

This also shows that $1 \in B F_{d}$, as needed in Proposition 3.2. Moreover, $Q=\left\{Q_{d}\right\}_{d \in \mathbf{N}}$ satisfies the extension property, with equality holding in (10). This means that we can use all the results presented in the previous section.

The functions in $F_{d}$ and $Q_{d}$ are of unbounded smoothness. As in [11], it is easy to check that, for $\Lambda_{d} \in\left\{\Lambda_{d}^{\text {all }}, \Lambda_{d}^{\text {std }}\right\}$, we have

$$
e\left(n, \mathrm{APP}_{F_{d}}, \Lambda_{d}\right)=\mathscr{O}\left(n^{-r}\right)
$$

and

$$
e\left(n, \mathrm{APP}_{Q_{d}}, \Lambda_{d}\right)=\mathscr{O}\left(n^{-r}\right) \quad \text { as } n \rightarrow \infty
$$

for any $r>0$, no matter how large. This implies that we also have

$$
e\left(n, S_{d}, \Lambda_{d, 2 d}\right)=\mathscr{O}\left(n^{-r}\right) \quad \text { as } n \rightarrow \infty
$$

and

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right)=\mathscr{O}\left(\varepsilon^{-1 / r}\right) \quad \text { as } \varepsilon \rightarrow 0
$$

for the Fredholm problem. Since $r$ can be arbitrarily large, this might lead one to hope that the Fredholm problem does not suffer from the curse of dimensionality in this case. We now crush this hope, showing that the Fredholm problem is intractable if either $F_{d}=C^{\infty}\left(I^{d}\right)$ or $Q_{2 d}=C^{\infty}\left(I^{2 d}\right)$ and $F_{d}$ satisfies (5) as well as $1 \in B F_{d}$. This holds for the class $\Lambda^{\text {all }}$, and therefore also for the class $\Lambda^{\text {std }}$.

First, suppose that $F_{d}=C^{\infty}\left(I^{d}\right)$. Using [18, Proposition 3], we find that

$$
e\left(n, \mathrm{APP}_{F_{d}}, \Lambda_{d}^{\text {all }}\right)=1 \quad \text { for } n<2^{\lceil d / 24\rceil}
$$

Hence, the $L_{2}$-approximation problem over $F_{d}$ is intractable, with

$$
n\left(\varepsilon, \operatorname{APP}_{F_{d}}, \Lambda_{d}^{\text {all }}\right) \geq 2^{\lfloor d / 24\rfloor} \text { for all } \varepsilon \in(0,1)
$$

From Proposition 3.1, we immediately see that

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \geq n\left(\varepsilon, \mathrm{APP}_{F_{d}}, \Lambda_{d}\right) \geq 2^{\lfloor d / 24\rfloor} \quad \text { for all } \varepsilon \in(0,1)
$$

Hence, the Fredholm problem is also intractable.
Now suppose that $Q_{d}=C^{\infty}\left(I^{d}\right)$, and that $F_{d}$ satisfies (5), with $1 \in B F_{d}$. Again using [18, Proposition 3], we find that

$$
e\left(n, \operatorname{APP}_{Q_{2 d}}, \Lambda_{2 d}^{\text {all }}\right)=1, \quad \text { for } n<2^{\lceil d / 12\rceil}
$$

and so the $L_{2}$-approximation problem over $Q_{d}$ is intractable, with

$$
n\left(\varepsilon, \operatorname{APP}_{Q_{d}}, \Lambda_{d}^{\text {all }}\right) \geq 2^{\lfloor d / 12\rfloor}, \quad \text { for all } \varepsilon \in(0,1)
$$

Noting that

$$
\min \left\{\frac{1}{M_{2}}, \frac{1}{2\left(1+M_{1}\right)}\right\}=\frac{1}{M_{2}}
$$

Proposition 3.2 yields that
$n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}\right) \geq n\left(M_{2} \varepsilon, \mathrm{APP}_{Q_{2 d}}, \Lambda_{d}\right) \geq 2^{\lfloor d / 12\rfloor}, \quad$ for all $\varepsilon \in\left(0, \frac{1}{M_{2}}\right]$.
Thus, the Fredholm problem is intractable also in this case.
In short, the Fredholm problem suffers from the curse of dimensionality if $F_{d}=C^{\infty}\left(I^{d}\right)$ or $Q_{d}=C^{\infty}\left(I^{d}\right)$ and $F_{d}$ satisfies (5) as well as $1 \in B F_{d}$. Using these extremely smooth spaces avails us not.
4.2. Results for unweighted tensor product spaces. We now start to explore tractability for tensor product spaces. Our first step is to look at unweighted tensor product Hilbert spaces, as per [10, subsection 5.2]. We will then look at weighted tensor product Hilbert spaces in Section 5.

Since the space for the univariate case is a building block for the tensor product space, we first start with the univariate case and then go on to define the tensor product space for general $d$.

For the univariate case, let $H_{1} \subseteq L_{2}(I)$ be an infinite-dimensional separable Hilbert space of univariate functions. Suppose that the embedding $\mathrm{APP}_{1}: H_{1} \rightarrow L_{2}(I)$ is compact. Then $W_{1}=\mathrm{APP}_{1}^{*} \mathrm{APP}_{1}$ :
$H_{1} \rightarrow H_{1}$ is a compact, self-adjoint, positive definite operator. Let $\left\{e_{j}\right\}_{j \in \mathbf{N}}$ be an orthonormal basis for $H_{1}$ consisting of eigenfunctions of $W_{1}=\mathrm{APP}_{1}^{*} \mathrm{APP}_{1}$, ordered so that

$$
W_{1} e_{j}=\lambda_{j} e_{j}, \quad \text { for all } j \in \mathbf{N}
$$

with $\lambda_{1} \geq \lambda_{2} \geq \cdots>0$. Clearly, $\left\|W_{1}\right\|_{\operatorname{Lin}\left(H_{1}\right)}=\lambda_{1}$. Since $H_{1}$ is infinite-dimensional, the eigenvalues $\lambda_{i}$ are positive. Note that, for $f \in H_{1}$, we have

$$
\begin{aligned}
\|f\|_{L_{2}(I)}^{2} & =\langle f, f\rangle_{L_{2}(I)} \\
& =\left\langle\operatorname{APP}_{1} f, \mathrm{APP}_{1} f\right\rangle_{L_{2}(I)} \\
& =\left\langle f, W_{1} f\right\rangle_{H_{1}} \leq \lambda_{1}\|f\|_{H_{1}}^{2}
\end{aligned}
$$

Hence, assumption (5) holds if we assume that $\lambda_{1} \leq 1$. For simplicity, we also assume that $e_{1} \equiv 1 \in H_{1}$, with $\|1\|_{H_{1}}=1$, so that $\lambda_{1}=1$.
We now move on to the general case $d \geq 1$, defining the tensor product space $H_{d}=H_{1}^{\otimes d}$, which is a Hilbert space under the inner product
$\left\langle\bigotimes_{j=1}^{d} v_{j}, \bigotimes_{j=1}^{d} w_{j}\right\rangle_{H_{d}}=\prod_{j=1}^{d}\left\langle v_{j}, w_{j}\right\rangle_{H_{1}}$ for all $v_{1}, \ldots, v_{d}, w_{1}, \ldots, w_{d} \in H_{1}$,
where

$$
\left(\bigotimes_{j=1}^{d} v_{j}\right)(x)=\prod_{j=1}^{d} v_{j}\left(x_{j}\right), \quad \text { for all } x=\left(x_{1}, x_{2}, \ldots, x_{d}\right) \in I^{d}
$$

Let $\mathrm{APP}_{d}$ denote the canonical embedding of $H_{d}$ into $L_{2}\left(I^{d}\right)$ given by

$$
\mathrm{APP}_{d} v=v, \quad \text { for all } v \in H_{d}
$$

Clearly, $\left\|\mathrm{APP}_{d}\right\|=1$. Let $W_{d}=\mathrm{APP}_{d}^{*} \mathrm{APP}_{d}$. For a multi-index $\boldsymbol{\alpha} \in \mathbf{N}^{d}$, let

$$
e_{\boldsymbol{\alpha}}=\bigotimes_{j=1}^{d} e_{\alpha_{j}} \quad \text { and } \quad \lambda_{\boldsymbol{\alpha}}=\prod_{j=1}^{d} \lambda_{\alpha_{j}}
$$

Then

$$
W_{d} e_{\boldsymbol{\alpha}}=\lambda_{\boldsymbol{\alpha}} e_{\boldsymbol{\alpha}}, \quad \text { for all } \boldsymbol{\alpha} \in \mathbf{N}
$$

and

$$
\left\langle e_{\boldsymbol{\alpha}}, e_{\boldsymbol{\beta}}\right\rangle_{H_{d}}=\delta_{\boldsymbol{\alpha}, \boldsymbol{\beta}}, \quad \text { for all } \boldsymbol{\alpha}, \boldsymbol{\beta} \in \mathbf{N}^{d}
$$

Thus $\left\{e_{\boldsymbol{\alpha}}\right\}_{\boldsymbol{\alpha} \in \mathbf{N}^{d}}$ is an orthonormal system of eigenfunctions of $W_{d}$.
Knowing the eigensystem of $W_{d}$, we can determine the $n$th minimal error $e\left(n, \operatorname{APP}_{H_{d}}, \Lambda^{\text {all }}\right)$. Let

$$
\left\{\lambda_{d, j}\right\}_{j \in \mathbf{N}}=\left\{\lambda_{\boldsymbol{\alpha}}\right\}_{\boldsymbol{\alpha} \in \mathbf{N}^{d}}
$$

with

$$
\lambda_{d, 1} \geq \lambda_{d, 2} \geq \cdots>0
$$

and let $e_{d, j}$ be the eigenfunction corresponding to $\lambda_{d, j}$. It is well known (see, e.g., [16, subsection 4.5]) that

$$
e\left(n, \mathrm{APP}_{H_{d}}, \Lambda^{\text {all }}\right)=\sqrt{\lambda_{d, n+1}}
$$

this error being attained by the algorithm

$$
A_{n}(v)=\sum_{j=1}^{n}\left\langle v, e_{d, j}\right\rangle_{H_{d}} e_{d, j}
$$

We now let $F_{d}=H_{d}$ and $Q_{d}=H_{2 d}$. Then assumptions (5) and (10) hold and $1 \in B F_{d}$ with $\|1\|_{F_{d}}=\|1\|_{L_{2}\left(I^{d}\right)}=1$. What can we say about the tractability of the Fredholm problem?
If $\lambda_{2}=1$, then [10, Theorem 5.5] tells us that the $L_{2}$-approximation problem for $H_{d}$ is intractable for the class $\Lambda^{\text {all }}$ (and thus also for $\Lambda^{\text {std }}$ ). Hence, the Fredholm problem is also intractable for $\Lambda^{\text {all }}$ (and $\Lambda^{\text {std }}$ ) by Corollary 3.1.

We now suppose that $\lambda_{2} \in(0,1)$. In addition, for the remainder of this subsection, we shall restrict our attention to the case where some $p>0$ exists such that

$$
\lambda_{j}=\Theta\left(j^{-p}\right), \quad \text { as } j \rightarrow \infty
$$

From [10, Theorem 5.5], we find that the $L_{2}$-approximation problem for $H_{d}$ is not polynomially tractable for the class $\Lambda^{\text {all }}$ (and so for $\Lambda^{\text {std }}$ ). Again, using Corollary 3.1, we see that the Fredholm problem is also
not polynomially tractable for $\Lambda^{\text {all }}$ (and $\Lambda^{\text {std }}$ ). So let's see what we can say about quasi-polynomial tractability.
First, suppose that class $\Lambda^{\text {all }}$ is used. From [6, subsection 3.1], we find that the $L_{2}$-approximation problem for $H_{d}$ is quasi-polynomially tractable with

$$
t=\max \left\{\frac{2}{p}, \frac{2}{\ln \lambda_{2}^{-1}}\right\}
$$

Hence, Corollary 3.2 tells us that the Fredholm problem is also quasipolynomially tractable and

$$
n\left(\varepsilon, S_{d}, \Lambda_{d, 2 d}^{\text {all }}\right) \leq C \exp \left(t_{S}^{*}\left(1+\ln \varepsilon^{-1}\right)(1+\ln d)\right)
$$

with

$$
t_{S}^{*}=t \max \left\{1+\ln \frac{1}{1-M_{1}}, 1+\max \left\{0, \ln \frac{2 M_{1}}{\left(1-M_{1}\right)^{2}}\right\}(1+\ln 2)\right\} .
$$

Now suppose that we use the class $\Lambda^{\text {std }}$. Unfortunately, there are currently no general results for the case of standard information; we only know of some examples. From [6, subsection 3.2], we know that there is a piecewise-constant function space for which quasi-polynomial tractability is the same for $\Lambda^{\text {all }}$ and $\Lambda^{\text {std }}$, and there is a Korobov space for which quasi-polynomial tractability does not hold. So in the former case, the Fredholm problem will be quasi-polynomially tractable; in the latter case, it will not be quasi-polynomially tractable.
4.3. Results for a weighted Sobolev space. The results reported in subsection 4.2 tell us that if we want the Fredholm problem to be polynomially tractable, then the right-hand side and kernel must belong to non-isotropic spaces, in which different variables or groups of variables play different roles. In this subsection, we examine a particular weighted space $H_{d, m, \boldsymbol{\gamma}}$, where $m \in \mathbf{N}$ is a fixed positive integer that measures the smoothness of the space, and $\gamma$ is a sequence of weights that measure the importance of groups of variables. This will motivate the general definition presented in Section 5.

Our analysis uses the results and ideas found in [24]. We build our space $H_{d, m, \gamma}$ in stages, starting with an unweighted univariate
space $H_{1, m}$, then going to an unweighted multivariate space $H_{d, m}$, and finally arriving at our weighted multivariate space $H_{d, m, \gamma}$.

So we first look at case $d=1$. The space $H_{1, m}$ consists of real functions defined on $I$, whose $(m-1)$ st derivatives are absolutely continuous and whose $m$ th derivatives belong to $L_{2}(I)$, under the inner product

$$
\begin{aligned}
&\langle v, w\rangle_{H_{1, m}}=\int_{I} v(x) w(x) d x+\int_{I} v^{(m)}(x) w^{(m)}(x) d x \\
& \text { for all } v, w \in H_{1, m}
\end{aligned}
$$

For $d \in \mathbf{N}$, define $H_{d, m}=H_{1, m}^{\otimes d}$ as a $d$-fold tensor product of $H_{1, m}$, under the inner product

$$
\begin{aligned}
& \langle v, w\rangle_{H_{d, m}}=\int_{I^{d}} v(x) w(x) d x+\sum_{\substack{\mathfrak{u} \subseteq[d] \\
\mathfrak{u} \neq \varnothing}} \int_{I^{d}} \frac{\partial^{m|\mathfrak{u}|}}{\partial^{m} x_{\mathfrak{u}}} v(x) \frac{\partial^{m|\mathfrak{u}|}}{\partial^{m} x_{\mathfrak{u}}} w(x) d x \\
& \text { for all } v, w \in H_{d, m} \text {. }
\end{aligned}
$$

Here, $|\mathfrak{u}|$ denotes the size of $\mathfrak{u} \subseteq[d]:=\{1,2, \ldots, d\}$, and $x_{\mathfrak{u}}$ denotes the vector whose components are those components $x_{j}$ of $x$ for which $j \in \mathfrak{u}$.

We are now ready to define our weighted Sobolev space. Let

$$
\gamma=\left\{\gamma_{d, \mathfrak{u}}\right\}_{\mathfrak{u} \subseteq[d]}
$$

be a set of non-negative weights. For simplicity, we assume that $\gamma_{d, \varnothing}=1$. Then we let

$$
H_{d, m, \gamma}=\left\{v \in H_{d, m}: \gamma_{d, \mathfrak{u}}=0 \Longrightarrow \frac{\partial^{m|\mathfrak{u}|}}{\partial^{m} x_{\mathfrak{u}}} v \equiv 0\right\}
$$

under the inner product

$$
\begin{aligned}
\langle v, w\rangle_{H_{d, m, \boldsymbol{\gamma}}}= & \int_{I^{d}} v(x) w(x) d x \\
& +\sum_{\substack{\mathfrak{u} \subseteq[d] \\
\mathfrak{u} \neq \varnothing \\
\gamma_{d, u}>0}} \gamma_{d, \mathfrak{u}}{ }^{-1} \int_{I^{d}} \frac{\partial^{m|\mathfrak{u}|}}{\partial^{m} x_{\mathfrak{u}}} v(x) \frac{\partial^{m|\mathfrak{u}|}}{\partial^{m} x_{\mathfrak{u}}} w(x) d x \\
& \quad \text { for all } v, w \in H_{d, m, \gamma}
\end{aligned}
$$

Interpreting $0 / 0$ as 0 , we may rewrite this inner product in the simpler form

$$
\begin{align*}
&\langle v, w\rangle_{H_{d, m, \gamma}}=\sum_{\mathfrak{u} \subseteq[d]} \gamma_{d, \mathfrak{u}}{ }^{-1} \int_{I^{d}} \frac{\partial^{m|\mathfrak{u}|}}{\partial^{m} x_{\mathfrak{u}}} v(x) \frac{\partial^{m|\mathfrak{u}|}}{\partial^{m} x_{\mathfrak{u}}} w(x) d x  \tag{21}\\
& \quad \text { for all } v, w \in H_{d, m, \boldsymbol{\gamma}} .
\end{align*}
$$

Let $F_{d}=H_{d, m_{F}, \gamma_{F}}$ and $Q_{d}=H_{d, m_{Q}, \gamma_{Q}}$. Here, the weights $\gamma_{F}=$ $\left\{\gamma_{d, \mathfrak{u}, F}\right\}$ and $\gamma_{Q}=\left\{\gamma_{d, \mathfrak{u}, Q}\right\}$ may be different but we have $\gamma_{d . \varnothing, F}=$ $\gamma_{d, \varnothing, Q}=1$. Again, assumption (5) is satisfied; moreover, since $\|1\|_{F_{d}}=\|1\|_{L_{2}\left(I^{d}\right)}=1$, we have $1 \in B F_{d}$.
Recall that, if $Q=\left\{Q_{d}\right\}_{d \in \mathbf{N}}$ satisfies the extension property, then the Fredholm problem is no easier than the $L_{2}$-approximation problem for $Q_{d}$. So what does it take for $Q$ to satisfy the extension property? The key inequality (10) clearly depends on the weights. For instance, (10) holds whenever

$$
\gamma_{d, \mathfrak{u}, Q} \leq \gamma_{2 d, \mathfrak{u}, Q}, \quad \text { for all } d \in \mathbf{N}, \mathfrak{u} \subseteq[d]
$$

As a particularly simple case, this inequality holds when weights $\gamma_{d, \mathfrak{u}, Q}$ are independent of $d$, a case that has been well-studied in many papers that have dealt with tractability. So although we cannot say that there is no lack of generality in assuming that the extension property holds, it is certainly not an unwarranted assumption.

So let us assume that $Q$ satisfies the extension property. What can we say about the tractability of the Fredholm problem?

The first result is as follows:
If $m_{F}>1$ or $m_{Q}>1$, then the Fredholm problem is intractable for the class $\Lambda^{\text {all }}$ (and obviously also for $\Lambda^{\text {std }}$ ), no matter how the weights are chosen.
The reason for this is that the $L_{2}\left(I^{d}\right)$-approximation problem is intractable for $H_{d, m, \gamma}$ whenever $m>1$, see [24, Theorem 3.1]. This last result may seem somewhat counter-intuitive, since it tells us that increased smoothness (i.e., increasing $m$ ) is bad. The reason for this intractability is that $\|\cdot\|_{H_{d, m, \gamma}}=\|\cdot\|_{L_{2}\left(I^{d}\right)}$ on the $m^{d}$-dimensional space $\mathscr{P}_{d . m-1}$ of $d$-variate polynomials having degree at most $m-1$ in each variable, which implies that

$$
e\left(n, \mathrm{APP}_{H_{d, m}, r}, \Lambda_{d}\right)=1, \quad \text { for all } n<m^{d}
$$

and therefore

$$
n\left(\varepsilon, \operatorname{APP}_{H_{d, m}, \gamma}, \Lambda^{\text {all }}\right) \geq m^{d}, \quad \text { for all } \varepsilon \in(0,1)
$$

Thus, in the remainder of this subsection, we shall assume that $m_{F}=$ $m_{Q}=1$, so that

$$
F_{d}=H_{d, 1, \boldsymbol{\gamma}_{F}} \quad \text { and } \quad Q_{d}=H_{d, 1, \boldsymbol{\gamma}_{Q}}
$$

For simplicity, we only look at families $\gamma$ of bounded product weights, which have the form

$$
\gamma_{d, \mathfrak{u}, X}=\prod_{j \in \mathfrak{u}} \gamma_{d, j, X}, \quad \text { for all } \mathfrak{u} \subseteq[d]
$$

for a non-negative sequence

$$
\gamma_{d, 1, X} \geq \gamma_{d, 2, X} \geq \cdots \geq \gamma_{d, d, X}
$$

for any $d \in \mathbf{N}$. Here $X \in\{F, Q\}$, which indicates that we may use different weights for the space sequences $F=\left\{F_{d}\right\}_{d \in \mathbf{N}}$ and $Q=$ $\left\{Q_{d}\right\}_{d \in \mathbf{N}}$. The boundedness of these product weights means that

$$
M:=\sup _{d \in \mathbf{N}} \max \left\{\gamma_{d, 1, F}, \gamma_{d, 1, Q}\right\}<\infty
$$

It is easy to see that if

$$
\gamma_{d, j, Q} \leq \gamma_{2 d, j, Q}, \quad \text { for all } d \in \mathbf{N}, j \in[d]
$$

then $Q$ satisfies the extension property. In particular, this inequality holds when the weights $\gamma_{d, j}$ do not depend on $d$.
We first consider $\Lambda^{\text {all }}$. Since tractability results for the Fredholm problem are tied to those of the approximation problem, we will use the results found in [24].

- Strong polynomial tractability. We know that the problem $\mathrm{APP}_{F}$ is strongly polynomially tractable if and only if a positive number $\tau_{F}$ exists such that

$$
\begin{equation*}
\limsup _{d \rightarrow \infty} \sum_{j=1}^{d} \gamma_{d, j, F}^{\tau_{F}}<\infty \tag{22}
\end{equation*}
$$

Define $\tau_{F}^{*}$ to be the infimum of $\tau_{F}$ such that (22) holds. Then the strong exponent for $\mathrm{APP}_{F}$ is $\max \left\{1,2 \tau_{F}^{*}\right\}$. The situation for $\mathrm{APP}_{Q}$ is analogous. From Corollaries 3.1 and 3.2 , we see that the Fredholm problem $S$ is strongly polynomially tractable if and only if both (22) and its analog (with $F$ replaced by $Q$ ) hold, in which case the strong exponent for the Fredholm problem is $\max \left\{1,2 \tau_{F}^{*}, 2 \tau_{Q}^{*}\right\}$.

- Polynomial tractability. The problem $\mathrm{APP}_{F}$ is polynomially tractable if and only if a positive number $\tau_{F}$ exists such that

$$
\begin{equation*}
\limsup _{d \rightarrow \infty} \frac{1}{\ln d} \sum_{j=1}^{d} \gamma_{d, j, F}^{\tau_{F}}<\infty \tag{23}
\end{equation*}
$$

The situation for $\mathrm{APP}_{Q}$ is analogous. From Corollaries 3.1 and 3.2, we see that Fredholm problem $S$ is polynomially tractable if and only if both (23) and its analog (with $F$ replaced by $Q$ ) hold.

- Quasi-polynomial tractability. If we replace all $\gamma_{d, j, F}$ and $\gamma_{d, j, G}$ by their upper bound $M$, then the approximation problem becomes harder. The latter approximation problem is unweighted with the univariate eigenvalues $\lambda_{1}=1>\lambda_{2}$ and $\lambda_{j}=\mathcal{O}\left(j^{-2}\right)$. Therefore, it is quasi-polynomially tractable (see subsection 4.2). This implies that the weighted case is quasi-polynomially tractable for any bounded product weights. Therefore, the Fredholm is also quasi-polynomially tractable.
- Weak tractability. Since the Fredholm problem is quasi-polynomially tractable, it is also weakly tractable.

We now turn to the case of standard information $\Lambda^{\text {std }}$. We will use the results found in $[\mathbf{2 4}]$ for polynomial tractability for the approximation problem, upon which we will base the polynomial tractability results for the Fredholm problem.

- Strong polynomial tractability. The problem $\mathrm{APP}_{F}$ is strongly polynomially tractable if and only if

$$
\begin{equation*}
\limsup _{d \rightarrow \infty} \sum_{j=1}^{d} \gamma_{d, j, F}<\infty \tag{24}
\end{equation*}
$$

The situation for $\mathrm{APP}_{Q}$ is analogous. From Corollaries 3.1 and 3.2, we see that Fredholm problem $S$ is strongly polynomially tractable if and only if both ((24) and its analog (with $F$ replaced by $Q$ ) hold.

When this holds, the strong exponents for all three problems lie in interval $[1,4]$.

- Polynomial tractability. The problem $\mathrm{APP}_{F}$ is polynomially tractable if and only if

$$
\begin{equation*}
\limsup _{d \rightarrow \infty} \frac{1}{\ln d} \sum_{j=1}^{d} \gamma_{d, j, F}<\infty \tag{25}
\end{equation*}
$$

The situation for $\mathrm{APP}_{Q}$ is analogous. From Corollaries 3.1 and 3.2, we see that Fredholm problem $S$ is polynomially tractable if and only if both (25) and its analog (with $F$ replaced by $Q$ ) hold.
At this time, we do not have conditions that are necessary and sufficient for the approximation problem to be quasi-polynomially tractable or weakly tractable for standard information. This means that the same is true for the Fredholm problem.
5. Weighted tensor product spaces. In subsection 4.2, we saw that the Fredholm problem is not polynomially tractable if either $F_{d}$ or $Q_{2 d}$ is from a family of unweighted tensor product spaces. However in subsection 4.3, we saw that our problem can be polynomially tractable (or even strongly polynomially tractable) if both $F_{d}$ and $Q_{2 d}$ are from families of weighted Sobolev spaces. This leads us to wonder whether replacing the unweighted tensor product spaces of subsection 4.2 by weighted tensor product spaces can render the Fredholm problem polynomially tractable, or maybe even strongly polynomially tractable.

So with spaces $H_{d, m, \gamma}$ as a guide, we now give the general definition of a weighted tensor product space, which captures this idea that different variables or groups of variables can play different roles. In Section 6, we will study a modified interpolatory algorithm for the Fredholm problem, and our analysis of this algorithm will draw heavily on the properties of weighted tensor product spaces.

Our presentation is based on that found in [10, subsection 5.3], which should be consulted for additional details.

Let $\left\{\gamma_{d, \mathfrak{u}}\right\}_{\mathfrak{u} \subseteq[d]}$ be a set of non-negative weights. We assume the following about these weights:

- $\gamma_{d, \varnothing}=1$, and
- $\gamma_{d, \mathfrak{u}} \leq 1$ for all $\mathfrak{u} \subseteq[d]$.
- There is at least one nonempty $\mathfrak{u} \subseteq[d]$ for which $\gamma_{d, \mathfrak{u}}>0$.

Let $H_{1}$ be defined as in subsection 4.2. That is, $H_{1}$ is an infinite dimensional space with $e_{1} \equiv 1 \in H_{1}$ and $\left\|e_{1}\right\|_{H_{1}}=1$. Let

$$
\widetilde{H}_{1}=\left\{f \in H_{1}:\left\langle f, e_{1}\right\rangle_{H_{1}}=0\right\}
$$

be the subspace of $H_{1}$ of functions orthogonal to $e_{1} \equiv 1$. We now define

$$
\begin{equation*}
H_{d, \boldsymbol{\gamma}}=\bigoplus_{\mathfrak{u} \subseteq[d]} \widetilde{H}_{1, \mathfrak{u}} \tag{26}
\end{equation*}
$$

where $\widetilde{H}_{1, \mathfrak{u}}=\widetilde{H}_{1}^{\otimes|\mathfrak{u}|}$ is the $|\mathfrak{u}|$-fold tensor product of $\widetilde{H}_{1}$. That is, $v \in H_{d, \gamma}$ has the unique decomposition

$$
\begin{equation*}
v(x)=\sum_{\mathfrak{u} \subseteq[d]} v_{\mathfrak{u}}\left(x_{\mathfrak{u}}\right), \quad \text { for all } x \in I^{d}, \tag{27}
\end{equation*}
$$

where

$$
v_{\mathfrak{u}} \in \widetilde{H}_{1, \mathfrak{u}}, \quad \text { for all } \mathfrak{u} \subseteq[d] .
$$

Although $H_{d, \gamma}$ can algebraically be identified with a subspace of the space $H_{d}$ described in subsection 4.2, the spaces $H_{d}$ and $H_{d, \gamma}$ generally have different topologies. The inner product for $H_{d, \gamma}$ is given by

$$
\begin{equation*}
\langle v, w\rangle_{H_{d, \gamma}}=\sum_{\mathfrak{u} \subseteq[d]} \gamma_{d, \mathfrak{u}}{ }^{-1}\left\langle v_{\mathfrak{u}}, w_{\mathfrak{u}}\right\rangle_{H_{d}}, \quad \text { for all } v, w \in H_{d, \boldsymbol{\gamma}} \tag{28}
\end{equation*}
$$

For this to be well-defined, we assume that $v_{\mathfrak{u}}=w_{\mathfrak{u}}=0$ whenever $\gamma_{d, \mathfrak{u}}=0$, interpreting $0 / 0$ as 0 . (Compare with (21) in subsection 4.3.) The decomposition (27) tells us that we write $v$ as a sum of mutually orthogonal functions, each term $v_{\mathfrak{u}}$ depending only upon the variables in $\mathfrak{u}$. Formula (28) tells us that the contribution made by $\left\|v_{\mathfrak{u}}\right\|_{H_{d}}$ to $\|v\|_{H_{d, \gamma}}$ is moderated by the weight $\gamma_{d, \mathfrak{u}}$.

Let

$$
e_{\boldsymbol{\alpha}}(x)=\prod_{k=1}^{d} e_{\alpha_{k}}\left(x_{k}\right), \quad \text { for all } x=\left(x_{1}, x_{2}, \ldots, x_{d}\right) \in I^{d}
$$

for any multi-index $\boldsymbol{\alpha}=\left[\alpha_{1}, \alpha_{2}, \ldots, \alpha_{d}\right] \in \mathbf{N}^{d}$. Note that, if $\alpha_{k}=1$, then $e_{\alpha_{k}} \equiv 1$, and so $e_{\boldsymbol{\alpha}}$ does not depend upon $x_{k}$. Defining

$$
\mathfrak{u}(\boldsymbol{\alpha})=\left\{k \in[d]: \alpha_{k} \geq 2\right\}
$$

we may write

$$
e_{\boldsymbol{\alpha}}(x)=\prod_{k \in \mathfrak{u}(\boldsymbol{\alpha})} e_{\alpha_{k}}\left(x_{k}\right), \quad \text { for all } x=\left(x_{1}, x_{2}, \ldots, x_{d}\right) \in I^{d}
$$

For further details, once again see [10, subsection 5.3].
Let $W_{d, \gamma}=\mathrm{APP}_{H_{d, \gamma}}^{*} \mathrm{APP}_{H_{d, \gamma}}$. Defining

$$
e_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}}=\gamma_{d, \mathfrak{u}(\boldsymbol{\alpha})}^{1 / 2} e_{\boldsymbol{\alpha}}, \quad \text { for all } \boldsymbol{\alpha} \in \mathbf{N}^{d}
$$

we see that $\left\{e_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}}\right\}_{\boldsymbol{\alpha} \in \mathbf{N}^{d}}$ is an orthonormal basis of $H_{d, \boldsymbol{\gamma}}$, consisting of eigenfunctions of $W_{d, \gamma}$, with

$$
W_{d, \boldsymbol{\gamma}} e_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}}=\lambda_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}} e_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}} \quad \text { for all } \boldsymbol{\alpha} \in \mathbf{N}^{d}
$$

where

$$
\lambda_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}}=\gamma_{d, \mathfrak{u}(\boldsymbol{\alpha})} \prod_{k=1}^{d} \lambda_{\alpha_{k}}, \quad \text { for all } \boldsymbol{\alpha} \in \mathbf{N}^{d}
$$

Note that all eigenvalues $\lambda_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}} \in[0,1]$ since we assumed that all $\gamma_{d, \mathfrak{u}} \leq 1$ and all $\lambda_{j} \leq 1$. Furthermore, infinitely many $\lambda_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}}$ are positive. Indeed, since a nonempty $\mathfrak{u}$ exists for which $\gamma_{d, \mathfrak{u}}>0$, it is enough to take indices $\boldsymbol{\alpha}$ such that $\mathfrak{u}(\boldsymbol{\alpha})=\mathfrak{u}$; since $\lambda_{\boldsymbol{\alpha}_{k}}>0$ for $k \in[d]$, all the $\lambda_{\boldsymbol{\alpha}, d, \boldsymbol{\gamma}}$ are positive. The condition $\mathfrak{u}(\boldsymbol{\alpha})=\mathfrak{u}$ holds if $\alpha_{k} \geq 2$ for $k \in \mathfrak{u}$, and $\alpha_{k}=1$ for $k \notin \mathfrak{u}$. For a nonempty $\mathfrak{u}$, we have infinitely many such indices $\boldsymbol{\alpha}$, and therefore, we have infinitely many positive eigenvalues, as claimed.

In what follows, it will be useful to order the eigenvalues of $W_{d, \gamma}$ in non-increasing order. So we order the multi-indices in $\mathbf{N}^{d}$ as $\boldsymbol{\alpha}[1], \boldsymbol{\alpha}[2], \ldots$, with

$$
\begin{equation*}
1=\lambda_{\boldsymbol{\alpha}[1], d, \boldsymbol{\gamma}} \geq \lambda_{\boldsymbol{\alpha}[2], d, \boldsymbol{\gamma}} \geq \cdots>0 \tag{29}
\end{equation*}
$$

We stress the last inequality in (29) which holds since infinitely many eigenvalues are positive. This also implies that $\gamma_{d, \mathfrak{u}(\boldsymbol{\alpha}[j])}>0$.

It will often be useful to write $\lambda_{j, d, \boldsymbol{\gamma}}$ and $e_{j, d, \boldsymbol{\gamma}}$, rather than $\lambda_{\boldsymbol{\alpha}[j], d, \boldsymbol{\gamma}}$ and $e_{\boldsymbol{\alpha}[j], d, \boldsymbol{\gamma}}$, so that

$$
W_{d, \boldsymbol{\gamma}} e_{j, d, \boldsymbol{\gamma}}=\lambda_{j, d, \boldsymbol{\gamma}} e_{j, d, \boldsymbol{\gamma}}
$$

with

$$
1=\lambda_{1, d, \gamma} \geq \lambda_{2, d, \gamma} \geq \cdots>0
$$

We shall do so when this causes no confusion.

Remark. A sequence of weighted tensor product spaces $\left\{H_{d, \gamma}\right\}_{d=1,2, \ldots}$ defined in this section has the extension property if

$$
\gamma_{d, \mathfrak{u}} \leq \gamma_{2 d, \mathfrak{u}}, \quad \text { for all } d \in \mathbf{N}, \mathfrak{u} \subseteq[d]
$$

For tensor product spaces, the eigenfunctions $e_{j, 2 d, \gamma}$ of $W_{2 d, \gamma_{Q}}$ are related to the eigenfunctions $e_{j, d, \boldsymbol{\gamma}}$ of $W_{d, \boldsymbol{\gamma}_{Q}}$. Indeed, the eigenfunctions of $W_{2 d, \gamma_{Q}}$ have the form

$$
e_{j, 2 d, \boldsymbol{\gamma}_{Q}}=e_{\boldsymbol{\alpha}[j], 2 d, \boldsymbol{\gamma}_{Q}}=\gamma_{2 d, \mathfrak{u}(\boldsymbol{\alpha}[j]), Q}^{1 / 2} e_{\boldsymbol{\alpha}[j]},
$$

where

$$
\boldsymbol{\alpha}[j]=\left[(\alpha[j])_{1},(\alpha[j])_{2}, \ldots,(\alpha[j])_{2 d}\right] \in \mathbf{N}^{2 d}
$$

has $2 d$ components. Let

$$
\boldsymbol{\alpha}_{1}[j]=\left[(\alpha[j])_{1},(\alpha[j])_{2}, \ldots,(\alpha[j])_{d}\right] \in \mathbf{N}^{d}
$$

and

$$
\boldsymbol{\alpha}_{2}[j]=\left[(\alpha[j])_{d+1},(\alpha[j])_{d+2}, \ldots,(\alpha[j])_{2 d}\right] \in \mathbf{N}^{d}
$$

Since $e_{\boldsymbol{\alpha}[j]}=e_{\boldsymbol{\alpha}_{1}[j]} \otimes e_{\boldsymbol{\alpha}_{1}[j]}$, we obtain

$$
\begin{aligned}
& e_{\boldsymbol{\alpha}[j], 2 d, \boldsymbol{\gamma}}=\gamma_{2 d, \mathfrak{u}(\boldsymbol{\alpha}[j])}^{1 / 2} e_{\boldsymbol{\alpha}_{1}[j]} \otimes e_{\boldsymbol{\alpha}_{2}[j]}, \\
& e_{\boldsymbol{\alpha}[j], 2 d, \boldsymbol{\gamma}}=\frac{\gamma_{2 d, \mathfrak{u}(\boldsymbol{\alpha}[j])}^{1 / 2}}{\gamma_{d, \mathfrak{u}\left(\boldsymbol{\alpha}_{1}[j]\right)}^{1 / 2} \gamma_{d, \mathfrak{u}\left(\boldsymbol{\alpha}_{2}[j]\right)}^{1 / 2}} e_{\boldsymbol{\alpha}_{1}[j], d, \boldsymbol{\gamma}} \otimes e_{\boldsymbol{\alpha}_{2}[j], d, \boldsymbol{\gamma}} .
\end{aligned}
$$

Remark. The fact that weights could sometimes help us vanquish the curse of dimensionality for Sobolev spaces is what led us to think about using weighted tensor product spaces for this problem. So it's somewhat ironic that weighted Sobolev spaces are not weighted tensor product spaces. A full discussion is given in [10, subsection 5.4.2]; the basic idea is that if we were to define an operator $W_{d, \boldsymbol{\gamma}, \text { Sob }}$ for weighted Sobolev spaces that is analogous to the operator $W_{d, \gamma}$ defined in this section, we would find that the eigenvalues of $W_{d, \boldsymbol{\gamma}, \text { Sob }}$ are not of the same form as the eigenvalues of $W_{d, \boldsymbol{\gamma}}$.
6. Interpolatory algorithm for weighted tensor product spaces. We now define an interpolatory algorithm whose error for the Fredholm problem will be expressed in terms of the $L_{2}$-approximation errors for $F_{d}$ and $Q_{d}$ as in Lemma 3.1. Then we analyze the implementation cost of this algorithm. As we shall see, the implementation cost will be quite small as long as we use tensor product spaces for $F_{d}$ and $Q_{d}$.

We first specify the spaces as $F_{d}=H_{d, \boldsymbol{\gamma}_{F}}$ and $Q_{d}=H_{d, \boldsymbol{\gamma}_{Q}}$, where $H_{d, \boldsymbol{\gamma}}$ is defined as in Section 5. This means that $\gamma_{F}=\left\{\gamma_{d, \mathfrak{u}, F}\right\}$ and $\gamma_{Q}=\left\{\gamma_{d, \mathfrak{u}, Q}\right\}$ are sequences of weights for the spaces $H_{d, \boldsymbol{\gamma}_{F}}$ and $H_{d, \boldsymbol{\gamma}_{Q}}$ satisfying the assumptions of Section 5. Note that the weight sequences $\gamma_{F}$ and $\gamma_{Q}$ may be different, or they may be the same. Thus, $\left\{e_{j, d, \gamma_{F}}\right\}_{j \in \mathbf{N}}$ is an $F_{d}$-orthonormal system, consisting of the eigenfunctions for $W_{d, \gamma_{F}}$, and $\left\{e_{j, 2 d, \gamma_{Q}}\right\}_{j \in \mathbf{N}}$ is a $Q_{2 d}$-orthonormal system, consisting of the eigenfunctions for $W_{2 d, \gamma_{Q}}$. In both cases, the corresponding eigenvalues $\lambda_{j, d, \boldsymbol{\gamma}_{F}}$ and $\lambda_{j, 2 d, \boldsymbol{\gamma}_{Q}}$ are ordered.
Let $n(F)$ and $n(Q)$ be two positive integers. The information about $f$ will be given as the first $n(F)$ inner products with respect to $\left\{e_{j, d, \gamma_{F}}\right\}_{j \in \mathbf{N}}$, and the information about $q$ as the first $n(Q)$ inner products with respect to $\left\{e_{j, 2 d, \gamma_{Q}}\right\}_{j \in \mathbf{N}}$. That is, we use the class $\Lambda^{\text {all }}$, and for $(f, q) \in B F_{d} \times Q_{2 d}^{\text {res }}$ we compute

$$
\begin{aligned}
& N_{n(F)}(f)=\left[\left\langle f, e_{1, d, \boldsymbol{\gamma}_{F}}\right\rangle_{H_{d, \boldsymbol{\gamma}_{F}}},\left\langle f, e_{2, d, \boldsymbol{\gamma}_{F}}\right\rangle_{H_{d, \boldsymbol{\gamma}_{F}}}, \ldots,\right. \\
& \left.\left\langle f, e_{n(F), d, \boldsymbol{\gamma}_{F}}\right\rangle_{H_{d, \boldsymbol{\gamma}_{F}}}\right]^{\top} \\
& N_{n(Q)}(q)=\left[\left\langle q, e_{1,2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \boldsymbol{\gamma}_{Q}}},\left\langle q, e_{2,2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \boldsymbol{\gamma}_{Q}}}, \ldots,\right. \\
& \left.\left\langle q, e_{n(Q), 2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \gamma_{Q}}}\right]^{\top} .
\end{aligned}
$$

Define the orthogonal projection operators

$$
P_{n(F), d, \boldsymbol{\gamma}_{F}}=\sum_{j=1}^{n(F)}\left\langle\cdot, e_{j, d, \boldsymbol{\gamma}_{F}}\right\rangle_{H_{d, \gamma_{F}}} e_{j, d, \boldsymbol{\gamma}_{F}}
$$

and

$$
P_{n(Q), 2 d, \boldsymbol{\gamma}_{Q}}=\sum_{j=1}^{n(Q)}\left\langle\cdot, e_{j, 2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \gamma_{Q}}} e_{j, 2 d, \boldsymbol{\gamma}_{Q}} .
$$

Knowing $N_{n(F)}(f)$ and $N_{n(Q)}(q)$, we know

$$
\tilde{f}=P_{n(F), d, \gamma_{F}} f \quad \text { and } \quad \widetilde{q}=P_{n(Q), 2 d, \gamma_{Q}} q
$$

Observe that $(\tilde{f}, \widetilde{q}) \in B F_{d} \times Q_{2 d}^{\mathrm{res}}$. Furthermore, $(\tilde{f}, \widetilde{q})$ interpolate the data, i.e.,

$$
N_{n(F)}(\widetilde{f})=N_{n(F)}(f) \quad \text { and } \quad N_{n(Q)}(\widetilde{q})=N_{n(Q)}(q)
$$

We define the interpolatory algorithm

$$
A_{n(F), n(Q)}^{\mathrm{INT}}(f, q)=S_{d}(\widetilde{f}, \widetilde{q}) \quad \text { for all } q(f, q) \in B F_{d} \times Q_{2 d}^{\mathrm{res}}
$$

as the exact solution of the Fredholm problem for $(\widetilde{f}, \widetilde{q})$. Lemma 3.1 gives an error bound for $A_{n(F), n(Q)}^{\mathrm{INT}}$ in terms of the errors of the $L_{2}$ approximation problems for $F_{d}$ and $Q_{2 d}$. As in the proof of Proposition 3.3, we can choose $n(F)$ and $n(Q)$ to make the approximation errors for $F_{d}$ and $Q_{2 d}$ be at most $\left(1-M_{1}\right) \varepsilon / 2$ and $\left(1-M_{1}\right)^{2} \varepsilon /\left(2 M_{1}\right)$, respectively; this guarantees that the error of $A_{n(F), n(Q)}^{\mathrm{INT}}$ for the Fredholm problem is at most $\varepsilon$.

Our next step is to reduce the computation of $\widetilde{u}=A_{n(F), n(Q)}^{\mathrm{INT}}(f, q)$ to the solution of a linear system of equations. To do this, we will use the notation and results of Section 5, suitably modified to take account of the fact that we are dealing with two sequences of weights. Now $\alpha_{F}[j]$ is the $d$-component multi-index giving the $j$ th-largest eigenvalue of $W_{d, \gamma_{F}}$ and $\alpha_{Q}[j]$ is the $2 d$-component multi-index giving the $j$ thlargest eigenvalue of $W_{2 d, \gamma_{Q}}$. Thus,

$$
e_{j, d, \boldsymbol{\gamma}_{F}}=e_{\boldsymbol{\alpha}_{F}[j], d, \boldsymbol{\gamma}_{F}}=\gamma_{d, \mathfrak{u}\left(\boldsymbol{\alpha}_{F}[j]\right), F}^{1 / 2} e_{\boldsymbol{\alpha}_{F}[j]}
$$

and

$$
e_{j, 2 d, \boldsymbol{\gamma}_{Q}}=e_{\boldsymbol{\alpha}_{Q}[j], 2 d, \boldsymbol{\gamma}_{Q}}=\gamma_{2 d, \mathfrak{u}\left(\boldsymbol{\alpha}_{Q}[j]\right), Q}^{1 / 2} e_{\boldsymbol{\alpha}_{1, Q}[j]} \otimes e_{\boldsymbol{\alpha}_{2, Q}[j]}
$$

Here, $\boldsymbol{\alpha}_{1, Q}[j]$ denotes the first $d$ indices of $\boldsymbol{\alpha}_{Q}[j]$, and $\boldsymbol{\alpha}_{2, Q}[j]$ denotes the remaining indices of $\boldsymbol{\alpha}_{Q}[j]$, as at the end of Section 5 .

We have

$$
\left\langle e_{\boldsymbol{\alpha}}, e_{\boldsymbol{\beta}}\right\rangle_{H_{d}}=\delta_{\boldsymbol{\alpha}, \boldsymbol{\beta}} \quad \text { and } \quad\left\langle e_{\boldsymbol{\alpha}}, e_{\boldsymbol{\beta}}\right\rangle_{L_{2}\left(I^{d}\right)}=\delta_{\boldsymbol{\alpha}, \boldsymbol{\beta}} \lambda_{\boldsymbol{\alpha}}
$$

and so the functions $\left\{e_{\boldsymbol{\alpha}}\right\}_{\boldsymbol{\alpha} \in \mathbf{N}^{d}}$ are orthogonal in the unweighted space $H_{d}$, as well as in the space $L_{2}\left(I^{d}\right)$. Since $A_{n(F), n(Q)}^{\mathrm{INT}}$ is an interpolatory algorithm, we see that $\widetilde{u}$ satisfies the equation

$$
\widetilde{u}=\int_{I^{d}} \widetilde{q}(\cdot, y) \widetilde{u}(y) d y+\widetilde{f}
$$

which can be rewritten as

$$
\begin{equation*}
\widetilde{u}=\sum_{j=1}^{n(Q)} \zeta_{j}\left\langle e_{\boldsymbol{\alpha}_{2, Q}[j]}, \widetilde{u}\right\rangle_{L_{2}\left(I^{d}\right)} e_{\boldsymbol{\alpha}_{1, Q}[j]}+\sum_{j=1}^{n(F)} \theta_{j} e_{\boldsymbol{\alpha}_{F}[j]} \tag{30}
\end{equation*}
$$

with

$$
\zeta_{j}=\left\langle q, e_{j, 2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \boldsymbol{\gamma}_{Q}}} \gamma_{2 d, \mathfrak{u}\left(\boldsymbol{\alpha}_{Q}[j]\right), Q}^{1 / 2}
$$

and

$$
\theta_{j}=\left\langle f, e_{j, d, \boldsymbol{\gamma}_{F}}\right\rangle_{H_{d, \boldsymbol{\gamma}_{F}}} \gamma_{d, \mathfrak{u}\left(\boldsymbol{\alpha}_{F}[j]\right), F}^{1 / 2}
$$

This proves that

$$
\begin{aligned}
\widetilde{u} \in E_{n(F), n(Q)}=\operatorname{span}\left\{e_{\boldsymbol{\alpha}_{F}[1]},\right. & e_{\boldsymbol{\alpha}_{F}[2]}, \ldots,
\end{aligned} e_{\boldsymbol{\alpha}_{F}[n(F)]}, e_{\boldsymbol{\alpha}_{1, Q}[1]}, ~\left(e_{\boldsymbol{\alpha}_{1, Q}[2]}, \ldots, e_{\left.\boldsymbol{\alpha}_{1, Q}[n(Q)]\right\}} .\right.
$$

Note that the elements $e_{\alpha_{F}[j]}$ are orthogonal for $j=1,2, \ldots, n(F)$. Moreover, the elements $e_{\alpha_{1, Q}[j]}$ are orthogonal for different $\alpha_{1, Q}[j]$. However, two kinds of "overlap" are possible:

- We might have $\boldsymbol{\alpha}_{F}[j]=\boldsymbol{\alpha}_{1, Q}\left[j^{\prime}\right]$ for some $j \in\{1,2, \ldots, n(F)\}$ and $j^{\prime} \in\{1,2, \ldots, n(Q)\}$.
- We might have $\boldsymbol{\alpha}_{1, Q}[j]=\boldsymbol{\alpha}_{1, Q}\left[j^{\prime}\right]$ for some $j, j^{\prime} \in\{1,2, \ldots, n(F)\}$. Therefore,

$$
m:=\operatorname{dim} E_{n(F), n(Q)} \in\{n(F), n(F)+1, \ldots, n(F)+n(Q)\}
$$

We remove all redundant $e_{\boldsymbol{\alpha}_{1, Q}[j]}$, as well as all $e_{\boldsymbol{\alpha}_{1, Q}[j]}$ that belong to span $\left\{e_{\boldsymbol{\alpha}_{F}[1]}, e_{\boldsymbol{\alpha}_{F}[2]}, \ldots, e_{\boldsymbol{\alpha}_{F}[n(F)]}\right\}$, calling the remaining elements $e_{\boldsymbol{\alpha}_{1, Q}\left[l_{1}\right]}, e_{\boldsymbol{\alpha}_{1, Q}\left[l_{2}\right]}, \ldots, e_{\boldsymbol{\alpha}_{1, Q}\left[l_{m-n(F)}\right]}$. Therefore,

$$
E_{n(F), n(Q)}=\operatorname{span}\left\{z_{1}, z_{2}, \ldots, z_{m}\right\},
$$

where

$$
z_{j}= \begin{cases}e_{\boldsymbol{\alpha}_{F}[j]} & \text { for } j \in\{1,2, \ldots, n(F)\} \\ e_{\boldsymbol{\alpha}_{1, Q}\left[l_{j-n(F)}\right]} & \text { for } j \in\{n(F)+1, n(F)+2, \ldots, m\}\end{cases}
$$

The elements $z_{1}, \ldots, z_{m}$ are $L_{2}\left(I^{d}\right)$-orthogonal, i.e., $\left\langle z_{j}, z_{k}\right\rangle_{L_{2}\left(I^{d}\right)}=0$ for $j \neq k$, with

$$
\left\|z_{j}\right\|_{L_{2}\left(I^{d}\right)}= \begin{cases}\lambda_{\boldsymbol{\alpha}_{F}[j], d, \boldsymbol{\gamma}_{F}}^{1 / 2} & \text { for } j \in\{1,2, \ldots, n(F)\} \\ \lambda_{\boldsymbol{\alpha}_{1, Q}\left[l_{j}-n(F)\right], d, \boldsymbol{\gamma}_{Q}}^{1 / 2} & \text { for } j \in\{n(F)+1, n(F)+2, \ldots, m\}\end{cases}
$$

We know that

$$
\widetilde{u}=\sum_{k=1}^{m} v_{k} z_{k}
$$

for some real coefficients $v_{1}, v_{2}, \ldots, v_{m}$. From (30), we conclude that

$$
\widetilde{u}=\sum_{k=1}^{m} v_{k}\left(\sum_{j=1}^{n(Q)} \zeta_{j}\left\langle e_{\boldsymbol{\alpha}_{2, Q}[j]}, z_{k}\right\rangle_{L_{2}\left(I^{d}\right)} e_{\boldsymbol{\alpha}_{1, Q}[j]}\right)+\sum_{j=1}^{n(F)} \theta_{j} e_{\boldsymbol{\alpha}_{F}[j]} .
$$

This leads to the system

$$
\begin{equation*}
(\mathbf{I}-\mathbf{K}) \mathbf{u}=\mathbf{b} \tag{31}
\end{equation*}
$$

of linear equations, where $\mathbf{I}$ denotes the $m \times m$ identity matrix, and the $m \times m$ matrix $\mathbf{K}=\left[\kappa_{i, k}\right]_{1 \leq i, k \leq m}$ is given by

$$
\kappa_{i, k}=\sum_{j=1}^{n(Q)} \zeta_{j} \frac{\left\langle e_{\boldsymbol{\alpha}_{2, Q}[j]}, z_{k}\right\rangle_{L_{2}\left(I^{d}\right)}\left\langle e_{\boldsymbol{\alpha}_{1, Q}[j]}, z_{i}\right\rangle_{L_{2}\left(I^{d}\right)}}{\left\langle z_{i}, z_{i}\right\rangle_{L_{2}\left(I^{d}\right)}},
$$

with

$$
\begin{aligned}
\mathbf{b} & =\left[\frac{\theta_{1}}{\left\langle z_{1}, z_{1}\right\rangle_{L_{2}\left(I^{d}\right)}}, \frac{\theta_{2}}{\left\langle z_{2}, z_{2}\right\rangle_{L_{2}\left(I^{d}\right)}}, \ldots, \frac{\theta_{n(F)}}{\left\langle z_{n(F)}, z_{n(F)}\right\rangle_{L_{2}\left(I^{d}\right)}}, 0,0, \ldots, 0\right]^{\top} \\
& \in \mathbf{R}^{m}
\end{aligned}
$$

and
$\mathbf{u}=\left[v_{1}, v_{2}, \ldots, v_{n(F)}, v_{n(F)+1}, \ldots, v_{m}\right]^{\top} \in \mathbf{R}^{m}$.

We can now look at some important properties of $\mathbf{K}$, including the structure of $\mathbf{K}$ and the invertibility of $\mathbf{I}-\mathbf{K}$.

Lemma 6.1. Define

$$
\mathscr{I}=\left\{\boldsymbol{\alpha}_{Q}[j]=\left(\boldsymbol{\alpha}_{1, Q}[j], \boldsymbol{\alpha}_{2, Q}[j]\right) \in \mathbf{N}^{2 d}: 1 \leq j \leq n(Q)\right\} .
$$

1. We have

$$
\kappa_{i, k}= \begin{cases}\zeta_{j} \lambda_{\boldsymbol{\alpha}_{2, Q}[j]} & \text { if }(i, k)=\left(\boldsymbol{\alpha}_{1, Q}[j], \boldsymbol{\alpha}_{2, Q}[j]\right) \\ & \text { for some } j \in\{1,2, \ldots, n(Q)\} \\ 0 & \text { if }(i, k) \notin \mathscr{I},\end{cases}
$$

and so the matrix $\mathbf{K}$ has at most $n(Q)$ non-zero elements.
2. $\|\mathbf{K}\|_{\operatorname{Lin}\left[\ell_{2}\left(\mathbf{R}^{m}\right)\right]} \leq M_{1}<1$.
3. The matrix $\mathbf{I}-\mathbf{K}$ is invertible, with

$$
\left\|(\mathbf{I}-\mathbf{K})^{-1}\right\|_{\operatorname{Lin}\left[\ell_{2}\left(\mathbf{R}^{m}\right)\right]} \leq \frac{1}{1-M_{1}}
$$

Proof. For part 1, note that the coefficient $\kappa_{i, k}$ may be nonzero only if an integer $j \in[1, n(Q)]$ exists such that

$$
z_{i}=e_{\boldsymbol{\alpha}_{1, Q}[j]} \quad \text { and } \quad z_{k}=e_{\boldsymbol{\alpha}_{2, Q}[j]},
$$

that is, when $(i, k) \in \mathscr{I}$. In this case, there is at most one nonzero term in the sum defining $\kappa_{i, k}$, since $\mathscr{I}$ consists of distinct elements. Then

$$
\begin{aligned}
\kappa_{i, k} & =\zeta_{j}\left\|e_{\boldsymbol{\alpha}_{2, Q}[j]}\right\|_{L_{2}\left(I^{d}\right)}^{2} \\
& =\zeta_{j} \lambda_{\boldsymbol{\alpha}_{2, Q}[j]} \\
& =\left\langle q, e_{j, 2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \boldsymbol{\gamma}_{Q}}} \gamma_{2 d, \mathfrak{u}\left(\boldsymbol{\alpha}_{Q}[j]\right), Q}^{1 / 2} \lambda_{\boldsymbol{\alpha}_{2, Q}[j]}
\end{aligned}
$$

Obviously, if $(i, k) \notin \mathscr{I}$ then $\kappa_{i, k}=0$. Hence, the number of nonzero coefficients of the matrix $\mathbf{K}$ is at most $\mid \mathscr{I}=n(Q)$, as claimed in part 1 .

To see that part 2 holds, we estimate $\|\mathbf{K}\|_{\operatorname{Lin}\left[\ell_{2}\left(\mathbf{R}^{m}\right)\right]}^{2}$ by the square of the Frobenius norm $\sum_{i, k=1}^{m} \kappa_{i, k}^{2}$ and then apply part 1. Recall that the $L_{2}$-approximation is properly scaled for $Q$, i.e., that $\lambda_{\boldsymbol{\alpha}_{2, Q}[j]} \leq 1$ and $\gamma_{2 d, \mathfrak{u}(\boldsymbol{\alpha}), Q} \leq 1$ for all eigenvalues and weights. Thus, we have

$$
\begin{aligned}
\|\mathbf{K}\|_{\operatorname{Lin}\left[\ell_{2}\left(\mathbf{R}^{n(F)}\right)\right]}^{2} & \leq \sum_{i, k=1}^{m} \kappa_{i, k}^{2} \\
& =\sum_{(i, k) \in \mathscr{I}} \kappa_{i, k}^{2} \\
& \leq \sum_{j=1}^{n(Q)} \zeta_{j}^{2} \lambda_{\boldsymbol{\alpha}_{2, Q}[j]}^{2} \\
& =\sum_{j=1}^{n(Q)}\left\langle q, e_{j, 2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \boldsymbol{\gamma}_{Q}}}^{2} \gamma_{2 d, \mathfrak{u}\left(\boldsymbol{\alpha}_{Q}[j]\right), Q} \lambda_{\boldsymbol{\alpha}_{2, Q}[j]}^{2} \\
& \leq \sum_{j=1}^{n(Q)}\left\langle q, e_{j, 2 d, \boldsymbol{\gamma}_{Q}}\right\rangle_{H_{2 d, \boldsymbol{\gamma}_{Q}}}^{2} \\
& =\left\|P_{n(Q), 2 d, \boldsymbol{\gamma}_{Q}} q\right\|_{H_{2 d, \boldsymbol{\gamma}_{q}}}^{2} \\
& \leq\|q\|_{Q_{2 d}}^{2} \leq M_{1}^{2}<1,
\end{aligned}
$$

which proves part 2. Part 3 follows immediately from part 2.

We now discuss the implementation of the interpolatory algorithm $A_{n(F), n(Q)}^{\mathrm{INT}}$, which is equivalent to solving the linear equation $(\mathbf{I}-\mathbf{K}) \mathbf{u}=$ b. Note that the $m \times m$ matrix $\mathbf{K}$ is sparse, in the sense that it has at most $n(Q)$ nonzero elements; moreover, its norm is at most $M_{1}<1$, independent of the size of $m$. Therefore, it seems natural to approximate the solution $\mathbf{u}$ via the simple fixed-point iteration

$$
\begin{align*}
\mathbf{u}^{(\ell+1)} & =\mathbf{K} \mathbf{u}^{(\ell)}+\mathbf{b} \quad(0 \leq \ell<r), \\
\mathbf{u}^{(0)} & =\mathbf{0} \tag{32}
\end{align*}
$$

Letting

$$
\mathbf{u}^{(r)}=\left[v_{1}^{(r)}, v_{2}^{(r)}, \ldots, v_{m}^{(r)}\right]^{\top}
$$

we shall write

$$
u_{n(F), n(Q)}^{(r)}=\sum_{k=1}^{m} v_{k}^{(r)} z_{k}
$$

for our $r$-step fixed-point approximation to the exact solution

$$
\widetilde{u}=A_{n(F), n(Q)}^{\mathrm{INT}}(f, q)=\sum_{k=1}^{m} v_{k} z_{k}
$$

Let us write

$$
u_{n(F), n(Q)}^{(r)}=A_{n(F), n(Q), r}^{\mathrm{INT}}(f, q),
$$

calling $A_{n(F), n(Q), r}^{\mathrm{INT}}$ the modified interpolatory algorithm.
We now analyze the cost of computing $\widetilde{u}=A_{n(F), n(Q)}^{\mathrm{INT}}(f, q)$. How much do we lose when going from the interpolatory algorithm to the modified interpolatory algorithm? The answer is, "not much," if parameter $r$ is properly defined. Let $\operatorname{cost}(A)$ denote the overall cost of an algorithm $A$ for approximating the Fredholm problem, including the cost of both information and combinatory operations. We shall make the usual assumption, commonly made in information-based complexity theory, that arithmetic operations have unit cost and that one information operation of $f$ and $q$ have a fixed cost $\mathbf{c}_{d} \geq 1$. Now let

$$
\begin{aligned}
\operatorname{cost}(\varepsilon, & \left.A_{\varepsilon, d}^{\mathrm{INT}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right) \\
& =\inf \left\{\operatorname{cost}\left(A_{n(F), n(Q)}^{\mathrm{INT}}\right): e\left(A_{n(F), n(Q),}^{\mathrm{INT}}, S_{d}, \Lambda_{d, 2 d}^{\mathrm{all}}\right) \leq \varepsilon\right\}
\end{aligned}
$$

and

$$
\begin{aligned}
\operatorname{cost} & \left(\varepsilon, A_{\varepsilon, d}^{\mathrm{INT}-\mathrm{MOD}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right) \\
& =\inf \left\{\operatorname{cost}\left(A_{n(F), n(Q), r}^{\mathrm{INT}}\right): e\left(A_{n(F), n(Q), r}^{\mathrm{INT}}, S_{d}, \Lambda_{d, 2 d}^{\mathrm{all}}\right) \leq \varepsilon\right\}
\end{aligned}
$$

respectively, denote the minimal cost of using the interpolatory and modified interpolatory algorithms to find an $\varepsilon$-approximation of the Fredholm problem. That is, we minimize the cost by choosing proper parameters $n(F), n(Q)$ and $r$ of the modified interpolatory algorithm, and the parameters $n(F)$ and $n(Q)$ of the interpolatory algorithm.

## Proposition 6.1.

$$
\operatorname{cost}\left(\varepsilon, A_{\varepsilon, d}^{\mathrm{INT}-\mathrm{MOD}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right)=\mathbf{c}_{d} \cdot \Theta\left(n\left(\frac{1}{2} \varepsilon, A_{\varepsilon, d}^{\mathrm{INT}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right) \ln \left(\frac{1}{\varepsilon}\right)\right)
$$

where the $\Theta$-factor is independent of $d$ and $\varepsilon$. Hence, if

$$
\begin{equation*}
n\left(\frac{1}{2} \varepsilon, A_{\varepsilon, d}^{\mathrm{INT}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right)=\mathscr{O}\left(n\left(\varepsilon, A_{\varepsilon, d}^{\mathrm{INT}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right)\right) \tag{33}
\end{equation*}
$$

with $\mathscr{O}$-factor independent of $d$ and $\varepsilon$, then

$$
\operatorname{cost}\left(\varepsilon, A_{\varepsilon, d}^{\mathrm{INT}-\mathrm{MOD}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right)=\mathbf{c}_{d} \cdot \Theta\left(n\left(\varepsilon, A_{\varepsilon, d}^{\mathrm{INT}}, \Lambda_{d, 2 d}^{\mathrm{all}}\right) \ln \left(\frac{1}{\varepsilon}\right)\right)
$$

Proof. Recall that $\mathbf{K}$ has $n(Q)$ non-zero elements, see Lemma 6.1. Hence, each iteration of (32) can be done in $\Theta(n(F)+n(Q))$ arithmetic additions and multiplications. Thus, the total number of arithmetic operations needed to compute $u_{n(F), n(Q)}^{(r)}$ will be $\Theta((n(F)+n(Q)) r)$.

For a given value of $\varepsilon \in(0,1)$, let us choose $n(F)$ and $n(Q)$ so that the solution $\widetilde{u}$ of the interpolatory algorithm satisfies

$$
\|u-\widetilde{u}\|_{L_{2}\left(I^{d}\right)} \leq \frac{1}{2} \varepsilon .
$$

Obviously, it is enough to choose $r$ such that

$$
\begin{equation*}
\left\|\widetilde{u}-u_{n(F), n(Q)}^{(r)}\right\|_{L_{2}\left(I^{d}\right)} \leq \frac{1}{2} \varepsilon \tag{34}
\end{equation*}
$$

and then our approximation $u_{n(F), n(Q)}^{(r)} \in L_{2}\left(I^{d}\right)$ will satisfy

$$
\begin{equation*}
\left\|u-u_{n(F), n(Q)}^{(r)}\right\|_{L_{2}\left(I^{d}\right)} \leq \varepsilon \tag{35}
\end{equation*}
$$

as required.
So let's analyze the convergence of the fixed-point iteration (32). From Lemma 6.1, we know that
$\|\mathbf{K}\|_{\operatorname{Lin}\left[\ell_{2}\left(\mathbf{R}^{m}\right)\right]} \leq M_{1}<1 \quad$ so that $\quad\left\|(\mathbf{I}-\mathbf{K})^{-1}\right\|_{\operatorname{Lin}\left[\ell_{2}\left(\mathbf{R}^{m}\right)\right]} \leq \frac{1}{1-M_{1}}$.
Each iteration of (32) reduces the error by a factor of $M_{1}$, i.e.,

$$
\left\|\mathbf{u}-\mathbf{u}^{(\ell+1)}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} \leq M_{1}\left\|\mathbf{u}-\mathbf{u}^{(\ell)}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} \quad(0 \leq \ell<r)
$$

and so

$$
\begin{aligned}
\left\|\mathbf{u}-\mathbf{u}^{(r)}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} & \leq M_{1}^{r}\|\mathbf{u}\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} \\
& =M_{1}^{r}\left\|(\mathbf{I}-\mathbf{K})^{-1} \mathbf{b}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} \\
& \leq \frac{M_{1}^{r}}{1-M_{1}}\|\mathbf{b}\|_{\ell_{2}\left(\mathbf{R}^{m}\right)}
\end{aligned}
$$

Finally, since $f \in B F_{d}$, we have

$$
\begin{aligned}
\|\mathbf{b}\|_{\ell_{2}\left(\mathbf{R}^{m}\right)}^{2} & =\sum_{j=1}^{n(F)}\left\langle f, e_{j, d, \gamma_{F}}\right\rangle_{F_{d}}^{2} \gamma_{d, \mathfrak{u}\left(\boldsymbol{\alpha}_{F}[j]\right), F} \\
& \leq \sum_{j=1}^{n(F)}\left\langle f, e_{j, d, \gamma_{F}}\right\rangle_{F_{d}}^{2}=\left\|P_{n(F), d, \boldsymbol{\gamma}_{F}} q\right\|_{F_{d}} \\
& \leq\|f\|_{F_{d}}^{2} \leq 1
\end{aligned}
$$

and thus the previous inequality becomes

$$
\left\|\mathbf{u}-\mathbf{u}^{(r)}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} \leq \frac{M_{1}^{r}}{1-M_{1}}
$$

Taking

$$
\begin{equation*}
r=\left\lceil\frac{\ln \left(2 /\left(1-M_{1}\right)\right)+\ln 1 / \varepsilon}{\ln 1 / M_{1}}\right\rceil=\Theta\left(\ln \frac{1}{\varepsilon}\right) \tag{36}
\end{equation*}
$$

we thus have

$$
\begin{equation*}
\left\|\mathbf{u}-\mathbf{u}^{(r)}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} \leq \frac{1}{2} \varepsilon \tag{37}
\end{equation*}
$$

We now claim that, with $r$ given by (36), we have (34). Indeed, note that, since the $L_{2}\left(I^{d}\right)$ approximation problem is properly scaled over $F_{d}$ and over $Q_{d}$, we have $\lambda_{\boldsymbol{\alpha}_{F}[j], d, \gamma_{F}}, \lambda_{\boldsymbol{\alpha}_{1, Q}\left[l_{j}-n(F)\right], d, \boldsymbol{\gamma}_{Q}} \leq 1$ for all $j \in \mathbf{N}$. Then

$$
\begin{aligned}
\left\|\widetilde{u}-u_{n(F), n(Q)}^{(r)}\right\|_{L_{2}\left(I^{d}\right)}^{2}= & \sum_{j=1}^{m}\left(v_{j}-v_{j}^{(r)}\right)^{2}\left\|z_{j}\right\|_{L_{2}\left(I^{d}\right)}^{2} \\
= & \sum_{j=1}^{n(F)}\left(v_{j}-v_{j}^{(r)}\right)^{2} \lambda_{\boldsymbol{\alpha}_{F}[j], d, \gamma_{F}} \\
& +\sum_{j=n(F)+1}^{m}\left(v_{j}-v_{j}^{(r)}\right)^{2} \lambda_{\boldsymbol{\alpha}_{1, Q}\left[l_{j}-n(F)\right], d, \gamma_{Q}} \\
\leq & \sum_{j=1}^{m}\left(v_{j}-v_{j}^{(r)}\right)^{2} \\
= & \left\|\mathbf{u}-\mathbf{u}^{(r)}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)}
\end{aligned}
$$

and so

$$
\left\|\widetilde{u}-u_{n(F), n(Q)}^{(r)}\right\|_{L_{2}\left(I^{d}\right)} \leq\left\|\mathbf{u}-\mathbf{u}^{(r)}\right\|_{\ell_{2}\left(\mathbf{R}^{m}\right)} \leq \frac{1}{2} \varepsilon
$$

establishing (34), as claimed.
Since (34) holds, we have our desired result (35). Hence, we have computed an $\varepsilon$-approximation with information cost $\Theta\left(\mathbf{c}_{d}(n(F)+n(Q))\right)$ and combinatory cost $\Theta([n(F)+n(Q)] \ln (1 / \varepsilon))$, and so the result follows.

Using Proposition 6.1, along with the results in Section 3, we see that when (33) holds, the modified interpolatory algorithm is within a logarithmic factor of being optimal. Such is the case when the Fredholm problem (or, alternatively, the $L_{2}$-approximation problems $\mathrm{APP}_{F}$ and $\mathrm{APP}_{Q}$ ) is strongly polynomially tractable or polynomially tractable. Obviously, the extra factor $\ln (1 / \varepsilon)$ does not change the exponents of strong polynomial or polynomial tractability.

Acknowledgments. We are pleased to thank Erich Novak for his comments; we also thank the referees for their careful reading of the original version of this paper.

## ENDNOTES

1. But not always, see [14].
2. In fact, one can take $I$ as a measurable subset of $\mathbf{R}$ with a positive Lebesgue measure and define $L_{2}(I)$ with a weight $\rho$ such that $\int_{I} \rho(t) d t=1$. We take $I=[0,1]$ for simplicity.
