# Correction of the Semantics for S4.03 and a Note on Literal Disjunctive Symmetry 

RALPH H. MOON

The term disjunctive symmetry, designating that property possessed by a Kripke-model $\langle W, R, v\rangle$ just in case for each $x \in W$
(i) $\quad(\exists y)\left[x R y \&\left(x^{\prime}\right)\left(y^{\prime}\right)\left[\left(x R x^{\prime} \& y R y^{\prime}\right) \supset\left(x^{\prime} R x \vee y^{\prime} R x^{\prime}\right)\right]\right]$,
was defined in Georgacarakos's [2] where it was argued that $S 4.03$-that is, $S 4($ I1 ), the system obtained by adding each substitution instance of
I1 $L(L p \rightarrow q) \vee(L M L q \rightarrow p)$
to $S 4$-is characterized by the class of disjunctively symmetrical $S 4$-models.
At first sight, this characterization seems altogether fitting: I1 is a weakened version of

## F $\quad L(L p \rightarrow q) \vee(M L q \rightarrow p)$,

the proper axiom for $S 4.3 .2$; and the condition used to define disjunctive symmetry is, similarly, a weakening of
(ii) $\quad(x)(y)[(x R y \& x R z) \supset(z R y \vee y R x)]$,
which specifies a class of $S 4$-models known to characterize $S 4.3 .2$ (see, e.g., [4], Lemma 7.10). It turns out, however, that the appearance of having simultaneously relaxed semantic and syntactic constraints is deceptive. For, although $S 4.03$ is a proper subsystem of $S 4.3 .2$ (see [1]), the system characterized by the class of disjunctively symmetrical $S 4$-models is not; rather, it is identical with S4.3.2, a fact that will be proved shortly (Theorem 1).

From all this we must conclude that there is an error in the proof of the main result of [2] and that a new semantics for $S 4.03$ is needed. ${ }^{1}$ Theorem 2, below, accomplishes this latter task. The paper ends with a brief look at a family of (mostly) new extensions of $S 4$, each of which is characterized by a class of $S 4$-models whose members are disjunctively symmetrical in a somewhat more literal sense of the term than that mentioned above.

Considerable use will be made of post-Henkin style completeness proofs and of filtration theory as developed by Segerberg in [4]. The reader is presumed to be familiar with the terminology, methods, and results of this reference.

Theorem $1 \quad$ S4.3.2 is characterized by the class of disjunctively symmetrical S4-models.

Proof:
Soundness. Suppose that some instance

$$
L(L \alpha \rightarrow \beta) \vee(M L \beta \rightarrow \alpha)
$$

of $\mathbf{F}$ is false at a point $x$ in an $S 4$-model $\langle W, R, v\rangle$ satisfying (i). Then
(a) $\quad L(L \alpha \rightarrow \beta)$ is false at $x$
and
(b) $\quad M L \beta$ is true at $x$
while
(c) $\quad \alpha$ is false at $x$.

By (a), there is a point $x_{1}^{\prime}$ such that $x R x_{1}^{\prime}$ and
(d) $\quad L \alpha$ is true at $x_{1}^{\prime}$
and
(e) $\quad \beta$ is false at $x_{1}^{\prime}$.

Moreover, by (b), there is a point $x_{2}^{\prime}$ such that $x R x_{2}^{\prime}$ and
(f) $\quad L \beta$ is true at $x_{2}^{\prime}$.

Since $\langle W, R, v\rangle$ satisfies (i), there is a point $y$ such that $x R y$ and
(g) $\quad\left(x^{\prime}\right)\left(y^{\prime}\right)\left[\left(x R x^{\prime} \& y R y^{\prime}\right) \supset\left(x^{\prime} R x \vee y^{\prime} R x^{\prime}\right)\right]$.

Now, given (c) and (d), $x_{1}^{\prime} \mathbb{R} x$; so, by (g),
(h) $\quad\left(y^{\prime}\right)\left(y R y^{\prime} \supset y^{\prime} R x_{1}^{\prime}\right)$.

Similarly, (e) and (f) require that $x_{2}^{\prime} \mathbb{R} x$; so, by (g) again,
(j) $\quad\left(y^{\prime}\right)\left(y R y^{\prime} \supset y^{\prime} R x_{2}^{\prime}\right)$.

Taken together, (h) and (e) imply that
(k) $\quad M L \beta$ is false at $y$.

On the other hand, (j) and (f) imply that
(1) $\quad L M L \beta$ is true at $y$.

This, however, contradicts (k).
Completeness. The canonical model for $S 4.3 .2, K_{S 4.3 .2}$, is known to satisfy (ii) (see, e.g., [4], Lemma 7.10), and (i) is readily deducible from (ii) in the presence of reflexivity. $K_{S 4.3 .2}$ is therefore disjunctively symmetrical.
Theorem $2 \quad S 4.03$ is characterized by the class of S4-models satisfying
(iii) $\quad(x)(y)\left[(x R y \supset y R x) \vee(\exists z)\left[x R z \&\left(z^{\prime}\right)\left(z R z^{\prime} \supset z^{\prime} R y\right)\right]\right]$.

Proof:
Soundness. Suppose that some instance

$$
L(L \alpha \rightarrow \beta) \vee(L M L \beta \rightarrow \alpha)
$$

of I1 fails at a point $x$ in an $S 4$-model $\langle W, R, v\rangle$ satisfying (iii). Then
(m) $\quad L(L \alpha \rightarrow \beta)$ is false at $x$
and
(n) $\quad L M L \beta$ is true at $x$
but
(o) $\quad \alpha$ is false at $x$.

By (m), there is a point $y$ such that $x R y$ and
(p) $\quad L \alpha$ is true at $y$
while
(q) $\quad \beta$ is false at $y$.

Given that $x R y$ and $y \mathbb{R} x$ (by (o) and (p)), (iii) requires that there be a point $z$ such that $x R z$ and
(r) $\quad\left(z^{\prime}\right)\left(z R z^{\prime} \supset z^{\prime} R y\right)$.

By (n), $M L \beta$ is true at $z$; so there is a point $z^{\prime}$ such that $z R z^{\prime}$ and
(s) $\quad L \beta$ is true at $z^{\prime}$.

Together, (r) and (s) imply that $\beta$ is true at $y$; but this contradicts (q).
Completeness. Suppose that $\gamma$ is a nontheorem of S4.03. Then there is a point $t$ in the canonical model for $S 4.03, K_{S 4.03}$, at which $\gamma$ is false. Let $\Psi$ be the smallest set containing $\gamma$ that is closed under the formation of subformulas and modalities ( $\Psi$ will be finite, since $S 4.03$ is a normal extension of $S 4$ ), and let $K^{\prime}=\left\langle W^{\prime}, R^{\prime}, v^{\prime}\right\rangle$ be a Lemmon-filtration of $K_{S 4.03}$ through $\Psi . K^{\prime}$ will be finite, reflexive, and transitive; and $\gamma$ will fail at $[t]$ in $K^{\prime}$.

All that remains to be shown is that $K^{\prime}$ satisfies (iii). So suppose, for a reductio, that it does not. Then there are points $[x]$ and $[y]$ in $W^{\prime}$ such that $[x] R^{\prime}[y]$ but
(t) $\quad[y] \mathbb{R}^{\prime}[x]$.

Moreover,
(u) $([z])\left\{[x] R^{\prime}[z] \supset\left(\exists\left[z^{\prime}\right]\right)\left([z] R^{\prime}\left[z^{\prime}\right] \&\left[z^{\prime}\right] \not R^{\prime}[y]\right)\right\}$.

Given that $K^{\prime}$ is a Lemmon-filtration, (t) and the Filtration Theorem ([4], p. 66) imply that there is a formula $L \alpha \in \Psi$ such that
(v) $L \alpha$ is true at $[y]$
but
(w) $\quad L \alpha$ is false at $[x]$.

Since $K^{\prime}$ is finite, $[x]$ bears $R^{\prime}$ to at most finitely many points in $W^{\prime}$-say $\left[z_{1}\right], \ldots,\left[z_{n}\right]$; and by (u), for each $1 \leqslant i \leqslant n$, there is a point $\left[z_{i}^{\prime}\right]$ such that $\left[z_{i}\right] R^{\prime}\left[z_{i}^{\prime}\right]$ and
(x) $\left[z_{i}^{\prime}\right] \mathbb{R}^{\prime}[y]$.

Consequently, there are formulas $L \beta_{1}, \ldots, L \beta_{n} \in \Psi$ such that for each $1 \leqslant i \leqslant n$
(y) $\quad L \beta_{i}$ is true at $\left[z_{i}^{\prime}\right]$
while
(z) $\quad L \beta_{i}$ is false at $[y]$.

By Theorem 7.5 of [4], $K^{\prime}$ is a finest filtration, which implies that there is a point $u \in[x]$ and a point $w \in[y]$ such that $u R_{S 4.03} w$. With $L \alpha \in \Psi$ and $u \in[x]$, (w) and the Filtration Theorem guarantee that
( $\left.a^{\prime}\right) \quad L \alpha$ is false at $u$.
Similarly, since $L \alpha, L \beta_{1}, \ldots, L \beta_{n} \in \Psi$ and $w \in[y]$, (v), and (z) imply that
(b') $\quad L \alpha$ is true at $w$
and, for $1 \leqslant i \leqslant n$,
(c') $L \beta_{i}$ is false at $w$.
From ( $\mathrm{b}^{\prime}$ ) and ( $\mathrm{c}^{\prime}$ ) we may conclude that $L\left(L \alpha \rightarrow \sum_{i} L \beta_{i}\right)$ is false at $u$ and,
therefore, that
(d') $\quad L\left(L L \alpha \rightarrow \sum_{i} \beta_{i}\right)$ is false at $u$.
Pick any point $u^{\prime}$ such that $u R_{S 4.03} u^{\prime}$. Then $[u] R^{\prime}\left[u^{\prime}\right]-$ that is, $[x] R^{\prime}\left[u^{\prime}\right]-$ which means $\left[u^{\prime}\right]=\left[z_{i}\right]$, for some $1 \leqslant i \leqslant n$. Say $\left[u^{\prime}\right]=\left[z_{j}\right]$. By (y), this implies that $M L \beta_{j}$ is true at $\left[u^{\prime}\right]$; and since $M L \beta_{j} \in \Psi, M L \beta_{j}$ is true at $u^{\prime}$, from which it follows that $M L\left(\sum_{i} L \beta_{i}\right)$ is true at $u^{\prime}$. As $u^{\prime}$ was selected arbitrarily,
(e') $\quad L M L\left(\sum_{i} L \beta_{i}\right)$ is true at $u$.
Finally, letting $\sigma=L \alpha$ and $\tau=\sum_{i} L \beta_{i}$, we have, by ( $\mathrm{a}^{\prime}$ ), ( $\mathrm{d}^{\prime}$ ), and ( $\mathrm{e}^{\prime}$ ), that

$$
L(L \sigma \rightarrow \tau) \vee(L M L \tau \rightarrow \sigma) \text { is false at } u
$$

in $K_{S 4.03}$, which is impossible.
Corollary $3 \quad S 4.03$ is decidable.
Proof: The completeness portion of the proof of Theorem 2 shows that $S 4.03$ has the finite model property; and this, together with the finite axiomatizability of $S 4.03$, guarantees decidability.

When taken together with the semantic characterizations of S4.01, Z1, and $K 1$ known in the literature, Theorem 2 also yields semantics for $S 4.01$ (I1), Z1(I1), and $K 1(\mathbf{I} 1)$-systems introduced by Georgacarakos in [1], where they are called $S 4.05, Z 1.5$, and $K 1.1 .5$, respectively. In particular, defining an $S 4.03$-model to be an $S 4$-model satisfying (iii), we have

Corollary $4 \quad$ (a) $S 4.05$ is characterized by the class of finite S4.03-models in which every proper final cluster is last; (b) K1.1.5 is characterized by the class of S4.03-models in which each point is contained in or precedes a simple final cluster; and (c) Z1.5 is characterized by the class of S4.03-models that satisfy
(iv) $\quad(x)(y)\left[(x R y \supset y R x) \vee(\exists z)\left[y R z \&\left(z^{\prime}\right)\left(z R z^{\prime} \supset z^{\prime}=z\right)\right]\right]$.

After working with disjunctive symmetry as it is defined at the start of this paper, it is natural to wonder which extensions of $S 4$ are characterized by those classes of Kripke-models that are disjunctively symmetrical in the more literal sense of the phrase. Put more precisely, we want to know, for each $n \geqslant 1$, what system is characterized by the class of $S 4$-models that satisfy
$\operatorname{LDS}_{\boldsymbol{n}} \quad(x)\left(y_{1}\right) \ldots\left(y_{n}\right)\left[\left(\prod_{i} x R y_{i} \& \prod_{i<j} y_{i} \neq y_{j}\right) \supset \sum_{i} y_{i} R x\right]$.
An answer is easily obtained, and we shall state it without proof as
Theorem 5 Let $\operatorname{LDS}_{n}$ be the formula

$$
p \vee L\left(L p \rightarrow q_{1}\right) \vee \ldots \vee L\left[\left(L p \& \prod_{1 \leqslant i<n} q_{i}\right) \rightarrow q_{n}\right] .
$$

Then, for each $n \geqslant 1, S 4\left(\mathbf{L D S}_{n}\right)$ is characterized by the class of $S 4$-models satisfying LDS $_{n}$.
$S 4\left(\right.$ LDS $\left._{1}\right)$ is obviously just $S 5$. Not so obvious, perhaps, is the fact that $S 4\left(\mathbf{L D S}_{2}\right)$ is also a system known in the literature, namely, $Z 8$. This will be proved in several stages, beginning with

Lemma 6 Each substitution instance of LDS $_{2}$ is a theorem of $Z 8$.
Proof: $Z 8$ is characterized by the class of $S 4$-models that satisfy (ii) and (iv); so if some instance

$$
\alpha \vee L(L \alpha \rightarrow \beta) \vee L[(L \alpha \& \beta) \rightarrow \gamma]
$$

of $\mathrm{LDS}_{2}$ were a nontheorem of $Z 8$, it would have to fail in an $S 4$-model $\langle W, R, v\rangle$ satisfying both of those conditions. We assume, for a reductio, that it does. Then there is a point $x \in W$ such that
(f') $\quad \alpha$ is false at $x$
and
( $\left.\mathrm{g}^{\prime}\right) \quad L(L \alpha \rightarrow \beta)$ is false at $x$
and
(h') $\quad L[(L \alpha \& \beta) \rightarrow \gamma]$ is false at $x$.
By $\left(\mathrm{g}^{\prime}\right)$, there is a point $y$ such that $x R y$ and
$\left(\mathrm{j}^{\prime}\right) \quad L \alpha$ is true at $y$
while
( $\mathrm{k}^{\prime}$ ) $\quad \beta$ is false at $y$.
Similarly, by ( $\mathrm{h}^{\prime}$ ), there is a point $z$ such that $x R z$ and
( $1^{\prime}$ ) $\quad L \alpha \& \beta$ is true at $z$
while
( $\mathrm{m}^{\prime}$ ) $\quad \gamma$ is false at $z$.
Now ( $\mathrm{f}^{\prime}$ ) and ( $\mathrm{j}^{\prime}$ ) imply that
$\left(\mathrm{n}^{\prime}\right) \quad y \mathbb{R} x$
and ( $\mathrm{f}^{\prime}$ ) and ( $\mathrm{l}^{\prime}$ ) imply that
( $\mathrm{o}^{\prime}$ ) $\quad z \not R x$.
Further, ( $\mathrm{o}^{\prime}$ ) and condition (ii) yield
( $\mathrm{p}^{\prime}$ ) $\quad y R z$.
By ( n ') and condition (iv), $y$ bears $R$ to a 'terminal' point $z$ '; and since $y R z$ but $z \neq y$ (by ( $\mathrm{k}^{\prime}$ ) and ( $\mathrm{l}^{\prime}$ )), $z^{\prime}$ must be distinct from $y$. This, in light of the fact that $z^{\prime}$ is terminal, means that
( $\mathrm{q}^{\prime}$ ) $\quad z^{\prime} R \mathbb{R} y$.
But $x R y$ and $x R z^{\prime}$; thus ( $\mathrm{q}^{\prime}$ ) and (ii) give

$$
y R x
$$

contradicting ( $\mathrm{n}^{\prime}$ ).
The straightforward semantic proof of the following lemma is left to the reader.

Lemma 7 Each substitution instance of $\mathbf{F}$ is a theorem of $S 4\left(\mathbf{L D S}_{2}\right)$.
Lemma 8 Each substitution instance of
Z2

$$
L(L M p \rightarrow M L p) \vee L(M q \rightarrow L M q)
$$

is a theorem of $S 4\left(\mathbf{L D S}_{2}\right)$.
Proof: Suppose an instance

$$
L(L M \alpha \rightarrow M L \alpha) \vee L(M \beta \rightarrow L M \beta)
$$

of $\mathbf{Z 2}$ were to fail in an $S 4$-model $\langle W, R, v\rangle$ satisfying $L D S_{2}$. Then there would be a point $x \in W$ such that
(r) $\quad L(L M \alpha \rightarrow M L \alpha)$ is false at $x$
and
$\left(\mathrm{s}^{\prime}\right) \quad L(M \beta \rightarrow L M \beta)$ is false at $x$.
$\mathrm{By}\left(\mathrm{r}^{\prime}\right)$, there is a point $y$ such that $x R y$ and
( $\mathrm{t}^{\prime}$ ) $\quad L M \alpha$ is true at $y$
while
( $u^{\prime}$ ) $\quad M L \alpha$ is false at $y$.
Now ( $\mathrm{t}^{\prime}$ ), in the presence of reflexivity, guarantees that $y$ bears $R$ to a point at which $\alpha$ is true; and if $\alpha$ is false at $y$, then that point must be distinct from $y$. Similarly, ( $u^{\prime}$ ) guarantees that $y$ bears $R$ to a point at which $\alpha$ is false; and if $\alpha$ is true at $y$, then that point is distinct from $y$. So we may conclude that there is a point $z$ such that $y R z$ and $y \neq z$. But this, together with $L D S_{2}$ and the fact that $x R y$, requires that $y R x$. Consequently,
( $\mathrm{v}^{\prime}$ ) $\quad L M \alpha$ is true at $x$
and
( $\mathrm{w}^{\prime}$ ) $\quad M L \alpha$ is false at $x$.
By ( $\mathrm{s}^{\prime}$ ), there is a point $u$ such that $x R u$ and
( $\mathrm{x}^{\prime}$ ) $\quad M \beta$ is true at $u$
but
( $\mathrm{y}^{\prime}$ ) $\quad L M \beta$ is false at $u$.
And, by ( $\mathrm{y}^{\prime}$ ), there is a point $v$ such that $u R v$ and
( $\left.\mathrm{z}^{\prime}\right) \quad M \beta$ is false at $v$.
Since $x R v,\left(v^{\prime}\right)$ and ( $\mathrm{w}^{\prime}$ ) imply that
( $\mathrm{a}^{\prime \prime}$ ) $\quad M \alpha$ is true at $v$
and
( $\mathrm{b}^{\prime \prime}$ ) $\quad L \alpha$ is false at $v$.
Employing an argument similar to the one used in establishing ( $\mathrm{v}^{\prime}$ ) and ( $\mathrm{w}^{\prime}$ ), we may infer from ( $\mathrm{a}^{\prime \prime}$ ) and ( $\mathrm{b}^{\prime \prime}$ ) that there is a point $w$ such that $v R w$ and $v \neq w$. Given $L D S_{2}$ and the fact that $u R v$, it follows that $v R u$ and so, by ( $z^{\prime}$ ), that
( $\mathrm{c}^{\prime \prime}$ ) $\quad M \beta$ is false at $u$.
This, however, contradicts ( $\mathrm{x}^{\prime}$ ).

Since $Z 8$ is $S 4(\mathbf{F}, \mathbf{Z 2})$, Lemmas 6, 7, and 8 suffice for
Theorem $9 \quad S 4\left(\mathrm{LDS}_{2}\right)=Z 8$.
Theorems 5 and 9, taken together, provide a new semantic characterization of $Z 8$. At least one other result of this sort can also be obtained using Theorem 9. Defining an $S 4.3 .2$-model to be an $S 4$-model satisfying (ii), we have

Corollary $10 \quad Z 8$ is characterized by the class of S4.3.2-models in which every proper cluster is first.

Proof: The proof of soundness-that each instance of LDS $_{2}$ is valid in each $S 4.3 .2$-model satisfying the stated condition-is left to the reader.

Completeness. Assume that $\gamma$ is a nontheorem of $Z 8$. Then $\gamma$ fails at a point $t$ in the canonical model $K_{Z 8}$ for $Z 8$. Moreover, $K_{Z 8}$ satisfies (ii), since $Z 8$ is an extension of S4.3.2.

Let $K^{\prime}=\left\langle W^{\prime}, R^{\prime}, v^{\prime}\right\rangle$ be the model generated from $K_{Z 8}$ by $t$. Then $K^{\prime}$, too, satisfies (ii) and rejects $\gamma$ at $t$ (see [4], Theorem 3.10). Now suppose that $K^{\prime}$ fails to satisfy the stated condition. This can only mean that there is a proper cluster $C$ in $K^{\prime}$ which is not first. Thus there is a point $z \in W^{\prime}$ to which none of the points in $C$ bears $R^{\prime}$.

Let $x$ and $y$ be distinct points in $C$. Then
( $\mathrm{d}^{\prime \prime}$ ) $\quad x \mathbb{R}^{\prime} z$.
Since $t$ generates $K^{\prime}$,
( $\mathrm{e}^{\prime \prime}$ ) $t R^{\prime} x$
(f $\left.\mathrm{f}^{\prime \prime}\right) \quad t R^{\prime} y$
and
( $\left.\mathrm{g}^{\prime \prime}\right) \quad t R^{\prime} z$.
By ( $\mathrm{d}^{\prime \prime}$ ), ( $\mathrm{g}^{\prime \prime}$ ), and transitivity,
( $\mathrm{h}^{\prime \prime}$ ) $x \mathbb{R}^{\prime} t$.
Therefore, there is a formula $\alpha$ such that
( $\mathrm{j}^{\prime \prime}$ ) $\quad L \alpha$ is true at $x$
while
( $\mathrm{k}^{\prime \prime}$ ) $\quad \alpha$ is false at $t$.
But $x$ and $y$ are in the same cluster; so
( $1^{\prime \prime}$ ) $L \alpha$ is true at $y$
as well; and, moreover, since $x \neq y$, there is a formula $\beta_{1}$ such that
( $\mathrm{m}^{\prime \prime}$ ) $\beta_{1}$ is true at $y$
but
$\left(\mathrm{n}^{\prime \prime}\right) \quad \beta_{1}$ is false at $x$.

By ( $\mathrm{l}^{\prime \prime}$ ) and ( $\mathrm{m}^{\prime \prime}$ ),
( $\mathrm{o}^{\prime \prime}$ ) $\quad\left(L \alpha \& \beta_{1}\right) \rightarrow \sim \beta_{1}$ is false at $y$
and, by ( $\mathrm{j}^{\prime \prime}$ ) and ( $\mathrm{n}^{\prime \prime}$ )
( $\mathrm{p}^{\prime \prime}$ ) $\quad L \alpha \rightarrow \beta_{1}$ is false at $x$.
Putting ( $\mathrm{k}^{\prime \prime}$ ), ( $\mathrm{o}^{\prime \prime}$ ), and ( $\mathrm{p}^{\prime \prime}$ ) together with ( $\mathrm{e}^{\prime \prime}$ ) and ( $\left.\mathrm{f}^{\prime \prime}\right)$, we may infer that an instance of $\mathrm{LDS}_{2}$, namely,

$$
\left.\alpha \vee L\left(L \alpha \rightarrow \beta_{1}\right) \vee L\left[L \alpha \& \beta_{1}\right) \rightarrow \sim \beta_{1}\right]
$$

is false at $t$; but, given Theorem 9 , this is impossible.
As for the remaining members of the $S 4\left(\mathrm{LDS}_{n}\right)$ family, semantic considerations readily show that each, save $S 4\left(\mathrm{LDS}_{3}\right)$, is a proper subsystem of $Z 8$ and its extensions, independent of the other well-known extensions of $S 4$ (for which, see the diagram on p. 574 of [3]) and of $S 4.03, Z 1.5$, and K1.1.5. The account of $S 4\left(\mathrm{LDS}_{3}\right)$ differs only in that it is a proper extension of $S 4.01$.

## NOTE

1. The error occurs on p. 506 of [2]: $L M L \gamma \in \Gamma_{i}$ is inferred from $M L \gamma \in \Gamma_{j}$, when the latter only warrants the conclusion that $M L \gamma \in \Gamma_{i}$.
