# AN ELLIPTIC SURFACE COVERED BY MUMFORD'S FAKE PROJECTIVE PLANE 

Dedicated to Professor Masayoshi Nagata on his sixtieth birthday<br>Masa-Nori Ishida

(Received January 28, 1987)

Introduction. In [Mum], Mumford constructed an algebraic surface $M$ of general type with $K_{M}{ }^{2}=9$ and $p_{g}=q=0$. This surface is called Mumford's fake projective plane because it has the same Betti numbers as the complex projective plane (see [BPV, Historical Note]). No other example of fake projective planes in this sense seems to be known up to now.

Since $c_{1}{ }^{2}(M)=3 c_{2}(M)=9$, the universal covering space of the complex surface $M$ is isomorphic to the unit ball in $C^{2}$ by Yau's result. However, Mumford's surface is constructed by means of the theory of the $p$-adic unit ball by Kurihara [Ku] and Mustafin [Mus]. By the construction of $M$, there exists an unramified Galois covering $V \rightarrow M$ of order eight. More precisely, a simple group $G$ of order 168 acts on $V$, and $M$ is the quotient of $V$ by a 2 -Sylow subgroup of $G$.

In this paper, we study the quotient surface $Y=V / G$. Since the action has fixed points, $Y$ has some singular points. We prove that the minimal desingularization $\tilde{Y}$ of $Y$ is an elliptic surface. We also determine the types of the singular fibers of the elliptic fibration.

Mumford's surface $M$ is given as a $\boldsymbol{Z}_{2}$-scheme. Hence it has a modulo 2 reduction $M_{0}$. The normalization $\widetilde{M}_{0}$ of $M_{0}$ is the blowing-up of $P_{P_{2}}^{2}$ at the seven $\boldsymbol{F}_{2}$-rational points. In Section 1, we describe explicitly how to recover $M_{0}$ from $\widetilde{M}_{0}$.

The author expresses his thanks to Professors F. Hirzebruch and I. Nakumura for their interest and suggestion on this work. Some results and techniques in Sections 3 and 4 are due to Nakamura in unpublished notes.

Notation. Let $X$ be a scheme over an affine scheme Spec A. When a ring homomorphism $A \rightarrow B$ is given, we denote by $X_{B}$ the fiber product $X \times_{\mathrm{sppec} A} \operatorname{Spec} B$ and by $X(B)$ the set of $B$-valued points of $X$. If $X$ is of finite type and $B$ is an algebraically closed field, then we sometimes treat $X(B)$ as a variety.

1. The closed fiber of Mumford's surface. We will recall some notation in Mumford's paper [Mum].

We always restrict ourselves to the case of the base ring $\boldsymbol{Z}_{2}$. Hence the maximal ideal is generated by 2 , and the quotient field is the 2 -adic number field $\boldsymbol{Q}_{2}$. We denote by $\eta$ and 0 the generic point and the closed point of $\operatorname{Spec} \boldsymbol{Z}_{2}$, respectively.

A matrix $\alpha=\left(a_{i, j}\right)_{i, j=0,1,2} \in G L\left(3, \boldsymbol{Q}_{2}\right)$ defines a linear automorphism of the vector space $\boldsymbol{Q}_{2} X_{0}+\boldsymbol{Q}_{2} X_{1}+\boldsymbol{Q}_{2} X_{2}$ with indeterminates $X_{0}, X_{1}, X_{2}$ by

$$
\alpha\left(c_{0} X_{0}+c_{1} X_{1}+c_{2} X_{2}\right)=\left(X_{0}, X_{1}, X_{2}\right) \alpha^{t}\left(c_{0}, c_{1}, c_{2}\right)=\sum_{i}\left(\sum_{j} a_{i, j} c_{j}\right) X_{i}
$$

Hence the induced automorphism $\alpha^{\wedge}$ of $\boldsymbol{P}_{\boldsymbol{Q}_{2}}^{2}=\operatorname{Proj} \boldsymbol{Q}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ is given in terms of the homogeneous coordinates ( $X_{0}: X_{1}: X_{2}$ ) by

$$
\alpha^{\wedge}\left(X_{0}: X_{1}: X_{2}\right)=\left(X_{0}: X_{1}: X_{2}\right) \alpha
$$

Thus the composite $\beta^{\wedge} \circ \alpha^{\wedge}$ is equal to $(\alpha \beta)^{\wedge}$.
The $Z_{2}$-scheme $\mathscr{X}$ of Kurihara and Mustafin is defined as follows:
Let $P_{Z_{2}}^{2}$ be the projective plane with the homogeneous coordinates $\left(X_{0}: X_{1}: X_{2}\right)$. The closed fiber $\boldsymbol{P}_{F_{2}}^{2}$ has seven $\boldsymbol{F}_{2}$-rational points and seven $\boldsymbol{F}_{2}$-rational lines. We first blow up $\boldsymbol{P}_{\boldsymbol{Z}_{2}}^{2}$ at these seven $\boldsymbol{F}_{2}$-rational points, and then blow up the resulting surface further along the proper transform of the union of the seven $\boldsymbol{F}_{2}$-rational lines. Let $U$ be the union of the generic fiber $\boldsymbol{P}_{\mathbf{Q}_{2}}^{2}$ and a sufficiently small open neighborhood of the proper transform of $\boldsymbol{P}_{\boldsymbol{F}_{2}}^{2}$ in the blown-up scheme. For each $\alpha$ in $G L\left(3, \boldsymbol{Q}_{2}\right)$ we denote by $U^{\alpha}$ the $Z_{2}$-scheme such that the generic fiber is equal to $\boldsymbol{P}_{\mathbf{Q}_{2}}^{2}$ and that there exists an isomorphism $U \xrightarrow{\hookrightarrow} U^{\alpha}$ which induces $\alpha^{\wedge}$ on the generic fiber. Then the union $\cup_{\alpha} U^{\alpha}$ over all $\alpha$ in $G L\left(3, \boldsymbol{Q}_{2}\right)$ is patched together to a regular scheme $\mathscr{O}$ with the generic fiber $P_{Q_{2}}^{2}$.

By construction, the action of $G L\left(3, \boldsymbol{Q}_{2}\right)$ on $\boldsymbol{P}_{\mathbf{Q}_{2}}^{2}$ is extended to $\mathscr{X}$. Mumford found the following discrete subgroup $\Gamma$ of $G L\left(3, \boldsymbol{Q}_{2}\right) . \quad \Gamma$ modulo scalar matrices acts on the closed fiber $\mathscr{X}_{0}$ freely and induces a quotient $\mathscr{X} / \Gamma$ as a formal scheme. $\mathscr{X} / \Gamma$ is algebraized to a projective regular scheme over $\boldsymbol{Z}_{2}$, and its generic fiber is the fake projective plane.
$\Gamma$ is contained in the group $\Gamma_{1}$ generated by

$$
\begin{gathered}
\sigma=\left[\begin{array}{ccc}
1 & 0 & \lambda \\
0 & 0 & -1 \\
0 & 1 & -1
\end{array}\right], \quad \tau=\left[\begin{array}{ccc}
0 & 0 & 1 \\
1 & 0 & 1+\lambda \\
0 & 1 & \lambda
\end{array}\right], \\
\rho=\left[\begin{array}{ccc}
1 & 0 & \lambda \\
0 & 1 & -\lambda^{3} / 2 \\
0 & 0 & \lambda^{2} / 2
\end{array}\right] \text { and }-I_{3}=\left[\begin{array}{rrr}
-1 & 0 & 0 \\
0 & -1 & 0 \\
0 & 0 & -1
\end{array}\right],
\end{gathered}
$$

where $\lambda=\zeta+\zeta^{2}+\zeta^{4}=(-1+\sqrt{-7}) / 2$ for $\zeta=\exp (2 \pi i / 7) . \lambda$ is embedded in $Z_{2}$ so that $\lambda=$ (unit) $\cdot 2$, while its complex conjugate $\bar{\lambda}$ is a unit. There exists a homomorphism $\pi: \Gamma_{1} \rightarrow G L\left(2, F_{7}\right)$ and $\Gamma$ is given as the inverse image $\pi^{-1}(S)$ of an arbitrary 2 -Sylow subgroup $S$ of $G L\left(2, \boldsymbol{F}_{7}\right)$.

By the matrices in [Mum, p. 243] which describe $\pi$, we see that the subgroup of $\Gamma_{1}$ generated by $\{\sigma, \tau, \rho\}$ is mapped onto $S L\left(2, \boldsymbol{F}_{7}\right)$ by $\pi$. Since $-I_{3}$ is a scalar matrix, the following change of notation does not affect the construction:

Modification of the Notation. $\Gamma_{1}$ is replaced by its subgroup of index 2 generated by $\{\sigma, \tau, \rho\}$. The homomorphism $\pi$ is replaced by one from the new $\Gamma_{1}$ to $P S L\left(2, \boldsymbol{F}_{7}\right)$. More explicitly, $\pi: \Gamma_{1} \rightarrow P S L\left(2, \boldsymbol{F}_{7}\right)$ is given by

$$
\pi(\sigma)=\left[\begin{array}{ll}
2 & 0 \\
1 & 4
\end{array}\right], \quad \pi(\tau)=\left[\begin{array}{ll}
1 & 0 \\
1 & 1
\end{array}\right] \text { and } \pi(\rho)=\left[\begin{array}{ll}
1 & 4 \\
0 & 1
\end{array}\right]
$$

(see [Mum, p. 243]). The group $\Gamma$ is also replaced by $\pi^{-1}(S)$ for a 2-Sylow subgroup $S$ of $P S L\left(2, \boldsymbol{F}_{7}\right)$. In this case, the set of scalar matrices in $\Gamma_{1}$ is $\left\{\left(\lambda^{2} / 2\right)^{k} I_{3}=(\tau \rho)^{3 k} ; k \in \boldsymbol{Z}\right\}$ (cf. [Mum, p. 241]).

From now on, we use this modified notation.
Let $\Gamma_{0}=\operatorname{Ker} \pi$. Clearly, $\Gamma_{0}$ is a normal subgroup of $\Gamma_{1}$. The quotient $G=\Gamma_{1} / \Gamma_{0}$ is isomorphic to $\operatorname{PSL}\left(2, \boldsymbol{F}_{7}\right)$ and hence is a simple group of order 168. Since $\Gamma_{0}$ modulo scalar matrices is also a torsionfree cocompact subgroup of $P G L\left(3, \boldsymbol{Q}_{2}\right)$, the quotient formal scheme $\mathscr{X} / \Gamma_{0}$ can also be algebraized to a projective regular $Z_{2}$-scheme. We denote the algebraization by $V$. Then the action of $\Gamma_{1}$ on the scheme $\mathscr{X}$ induces an action of $G$ on $V$. Since the scalar matrices in $\Gamma_{1}$ are contained in $\Gamma_{0}$, the induced action is effective. Mumford's fake projective plane is the generic fiber of the quotient $M=V / S$ by the 2-Sylow subgroup $S$ of $G$.

Since $V_{\eta}$ is an unramified cover of degree 8 of Mumford's fake projective plane, the following facts are easily checked.
(1) $V_{\eta}$ is a surface of general type.
(2) $c_{1}^{2}\left(V_{\eta}\right)=72$.
(3) $c_{2}\left(V_{\eta}\right)=24$.
(4) $\chi\left(V_{0}\right)=\chi\left(V_{\eta}\right)=8$.
(5) $q\left(V_{\eta}\right)=0$ ([Mum, p. 238]).
(6) $p_{g}\left(V_{\eta}\right)=7$.

In order to describe the closed fiber of $M$ explicitly, we choose the 2 -Sylow subgroup $S$ of $G=\Gamma_{1} / \Gamma_{0}$ to be the subgroup generated by

$$
\left[\begin{array}{ll}
1 & 1 \\
1 & 2
\end{array}\right] \text { and }\left[\begin{array}{ll}
0 & 1 \\
6 & 0
\end{array}\right]
$$

where we identify $G$ with $\operatorname{PSL}\left(2, \boldsymbol{F}_{7}\right)$ by the isomorphism induced by $\pi$. $S$ is isomorphic to the dihedral group of order 8 . Indeed,

$$
\left[\begin{array}{ll}
1 & 1 \\
1 & 2
\end{array}\right]^{4}=I_{2}, \quad\left[\begin{array}{ll}
0 & 1 \\
6 & 0
\end{array}\right]^{2}=I_{2} \quad \text { and }\left[\begin{array}{ll}
0 & 1 \\
6 & 0
\end{array}\right]\left[\begin{array}{ll}
1 & 1 \\
1 & 2
\end{array}\right]\left[\begin{array}{ll}
0 & 1 \\
6 & 0
\end{array}\right]=\left[\begin{array}{ll}
1 & 1 \\
1 & 2
\end{array}\right]^{-1}
$$

in $\operatorname{PSL}\left(\mathbf{2}, \boldsymbol{F}_{7}\right)$.
We denote by $B$ the proper transform in $\mathscr{X}$ of the closed fiber $\boldsymbol{P}_{F_{2}}^{2} \subset \boldsymbol{P}_{\boldsymbol{Z}_{2}}^{2}=\operatorname{Proj} \boldsymbol{Z}_{2}\left[X_{0}, X_{1}, X_{2}\right] . \quad B$ is an irreducible component of $\mathscr{X}_{0}$ and the projection $p: B \rightarrow \boldsymbol{P}_{F_{2}}^{2}$ is the blowing-up $\boldsymbol{P}_{\boldsymbol{F}_{2}}^{2}$ at the seven $\boldsymbol{F}_{2}$-rational points. We denote by $C(a, b, c)$ the proper transform of the line $a X_{0}+$ $b X_{1}+c X_{2}=0$ on $P_{F_{2}}^{2}$ to $B$ and let $E(a, b, c):=p^{-1}((a, b, c))$ for each triple ( $a, b, c$ ) of 0 or 1 with not all being zero.

The natural morphism from $B$ to the closed fiber $M_{0}=\mathscr{X}_{0} / \Gamma$ can be regarded as the normalization. Actually, we obtain $M_{0}$ by identifying each of suitable seven pairs of $C(a, b, c)$ and $E\left(a^{\prime}, b^{\prime}, c^{\prime}\right)$ in $B$. More precisely, we take $\left\{\rho \sigma^{2} \tau, \tau \rho \sigma \tau, \tau^{2} \rho \tau, \tau^{3} \rho \sigma \tau^{6}, \tau^{4} \rho \sigma^{2} \tau^{5}, \tau^{5} \rho \sigma^{2}, \tau^{6} \rho \sigma^{2} \tau^{6}\right\} \subset \Gamma$ as the set of representatives of $S \backslash\{1\}$. Then each element induces an isomorphism of curves on $B$ as follows:

$$
\begin{aligned}
& \left(\rho \sigma^{2} \tau\right)^{\wedge}: E(0,0,1) \xrightarrow{\rightrightarrows} C(1,1,0) . \\
& (\tau \rho \sigma \tau)^{\wedge}: E(1,0,0) \xrightarrow{\rightarrow} C(1,0,0) \text {. } \\
& \left(\tau^{2} \rho \tau\right)^{\wedge}: E(1,1,0) \xrightarrow{\rightarrow} C(0,1,0) . \\
& \left(\tau^{3} \rho \sigma \tau^{\beta}\right)^{\wedge}: E(1,1,1) \xrightarrow{\rightarrow} C(0,0,1) . \\
& \left(\tau^{4} \rho \sigma^{2} \tau^{5}\right)^{\wedge}: E(0,1,1) \xrightarrow{\rightarrow} C(1,0,1) . \\
& \left(\tau^{5} \rho \sigma^{2}\right)^{\wedge}: E(1,0,1) \xrightarrow{\rightarrow} C(0,1,1) . \\
& \left(\tau^{6} \rho \sigma^{2} \tau^{6}\right)^{\wedge}: E(0,1,0) \xrightarrow{\leftrightarrows} C(1,1,1) .
\end{aligned}
$$

In Figure 1, we explicitly describe how these seven pairs are identified. The three points to which the same symbol among $A, B, \cdots, G$ is attached are identified to a triple point of $M_{0}$. Here, by $\rho \sigma^{2} \tau$, the two rational curves $E(0,0,1)$ and $C(1,1,0)$ are identified in such a way that symbols $A, A^{*}, B$ come to $A^{*}, A, B$, respectively. Consequently, the double curve obtained by this identification has a self-intersection point. Figure 2 indicates the configuration of the double curves on $M_{0}$.

We can check these results by calculating the corresponding action of $\Gamma_{1}$ on the Bruhat-Tits building which is isomorphic to the dual graph of the irreducible components of $\mathscr{X}_{0}$ [Mum, p. 235].

Figure 1

Figure 2
2. Singularities of the quotient surface. Since $V$ is projective and $G$ is finite, the quotient $Y=V / G$ is also a projective $Z_{2}$-scheme. Although $V$ is regular, $Y$ has some singularities, since the action has fixed points. In this section, we study the singularities of $Y$.

Let $\overline{\boldsymbol{Q}}_{2}$ be the algebraic closure of the 2 -adic number field $\boldsymbol{Q}_{2}$. The discrete valuation $v$ of $\boldsymbol{Q}_{2}$ with $v(2)=1$ is uniquely extended to a valuation

$$
v: \overline{\boldsymbol{Q}}_{2} \rightarrow \boldsymbol{Q} \cup\{\infty\}
$$

The non-noetherian valuation ring $\overline{\boldsymbol{Z}}_{2}=\left\{a \in \overline{\boldsymbol{Q}}_{2} ; v(\alpha) \geqq 0\right\}$ is equal to the integral closure of $\boldsymbol{Z}_{2}$ in $\overline{\boldsymbol{Q}}_{2}$. For the maximal ideal $\mathfrak{m}=\left\{a \in \overline{\boldsymbol{Z}}_{2} ; v(a)>0\right\}$, the residue field $\overline{\boldsymbol{Z}}_{2} / \mathfrak{m}$ is equal to the algebraic closure $\overline{\boldsymbol{F}}_{2}$ of the prime field $\boldsymbol{F}_{2}$.

In order to describe the geometric points of $V_{\eta}$ and $Y_{\eta}$, it is convenient to use the $\overline{\boldsymbol{Z}}_{2}$-valued points of the $\boldsymbol{Z}_{2}$-scheme $\mathscr{X}$.

Let $\mathscr{D}:=\mathscr{X}\left(\overline{\boldsymbol{Z}}_{2}\right)$ be the set of $\overline{\boldsymbol{Z}}_{2}$-valued points of $\mathscr{X}$. Since $\overline{\boldsymbol{Q}}_{2}$ is the quotient field of $\overline{\boldsymbol{Z}}_{2}$, we have an injection

$$
\mathscr{D} \rightarrow \mathscr{X}\left(\overline{\boldsymbol{Q}}_{2}\right)=\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right),
$$

where $\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ is the projective plane with the coordinates ( $X_{0}: X_{1}: X_{2}$ ). Hence we use this coordinate system to represent the points of $\mathscr{D}$ through this injection. As we see later, Mumford's fake projective plane is settheoretically the quotient of $\mathscr{D}$ by $\Gamma \subset G L\left(3, \overline{\boldsymbol{Q}}_{2}\right)$.

Let $x: \operatorname{Spec}\left(\overline{\boldsymbol{Z}}_{2}\right) \rightarrow \mathscr{X}$ be a point of $\mathscr{O}$. Then by composing it with the inclusion $\operatorname{Spec}\left(\overline{\boldsymbol{F}}_{2}\right) \hookrightarrow \operatorname{Spec}\left(\overline{\boldsymbol{Z}}_{2}\right)$, we get an $\overline{\boldsymbol{F}}_{2}$-valued point of $\mathscr{B}_{0} \subset \mathscr{X}$. We denote it by $2-\operatorname{red}(x)$. Let $y \in \mathscr{X}$ be the support point of $2-\operatorname{red}(x)$. Then we get the associated local homomorphism $\mathcal{O}_{y, 2} \rightarrow \overline{\boldsymbol{Z}}_{2}$. By this observation, we see that $\mathscr{D}$ is equal to the sum

$$
\bigcup_{y \in \mathscr{Z}_{0}}\left\{x: \mathcal{O}_{y, \mathscr{E}} \rightarrow \bar{Z}_{2} ; x \text { is a local } Z_{2} \text {-homomorphism }\right\}
$$

We would like to know which points of $\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ are in $\mathscr{\mathscr { D }}$. Since $\mathscr{X}_{0}$ is a normal crossing divisor in $\mathscr{X}$, the points of $\mathscr{P}_{0}$ are classified into the following three types: (1) Smooth points of $\mathscr{P}_{0}$. (2) Points lying only on a double curve of $\mathscr{X}_{0}$. (3) Triple points.

Recall that the dual graph which describes the intersections of the components of $\mathscr{X}_{0}$ is known as the Bruhat-Tits building. Each irreducible component $E$ of $\mathscr{X}_{0}$ corresponds to a free $\boldsymbol{Z}_{2}$-module $M \subset \boldsymbol{Q}_{2} X_{0}+\boldsymbol{Q}_{2} X_{1}+\boldsymbol{Q}_{2} X_{2}$ of rank three modulo the equivalence relation $M \sim 2^{k} M$. More explicitly, $\operatorname{Proj} S^{*} M \simeq P_{Z_{2}}^{2}$ for the symmetric algebra $S^{*} M$ is dominated by $\mathscr{X}$, and $E$ is the proper transform of the closed fiber. For the detail, see [Mum, p. 235].
(1) Let $B$ be the irreducible component of $\mathscr{P}_{0}$ which corresponds to the module $M_{0}=Z_{2} X_{0}+Z_{2} X_{1}+Z_{2} X_{2}$. The smooth points of $\mathscr{X}_{0}$ which are contained in $B$ are exactly those points of $\boldsymbol{P}_{F_{2}}^{2}=\operatorname{Proj} \boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right] \subset$ $\operatorname{Proj} \boldsymbol{Z}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ which are not on the seven $\boldsymbol{F}_{2}$-rational lines on it. These lines are given by $\left(X_{0}=0\right),\left(X_{1}=0\right),\left(X_{2}=0\right),\left(X_{0}+X_{1}=0\right)$, $\left(X_{0}+X_{2}=0\right),\left(X_{1}+X_{2}=0\right)$ and $\left(X_{0}+X_{1}+X_{2}=0\right)$. Hence, a point $x=\left(x_{0}: x_{1}: x_{2}\right) \in \boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ is in $\mathscr{D}$ with $2-\operatorname{red}(x)$ in this smooth part if and only if

$$
v\left(x_{0}\right)=v\left(x_{1}\right)=v\left(x_{2}\right)=v\left(x_{0}+x_{1}\right)=v\left(x_{0}+x_{2}\right)=v\left(x_{1}+x_{2}\right)=v\left(x_{0}+x_{1}+x_{2}\right) .
$$

(2) Let $C$ be the double curve which corresponds to the pair $\boldsymbol{Z}_{2} X_{0}+\boldsymbol{Z}_{2} X_{1}+\boldsymbol{Z}_{2} X_{2} / 2 \supset \boldsymbol{Z}_{2} X_{0}+\boldsymbol{Z}_{2} X_{1}+\boldsymbol{Z}_{2} X_{2}$. It can be shown easily that $2-\operatorname{red}(x)$ of a point $x \in \boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ is on $C$ and that it is not a triple point if and only if

$$
v\left(x_{2}\right)-1<v\left(x_{0}\right)=v\left(x_{1}\right)=v\left(x_{0}+x_{1}\right)<v\left(x_{2}\right) .
$$

(3) The triple point $P$ which corresponds to the triple $\boldsymbol{Z}_{2} X_{0}+$ $\boldsymbol{Z}_{2} X_{1} / 2+\boldsymbol{Z}_{2} X_{2} / 2 \supset \boldsymbol{Z}_{2} X_{0}+\boldsymbol{Z}_{2} X_{1}+\boldsymbol{Z}_{2} X_{2} / 2 \supset \boldsymbol{Z}_{2} X_{0}+\boldsymbol{Z}_{2} X_{1}+\boldsymbol{Z}_{2} X_{2}$ is the point $X_{1} / X_{0}=X_{2} / X_{1}=2 X_{0} / X_{2}=0$ of $\operatorname{Spec} Z_{2}\left[X_{1} / X_{0}, X_{2} / X_{1}, 2 X_{0} / X_{2}\right]$ (see [Mum, p. 234]). Then $2-\operatorname{red}(x)$ is equal to $P$ if and only if

$$
v\left(x_{2}\right)-1<v\left(x_{0}\right)<v\left(x_{1}\right)<v\left(x_{2}\right) .
$$

$P G L\left(3, \boldsymbol{Q}_{2}\right)$ acts transitively on the sets of the irreducible components, the double curves and triple points of $\mathscr{P}_{0}$, respectively. Hence we have the following description of $\mathscr{D}$.

Proposition 2.1. Let $x=\left(x_{0}: x_{1}: x_{2}\right)$ be a point of $\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$. Then $x$ is in $\mathscr{D}$ if and only if there exists $\alpha \in G L\left(3, \boldsymbol{Q}_{2}\right)$ such that $\left(y_{0}, y_{1}, y_{2}\right)=$ $\left(x_{0}, x_{1}, x_{2}\right) \alpha$ satisfies either
(i) $v\left(y_{0}\right)=v\left(y_{1}\right)=v\left(y_{2}\right)=v\left(y_{0}+y_{1}\right)=v\left(y_{0}+y_{2}\right)=v\left(y_{1}+y_{2}\right)=v\left(y_{0}+y_{1}+y_{2}\right)$,
(ii) $v\left(y_{2}\right)-1<v\left(y_{0}\right)=v\left(y_{1}\right)=v\left(y_{0}+y_{1}\right)<v\left(y_{2}\right)$ or
(iii) $v\left(y_{2}\right)-1<v\left(y_{0}\right)<v\left(y_{1}\right)<v\left(y_{2}\right)$.

By the above criterion, it is easy to see that any $\boldsymbol{Q}_{2}$-rational point of $\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ is not in $\mathscr{D}$. In fact, we have the following stronger result.

Proposition 2.2. Let $K$ be an arbitrary quadratic extension of $\boldsymbol{Q}_{2}$. If $x_{0}, x_{1}, x_{2}$ are elements of $K$, then the point $\left(x_{0}: x_{1}: x_{2}\right) \in \boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ is not contained in $\mathscr{D}$.

Proof. Let $\alpha$ be an element of $G L\left(3, \boldsymbol{Q}_{2}\right)$ and let $\left(y_{0}, y_{1}, y_{2}\right)=$ $\left(x_{0}, x_{1}, x_{2}\right) \alpha$. Clearly, $y_{0}, y_{1}, y_{2}$ are also in $K$. Let $\mathcal{O}_{K}$ be the integral closure of $\boldsymbol{Z}_{2}$ in $K$. Since $\boldsymbol{Z}_{2}$ is Henselian, $\mathcal{O}_{K}$ is also a discrete valuation
ring. Let $u \mathcal{O}_{K}$ be the maximal ideal of $\mathcal{O}_{K}$. Since the ramification index $e$ and the relative degree $f$ satisfy the relation $e f=\left[K: \boldsymbol{Q}_{2}\right]=2$, we have two possibilities: Namely,
(1) $e=1$ and $f=2$, i.e., $v(u)=1$ and $\mathcal{O}_{K} / u \mathcal{O}_{K}=\boldsymbol{F}_{4}$, or
(2) $e=2$ and $f=1$, i.e., $v(u)=1 / 2$ and $\mathcal{O}_{K} / u \mathcal{O}_{K}=\boldsymbol{F}_{2}$.

We now show that in both cases none of the three conditions in Proposition 2.1 is satisfied. We may assume $y_{0}, y_{1}, y_{2} \in \mathcal{O}_{K}$ and one of them is 1 by dividing them by some $y_{i}$, if necessary. Let $\bar{y}_{0}, \bar{y}_{1}, \bar{y}_{2}$ be the images of $y_{0}, y_{1}, y_{2}$ in $\mathscr{O}_{K} / u \mathscr{O}_{K}$, respectively.

Case (1). $\quad v\left(y_{0}\right)=v\left(y_{1}\right)=v\left(y_{2}\right)=0$ implies $\bar{y}_{0}, \bar{y}_{1}, \bar{y}_{2} \neq 0 . \quad v\left(y_{0}+y_{1}\right)=$ $v\left(y_{0}+y_{2}\right)=v\left(y_{1}+y_{2}\right)=0$ implies that $\bar{y}_{0}, \bar{y}_{1}, \bar{y}_{2}$ are distinct elements of $\boldsymbol{F}_{4}$. Since the sum of the three distinct non-zero elements of $\boldsymbol{F}_{4}$ is zero, we have $v\left(y_{0}+y_{1}+y_{2}\right)>0$. Hence (i) of Proposition 2.1 is impossible. Both (ii) and (iii) are obviously impossible, since $v\left(y_{i}\right)$ 's are integers.

Case (2). (i) and (ii) are impossible, since $v\left(y_{0}\right)=v\left(y_{1}\right)$ and $\mathcal{O}_{K} / u \mathcal{O}_{K} \simeq \boldsymbol{F}_{2}$ imply $v\left(y_{0}+y_{1}\right)>v\left(y_{0}\right)$. (iii) is also impossible, since $v\left(y_{i}\right)$ 's are half integers. q.e.d.

Although $\overline{\boldsymbol{Z}}_{2}$ is neither complete nor noetherian, we have the following:
Lemma 2.3. Let $\left(A, \mathfrak{m}_{A}\right)$ be a local $\boldsymbol{Z}_{2}$-algebra essentially of finite type with $2 \in \mathfrak{m}_{A}$. Then, for the 2-adic completion $i: A \rightarrow A \llbracket 2 \rrbracket$, the induced map

$$
\begin{aligned}
& i^{*}:\left\{f: A \llbracket \mathbf{2} \rrbracket \rightarrow \overline{\boldsymbol{Z}}_{2} ; \text { local } \boldsymbol{Z}_{2} \text {-homomorphism }\right\} \\
& \rightarrow\left\{f: A \rightarrow \overline{\boldsymbol{Z}}_{2} ; \text { local } \boldsymbol{Z}_{2} \text {-homomorphism }\right\}
\end{aligned}
$$

is bijective.
Proof. Let $f, g: A \llbracket 2 \rrbracket \rightarrow \overline{\boldsymbol{Z}}_{2}$ be two local $\boldsymbol{Z}_{2}$-homomorphisms. Suppose that their restrictions to $A$ are equal. Then they induce the same homomorphism $A / 2^{n} A \rightarrow \overline{\boldsymbol{Z}}_{2} / 2^{n} \overline{\boldsymbol{Z}}_{2}$ for every $n>0$. By taking their projective limits, we have a homomorphism $A \llbracket 2 \rrbracket \rightarrow \bar{Z}_{2} \llbracket 2 \rrbracket$. Since the natural homomorphism $\overline{\boldsymbol{Z}}_{2} \rightarrow \overline{\boldsymbol{Z}}_{2} \llbracket 2 \rrbracket$ is injective, $f$ and $g$ are equal. Hence $i^{*}$ is injective. We now show the surjectivity. Let $f: A \rightarrow \overline{\boldsymbol{Z}}_{2}$ be a local $\bar{Z}_{2}$ homomorphism. Since $A$ is essentially of finite type, the image $f(A)$ is contained in a finite extension of $\boldsymbol{Q}_{2}$ and hence it is a finite $\boldsymbol{Z}_{2}$-algebra. Hence it is complete in the 2 -adic topology. Hence the homomorphism $f: A \rightarrow f(A) \hookrightarrow \overline{\boldsymbol{Z}}_{2}$ can be extended to $A \llbracket 2 \rrbracket \rightarrow f(A)$.
q.e.d.

Recall that $\Gamma_{0}$ is a normal subgroup of $\Gamma_{1}$ such that $G=\Gamma_{1} / \Gamma_{0}$ is isomorphic to $\operatorname{PSL}\left(2, \boldsymbol{F}_{7}\right)$. For an element $\alpha$ of $\Gamma_{1}$, we denote by $\alpha^{-}$the
induced automorphism of the $Z_{2}$-scheme $V=\mathscr{E} \mid \Gamma_{0}$.
Proposition 2.4. There exists a natural map

$$
\varphi: \mathscr{D} \rightarrow V\left(\overline{\boldsymbol{Q}}_{2}\right)
$$

such that the action of $\Gamma_{1}$ on $\mathscr{D}$ and $V\left(\overline{\mathbb{Q}}_{2}\right)$ are compatible with this map, i.e., for an arbitrary element $\alpha \in \Gamma_{1}$, the diagram

commutes. Furthermore, the induced map $\bar{\varphi}: \mathscr{D} \mid \Gamma_{0} \rightarrow V\left(\overline{\boldsymbol{Q}}_{2}\right)$ is bijective.
Proof. Note that $V\left(\overline{\boldsymbol{Q}}_{2}\right)=V\left(\overline{\boldsymbol{Z}}_{2}\right)$, since $V$ is proper over $\boldsymbol{Z}_{2}$. By Lemma 2.3, we have natural bijections

$$
\mathscr{D} \simeq \simeq_{y \in \mathcal{F}_{0}}\left\{x: \mathcal{O}_{y, x}^{h} \rightarrow \bar{Z}_{2} ; \text { local } Z_{2} \text {-homomorphism }\right\}
$$

and
where $\mathcal{O}_{y, \mathscr{E}}^{h}$ (resp. $\mathcal{O}_{\bar{y}, \mathscr{x} / \Gamma_{0}}^{h}$ ) is the local ring at $y$ (resp $\bar{y}$ ) of $\mathscr{X}$ (resp. $\mathscr{Z}\left(\Gamma_{0}\right)$ as a formal scheme, i.e., the 2 -adic completion of the usual algebraic local ring. Let $x: \mathcal{O}_{y, \mathscr{E}} \rightarrow \bar{Z}_{2}$ be an element of $\mathscr{D}$. Then, for the image $\bar{y}$ of $y$ in the free quotient $\mathscr{X}_{0} / \Gamma_{0}$, we have a natural isomorphism

We define $\varphi(x)$ to be the composite

$$
\mathcal{O}_{\overline{\bar{z}}, \mathscr{Q} / \Gamma_{0}} \rightarrow \mathcal{O}_{\bar{y}, \mathscr{2} / \Gamma_{0}}^{h} \xrightarrow{\sim} \mathcal{O}_{y, x_{2}}^{h} \xrightarrow{x^{\prime}} \bar{Z}_{2},
$$

where $x^{\prime}$ is the homomorphism which satisfies $i^{*}\left(x^{\prime}\right)=x$ for the embedding $i: \mathcal{O}_{y, \mathscr{\infty}} \rightarrow \mathcal{O}_{y, \mathscr{\infty}}^{h}$. Then it is obvious that $\varphi$ satisfies the assertion of the proposition since $\mathscr{X} / \Gamma_{0}$ is the quotient of the formal scheme $\mathscr{X}$ with respect to a free action. q.e.d.

Now, we study the ramification of the quotient $V_{\eta} \rightarrow(V / H)_{\eta}$ with respect to a subgroup $H \subset G$. We need the following elementary ringtheoretic lemmas.

Lemma 2.5. Let $B$ be a $Z_{2}$-algebra of finite type. Assume that a finite group $G$ acts on $B$ as a $Z_{2}$-algebra, and that a $G$-invariant maximal ideal $\mathfrak{p}$ contains 2. Then, for the local ring $A=B_{p}$, the ring $A^{G}$ of $G$ -
invariant elements of $A$ is essentially of finite type over $\boldsymbol{Z}_{2}$, and $A^{G} \llbracket 2 \rrbracket$ is equal to $A \llbracket 2 \rrbracket^{G}$.

Proof. Since $B$ is of finite type and $G$ is a finite group, the subring $B^{G}$ is also of finite type over $\boldsymbol{Z}_{2}$ and $B$ is finite over $B^{G}$. Let $\mathfrak{p}^{G}=B^{G} \cap \mathfrak{p}$. Then since $\mathfrak{p}$ is $G$-invariant, $B \backslash \mathfrak{p}$ is a $G$-invariant multiplicative set with $(B \backslash \mathfrak{p})^{G}=B^{G} \backslash \mathfrak{p}^{G}$. Since $G$ is finite, $A$ is equal to $\left(B^{G} \backslash \mathfrak{p}^{G}\right)^{-1} B$ and $A^{G}=$ $\left(B^{G}\right)_{p} G$. Hence $A^{G}$ is essentially of finite type and $A$ is finite over $A^{G}$. There is an exact sequence

$$
0 \rightarrow A^{G} \rightarrow A \xrightarrow{\delta} A^{\oplus|G|} / \Delta(A)
$$

of finite $A^{G}$-modules, where $\Delta(A)$ is the diagonal and $\delta(a)=(g a)_{g \in G}$. Since $A^{G} \llbracket 2 \rrbracket$ is flat over $A^{G}$, and since $A \otimes_{A^{G}} A^{G} \llbracket 2 \rrbracket$ is equal to $A \llbracket 2 \rrbracket$, we get $A^{G} \llbracket 2 \rrbracket=A \llbracket 2 \rrbracket^{G}$ by tensoring this exact sequence with $A^{G} \llbracket 2 \rrbracket$. q.e.d.

Lemma 2.6. Let $A$ be a local $\boldsymbol{Z}_{2}$-algebra essentially of finite type with $2 \in \mathfrak{m}_{4}$. Let $\mathfrak{p}$ be a prime ideal of $A$ with $2 \notin \mathfrak{p}$ and $A / \mathfrak{p}$ is finite over $\boldsymbol{Z}_{2}$. Then, for $A^{\prime}=A \llbracket 2 \rrbracket$, we have $A_{\mathfrak{p} A^{\prime}}^{\prime} \llbracket \mathfrak{p} \rrbracket=A_{\mathfrak{p}} \llbracket \mathfrak{p} \rrbracket$.

Proof. Since $A / \mathfrak{p}$ is finite over $\boldsymbol{Z}_{2}$, the finite $A / \mathfrak{p}$-module $\mathfrak{p}^{n} / \mathfrak{p}^{n+1}$ is also a finite $\boldsymbol{Z}_{2}$-module for every $n \geqq 0$. Hence $A / \mathfrak{p}^{n}$ is a finite $\boldsymbol{Z}_{2}$-algebra, and is complete in the 2 -adic topology. Namely, we have $A / \mathfrak{p}^{n}=\left(A / \mathfrak{p}^{n}\right) \llbracket 2 \rrbracket=$ $A^{\prime} / \mathfrak{p}^{n} A^{\prime}$. Since $\left(A / \mathfrak{p}^{n}\right)_{p / p^{n}}=A_{\mathfrak{p}} / \mathfrak{p}^{n} A_{\mathfrak{p}}$ and $\left(A^{\prime} / \mathfrak{p}^{n} A^{\prime}\right)_{p A^{\prime} / \mathfrak{p}^{n} A^{\prime}}=A_{\mathfrak{p} A^{\prime}}^{\prime} / \mathfrak{p}^{n} A_{\mathfrak{p} A^{\prime}}^{\prime}$, we have $A_{\mathfrak{p}} / \mathfrak{p}^{n} A_{\mathfrak{p}}=A_{\mathfrak{p} A^{\prime}}^{\prime} / \mathfrak{p}^{n} A_{\mathfrak{p} A^{\prime}}^{\prime}$. The lemma is just the projective limit with respect to $n$ of this equality.
q.e.d.

Let $H$ be a subgroup of $G=\Gamma_{1} / \Gamma_{0}$, and let $\Gamma_{H}$ be the pull-back $\pi^{-1}(H) \subset \Gamma_{1}$. Let $x$ be a point in $\mathscr{D}$ and let $\bar{x}=\varphi(x) \in V\left(\overline{\boldsymbol{Q}}_{2}\right)$. We denote by $\bar{\Gamma}_{1}, \bar{\Gamma}_{0}$ and $\bar{\Gamma}_{H}$ the images of $\Gamma_{1}, \Gamma_{0}$ and $\Gamma_{H}$ in $P G L\left(3, \boldsymbol{Q}_{2}\right)$ as in Mumford [Mum, p. 240]. Since $\bar{\Gamma}_{H} / \bar{\Gamma}_{0} \simeq H$ and since $\bar{\Gamma}_{0}$ acts freely on $\mathscr{D}$, the isotropy groups

$$
\begin{aligned}
& T\left(x, \bar{\Gamma}_{H}\right)=\left\{\alpha^{\wedge} \in \bar{\Gamma}_{H} ; \alpha^{\wedge}(x)=x\right\} \quad \text { and } \\
& T(\bar{x}, H)=\left\{\alpha^{-} \in H ; \alpha^{-}(\bar{x})=\bar{x}\right\}
\end{aligned}
$$

are isomorphic.
Proposition 2.7. The singularity of the quotient of $\boldsymbol{P}_{\mathbf{Q}_{2}}^{2}$ with respect to $T\left(x, \Gamma_{H}\right)$ at the image of $x$ is formally isomorphic to that of the quotient of $V$ with respect to $T(\bar{x}, H)$ at the image of $\bar{x}$.

Proof. Set $T=T\left(x, \bar{\Gamma}_{H}\right)$ and $\bar{T}=T(\bar{x}, H)$. Let $y$ be the support point of $2-\operatorname{red}(x)$ and let $\bar{y} \in V_{0}$ be the specialization of the support point of $\bar{x}$. Then by Lemma 2.5 , we have

$$
\left(\mathcal{O}_{y, x}\right)^{T} \llbracket 2 \rrbracket=\left(\mathcal{O}_{y, \mathscr{x}}^{h}\right)^{T} \simeq\left(\mathcal{O}_{\bar{y}, V}^{h}\right)^{\bar{T}}=\left(\mathcal{O}_{\bar{y}, V}\right)^{\bar{T}} \llbracket 2 \rrbracket .
$$

Let $\mathfrak{p}$ and $\mathfrak{p}^{\prime}$ be the kernel of the composite homomorphisms

$$
\left(\mathcal{O}_{y, \mathscr{x}}\right)^{T} \rightarrow \mathcal{O}_{y, \mathscr{x}} \xrightarrow{x} \overline{\boldsymbol{Z}}_{2} \quad \text { and } \quad\left(\mathcal{O}_{\bar{y}, V}\right)^{\bar{T}} \rightarrow \mathcal{O}_{\bar{y}, V} \xrightarrow{\bar{x}} \bar{Z}_{2},
$$

respectively. Then $\left(\left(\mathcal{O}_{y, \mathscr{x}}\right)^{T}\right)_{\mathfrak{p}}$ and $\left(\left(\mathcal{O}_{\bar{u}, V}\right)^{\bar{T}}\right)_{p^{\prime}}$ are the local rings of the support points of $x$ and $\bar{x}$, respectively. By Lemma 2.6 and the above equality, we have an isomorphism $\left(\left(\mathcal{O}_{y, \mathscr{x}}\right)^{T}\right)_{p} \llbracket \mathfrak{p} \rrbracket \xrightarrow{\sim}\left(\left(\mathcal{O}_{\bar{y}, V}\right)^{\bar{T}}\right)_{\mathfrak{p}^{\prime}} \llbracket \mathfrak{p}^{\prime} \rrbracket$. q.e.d.

Now, we study the case $H=G$ and hence $\Gamma_{H}=\Gamma_{1}$. We denote by $Y$ the $Z_{2}$-scheme $V / G$. Since $T\left(x, \bar{\Gamma}_{1}\right) \simeq T(\bar{x}, G) \subset G$, each element of $T(x, \bar{\Gamma})$ is of finite order. Mumford [Mum, p. 241] has already shown that every element of $\bar{\Gamma}_{1}$ of finite order is conjugate to one of $\sigma^{i} \tau^{j}$ or $(\rho \tau)^{i}$ for some $0 \leqq i \leqq 2$ and $0 \leqq j \leqq 6$. Since $\{\sigma, \tau\}$ generates a noncommutative group of order 21, they are conjugate to one of

$$
1, \sigma, \sigma^{2}, \tau, \tau^{2}, \cdots, \tau^{8},(\tau \rho),(\tau \rho)^{2} .
$$

Since the fixed points of conjugate elements come to the same points in $Y$, it is sufficient to determine the fixed points of $\sigma, \tau$ and $\tau \rho$ in $\mathscr{X}_{0}$ or $\mathscr{D}$ in order to find out all the ramification points of $f: V \rightarrow Y$.

Before determining the ramification points of $f: V \rightarrow Y$, we have to reformulate some of Mumford's results in a different way.

Remark 2.8. Mumford has shown the following in his paper.
(i) For the component $B$ of $\mathscr{P}_{0}$ which corresponds to the module $M_{0}=Z_{2} X_{0}+Z_{2} X_{1}+Z_{2} X_{2}$, the stabilizer $\left\{\alpha^{\wedge} \in \bar{\Gamma}_{1} ; \alpha^{\wedge}(B)=B\right\}$ is equal to $\bar{\Gamma}_{2}$ which is the group of order 21 generated by $\sigma$ and $\tau$ (cf. [Mum, p. 241]).
(ii) $\bar{\Gamma}_{2}$ acts on the $\boldsymbol{F}_{2}$-rational points on $B$ simply transitively (cf. [Mum, p. 242]).
(iii) In particular, if $\alpha^{\wedge} \in \bar{\Gamma}_{1}$ fixes $B$ and one $\boldsymbol{F}_{2}$-rational point on it, then $\alpha^{\wedge}=1$.

We first determine the fixed points of $\sigma, \tau$ and $\tau \rho$ in the closed fiber $\mathscr{X}_{0}$. We can do so by looking at the corresponding action on the BruhatTits building as follows:

Let $x_{0}$ be a fixed point of $\sigma$ on $\mathscr{X}_{0}$. Then there exists an irreducible component $B^{\prime}$ of $\mathscr{X}_{0}$ which is stable under $\sigma$ and which contains $x_{0}$. Actually if $x_{0}$ is the triple point corresponding to the triple of distinct $\boldsymbol{Z}_{2}$ submodules $M_{0}^{\prime} \supset M_{1}^{\prime} \supset M_{2}^{\prime}$ of $\boldsymbol{Q}_{2} X_{0}+\boldsymbol{Q}_{2} X_{1}+\boldsymbol{Q}_{2} X_{2}$ with $M_{2}^{\prime} \supsetneq 2 M_{0}^{\prime}$, then since $\operatorname{det} \sigma=1$ we have $\sigma\left(M_{i}^{\prime}\right)=M_{i}^{\prime}$ for every $i$. If $x_{0}$ is not triple and is on a double curve of $\mathscr{X}_{0}$, then $\sigma$ fixes the two components of $\mathscr{X}_{0}$ which are
adjacent along the double curve since $\sigma$ is of order three. If $x_{0}$ is not on any double curve, then $\sigma$ stabilizes the unique component which contains $x_{0}$.

Let $\gamma$ be an element of $\bar{\Gamma}_{1}$ with $\gamma^{\wedge}(B)=B^{\prime}$. Then $\left(\gamma \sigma \gamma^{-1}\right)^{\wedge}$ stabilizes $B$. Since the subgroups of order three of $\bar{\Gamma}_{2}$ are mutually conjugate, $\gamma \sigma \gamma^{-1}$ is conjugate to $\sigma$ or $\sigma^{2}$. Hence the fixed points of $\sigma$ in $B^{\prime}$ and $B$ give the same ramification points on $Y_{0}$. It is easy to see that $\sigma$ has just two fixed points on $B$. One of them is on $C(1,0,0)$ and the other is on $E(1,0,0)$, and they are identified by $(\tau \rho \sigma \tau)^{\wedge}$ in $M_{0}$. The point on $C(1,0,0)$ is mapped to the point defined by $X_{1}^{2}+X_{1} X_{2}+X_{2}^{2}=0$ on the line $X_{0}=0$ in $P_{P_{2}}^{2}$ by the natural isomorphism. We denote by $w$ the corresponding ramification point of $Y$. Clearly, $w$ is of degree two and splits into two points in $Y\left(\overline{\boldsymbol{F}}_{2}\right)$.

Since $\tau$ is of order seven, any fixed point of $\tau$ in $\mathscr{X}_{0}$ is on a stabilized component. Let $M_{0}^{\prime}$ be the module associated to a component of $\mathscr{X}_{0}$ stabilized by $\tau$. We may assume $M_{0} \supset M_{0}^{\prime}$ and $2 M_{0} \not \supset M_{0}^{\prime}$. Since the group generated by $\tau$ acts transitively on $\left(M_{0} / 2 M_{0}\right) \backslash\{0\}$, we have $M_{0}^{\prime}=M_{0}$. Hence the fixed points of $\tau$ are in $B$. Later we explicitly determine the fixed points of $\tau$ together with those in $\mathscr{D}$.

Since $\operatorname{det} \tau \rho=\lambda^{2} / 2, \tau \rho$ stabilizes no component of $\mathscr{X}_{0}$. Hence it stabilizes no double curve of $\mathscr{P}_{0}$ since it is of order three. It is easy to see that $P \in B$ is the unique triple point fixed by $\tau \rho$.

The fixed points of $\sigma, \tau$ and $\tau \rho$ in $\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ are calculated easily as follows.

$$
\sigma=\left[\begin{array}{rrr}
1 & 0 & \lambda  \tag{1}\\
0 & 0 & -1 \\
0 & 1 & -1
\end{array}\right], \quad \operatorname{det}\left(t I_{3}-\sigma\right)=t^{3}-1
$$

eigenvalues $1 \omega$ $\omega^{2}$
eigenvectors $\quad(3, \lambda, \lambda)(0,1, \omega)\left(0,1, \omega^{2}\right)$,
where $\omega=(-1+\sqrt{-3}) / 2$.

$$
\tau=\left[\begin{array}{ccc}
0 & 0 & 1  \tag{2}\\
1 & 0 & 1+\lambda \\
0 & 1 & \lambda
\end{array}\right]
$$

$\operatorname{det}\left(t I_{3}-\tau\right)=t^{3}-\lambda t^{2}-(\lambda+1) t-1=(t-\zeta)\left(t-\zeta^{2}\right)\left(t-\zeta^{4}\right)$.
eigenvalues
eigenvectors $\quad\left(1, \zeta, \zeta^{2}\right)\left(1, \zeta^{2}, \zeta^{4}\right)\left(1, \zeta^{4}, \zeta\right)$,
where $\zeta=\exp (2 \pi i / 7)$.

$$
\tau \rho=\left[\begin{array}{ccc}
0 & 0 & \lambda^{2} / 2  \tag{3}\\
1 & 0 & 0 \\
0 & 1 & 0
\end{array}\right], \quad \operatorname{det}\left(t I_{3}-\tau \rho\right)=t^{3}-\lambda^{2} / 2,
$$

eigenvalues $\quad \varepsilon \quad \omega \varepsilon \quad \omega^{2} \varepsilon$
eigenvectors $\quad\left(1, \varepsilon, \varepsilon^{2}\right)\left(1, \omega \varepsilon, \omega^{2} \varepsilon^{2}\right) \quad\left(1, \omega^{2} \varepsilon, \omega \varepsilon^{2}\right)$,
where $\varepsilon=\left(\lambda^{2} / 2\right)^{1 / 3}$.
In case (1), since every component of the eigenvectors are in $\boldsymbol{Q}_{2}(\sqrt{-7})$ or $\boldsymbol{Q}_{2}(\sqrt{-3})$, the fixed points of $\sigma$ in $\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ are outside $\mathscr{D}$ by Proposition 2.2.

In case (2), set $\widetilde{q}=\left(1, \zeta, \zeta^{2}\right)$. Note that $\sigma^{\wedge}(\widetilde{q})=\left(1, \zeta^{2}, \zeta^{4}\right)$ and $\left(\sigma^{\wedge}\right)^{2}(\widetilde{q})=$ $\left(1, \zeta^{4}, \zeta\right)$. Let $\zeta_{0}$ be the image of $\zeta$ in $\boldsymbol{Z}_{2}(\zeta) /(2) \simeq \boldsymbol{F}_{8}$. Then since $\zeta_{0} \in \boldsymbol{F}_{8} \backslash \boldsymbol{F}_{4}$, we see that $1+\zeta_{0}, 1+\zeta_{0}{ }^{2}, \zeta_{0}+\zeta_{0}{ }^{2}$ and $1+\zeta_{0}+\zeta_{0}{ }^{2}$ are not zero. This implies that $v(1)=v(\zeta)=v\left(\zeta^{2}\right)=v(1+\zeta)=v\left(1+\zeta^{2}\right)=v\left(\zeta+\zeta^{2}\right)=v\left(1+\zeta+\zeta^{2}\right)=0$. Hence $\widetilde{q}$ is a point of $\mathscr{D}$ by Proposition 2.1. We denote by $q$ the image $f \circ \varphi(\widetilde{q}) \in Y\left(\overline{\boldsymbol{Q}}_{2}\right)$.

Since 2 -red $(\widetilde{q})$ is a smooth point of $\mathscr{X}_{0}$ and is on the component $B$, the isotropy group $T\left(\widetilde{q}, \bar{\Gamma}_{1}\right)$ is a subgroup of $\bar{\Gamma}_{2}$ by Remark 2.8. Since $\sigma$ does not fix $\widetilde{q} \in \mathscr{D}$, we have $T\left(\widetilde{q}, \bar{\Gamma}_{1}\right)=\langle\tau\rangle$. As we see later in Remark 2.10, the linear map $\tau$ is given locally at $\tilde{q}$ by $\left(y_{1}, y_{2}\right) \mapsto\left(\zeta y_{1}, \zeta^{3} y_{2}\right)$. Hence the singularity of the quotient at this point is the cyclic quotient singularity of type (7,3). By Proposition 2.7, the singularity of $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$ at $q$ is also a cyclic quotient singularity of type ( 7,3 ).

These $\tau$-invariant points of $\boldsymbol{P}^{2}\left(\overline{\boldsymbol{Q}}_{2}\right)$ are $\boldsymbol{Q}_{2}(\zeta)$-valued and they are identified to $q$ in $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$ by $\sigma$. Since the action of $\sigma$ on these three points is compatible with the automorphism of $\boldsymbol{Q}_{2}(\zeta)$ defined by $\zeta \mapsto \zeta^{2}$, we see that $q$ is a $\boldsymbol{Q}_{2}$-valued point. Since $Y$ is proper over $\boldsymbol{Z}_{2}$, there exists a $\boldsymbol{Z}_{2}$-valued point $\bar{q}$ : Spec $\boldsymbol{Z}_{2} \rightarrow Y$ such that $\bar{q}(\eta)=q$. We see easily that $\bar{q}(0) \in Y_{0}$ is also a cyclic quotient singularity of type (7,3). We can see similarly that the fixed points of $\tau$ on $B$ are only $\left(1, \zeta_{0}, \zeta_{0}{ }^{2}\right),\left(1, \zeta_{0}{ }^{2}, \zeta_{0}{ }^{4}\right)$ and $\left(1, \zeta_{0}{ }^{4}, \zeta_{0}\right)$. Since $B$ is the only component of $\mathscr{X}_{0}$ stabilized by $\tau$, we see that $\bar{q} \subset Y$ is the unique ramification locus given by $\tau$.

Finally in case (3), set $\widetilde{p}_{0}=\left(1, \varepsilon, \varepsilon^{2}\right), \widetilde{p}_{1}=\left(1, \omega \varepsilon, \omega^{2} \varepsilon^{2}\right)$ and $\widetilde{p}_{2}=$ $\left(1, \omega^{2} \varepsilon, \omega \varepsilon^{2}\right)$. Since $v\left(\lambda^{2} / 2\right)=1$, we have $v(\varepsilon)=1 / 3$, while $v(\omega)=0$. Hence these points are in $\mathscr{D}$ by Proposition 2.1. In this case, 2 -red $\left(\widetilde{p}_{i}\right)$ 's are the same triple point $P \in \mathscr{E}_{0}$. At this point $P$, the three components of $\mathscr{B}_{0}$ which correspond to $\boldsymbol{Z}_{2} X_{0}+\boldsymbol{Z}_{2} X_{1} / 2+\boldsymbol{Z}_{2} X_{2} / 2, \boldsymbol{Z}_{2} X_{0}+\boldsymbol{Z}_{2} X_{1}+\boldsymbol{Z}_{2} X_{2} / 2$ and $\boldsymbol{Z}_{2} X_{0}+\boldsymbol{Z}_{2} X_{1}+\boldsymbol{Z}_{2} X_{2}$ meet together. In particular, the component $B$ contains $P$. Suppose $\alpha^{\wedge} \in \bar{\Gamma}_{1}$ fixes $P$. Then since $\tau \rho$ cyclically permutes
the three components, $(\tau \rho)^{-i} \alpha^{\wedge}$ stabilize $B$ for $i=0,1$ or 2 . By (iii) of Remark 2.8, we get $\alpha^{\wedge}=(\tau \rho)^{i}$. Since the isotropy group of $\widetilde{p}_{i}$ 's are contained in that of $P$, we have $T\left(\tilde{p}_{i}, \bar{\Gamma}_{1}\right)=\langle\tau \rho\rangle$.

No $\alpha \in \bar{\Gamma}_{1}$ maps $\widetilde{p}_{i}$ to another $\tilde{p}_{j}$ since $\alpha^{\wedge}\left(\widetilde{p}_{i}\right)=\widetilde{p}_{j}$ implies $\alpha \in\langle\tau \rho\rangle$. Hence, the points $\tilde{p}_{0}, \tilde{p}_{1}, \tilde{p}_{2}$ are mapped to distinct points in $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$. Let them be $p_{0}, p_{1}$ and $p_{2}$, respectively. As in case (2), we see that $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$ has cyclic quotient singularities of type $(3,2)$ at these points.

The points $\widetilde{p}_{0}, \widetilde{p}_{1}, \widetilde{p}_{2}$ are solutions of the system of equations $\left(X_{1} / X_{0}\right)=$ $\left(X_{2} / X_{1}\right)=\left(\varepsilon^{3} X_{0} / X_{2}\right)$. Since the local ring of $\mathscr{X}$ at $P$ is $Z_{2}\left[X_{1} / X_{0}, X_{2} / X_{1}\right.$, $\left.\varepsilon^{3} X_{0} / X_{2}\right]_{\mathfrak{m}}$ for the maximal ideal $\mathfrak{m}=\left(X_{1} / X_{0}, X_{2} / X_{1}, \varepsilon^{3} X_{0} / X_{2}\right)$, the equations give a $Z_{2}[\varepsilon]$-valued point $\bar{p}$ of $Y$ such that $\bar{p}(0)=P$ and that the image of $\bar{p}(\eta)$ in $Y$ is a $\boldsymbol{Q}_{2}(\varepsilon)$-valued point which splits into the three points $p_{0}, p_{1}, p_{2}$ in $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$. Since $P$ is the unique fixed point of $\tau \rho$ in $\mathscr{P}_{0}$, we see that $\bar{p}$ is the unique ramification locus of $f: V \rightarrow Y$ caused by $\tau \rho$.

Thus we conclude:
Theorem 2.9. The morphism $f: V \rightarrow Y$ is ramified along $\bar{q}, \bar{p}$ and at the point $w \in Y_{0}$ of degree two. The restriction to the geometric fibers $f_{\overline{\mathbf{Q}}_{2}}: V\left(\overline{\boldsymbol{Q}}_{2}\right) \rightarrow Y\left(\overline{\boldsymbol{Q}}_{2}\right)$ is ramified at the point $p_{0}, p_{1}, p_{2}$ and $q$. $p_{0}, p_{1}$ and $p_{2}$ (resp. q) are cyclic quotient singularities of type (3,2) (resp. of type (7, 3)).

Remark 2.10. Let $R$ be the étale finite ring extension $\boldsymbol{Z}_{2}[\zeta, \omega]$ of $\boldsymbol{Z}_{2}$. We can describe the minimal resolution of the singularities along $\bar{q}$ and $\bar{p}$ after the étale base extension $Y_{R} \rightarrow \operatorname{Spec} R$ of $Y \rightarrow \operatorname{Spec} \boldsymbol{Z}_{2}$ as follows:

By the coordinate change

$$
\left(Y_{0}, Y_{1}, Y_{2}\right):=\left(X_{0}, X_{1}, X_{2}\right)\left[\begin{array}{lll}
1 & \zeta & \zeta^{2} \\
1 & \zeta^{2} & \zeta^{4} \\
1 & \zeta^{4} & \zeta
\end{array}\right]^{-1}
$$

of $P_{R}^{2}, \tau$ is diagonalized as

$$
\left[\begin{array}{lll}
\zeta & 0 & 0 \\
0 & \zeta^{2} & 0 \\
0 & 0 & \zeta^{4}
\end{array}\right]
$$

and the eigenvectors are $(1,0,0),(0,1,0)$ and $(0,0,1)$. Hence the local ring of $Y_{R}$ at $\bar{q}(0)$ is formally isomorphic to the localization of the ring of invariants $R\left[Y_{1} / Y_{0}, Y_{2} / Y_{0}\right]^{\tau}$ in the polynomial ring $R\left[Y_{1} / Y_{0}, Y_{2} / Y_{0}\right]$ with respect to the action of $\tau$ defined by $Y_{1} / Y_{0} \mapsto \zeta Y_{1} / Y_{0}$ and $Y_{2} / Y_{0} \mapsto \zeta^{3} Y_{2} / Y_{0}$. One can resolve it minimally by the standard method. For any geometric
fiber, the exceptional set is a chain of nonsingular rational curves with the self-intersection numbers $-3,-2,-2$.

The local ring of $Y_{R}$ at $\bar{p}(0)$ is formally isomorphic to the localization of the ring of invariants $R\left[X_{1} / X_{0}, X_{2} / X_{1}, \varepsilon^{3} X_{0} / X_{2}\right]^{\tau \rho} \subset R\left[X_{1} / X_{0}, X_{2} / X_{1}, \varepsilon^{3} X_{0} / X_{2}\right]$ with respect to the automorphism $\tau \rho$ given by $X_{1} / X_{0} \mapsto X_{2} / X_{1}, X_{2} / X_{1} \mapsto$ $\varepsilon^{3} X_{0} / X_{2}, \varepsilon^{3} X_{0} / X_{2} \mapsto X_{1} / X_{0}$. Note that $\varepsilon^{3}=\lambda^{2} / 2$ is a generator of the maximal ideal of the discrete valuation ring $R$. By the coordinate change

$$
\left(T_{0}, T_{1}, T_{2}\right)=\left(X_{1} / X_{0}, X_{2} / X_{1}, \varepsilon^{3} X_{0} / X_{2}\right)\left[\begin{array}{ccc}
1 & 1 & 1 \\
1 & \omega^{2} & \omega \\
1 & \omega & \omega^{2}
\end{array}\right],
$$

we have

$$
\tau \rho=\left[\begin{array}{ccc}
1 & 0 & 0 \\
0 & \omega & 0 \\
0 & 0 & \omega^{2}
\end{array}\right]
$$

Then the ring of invariants is $R\left[T_{0}, T_{1}^{3}, T_{2}^{3}, T_{1} T_{2}\right]$ with the relation $T_{0}^{3}+T_{1}^{3}+T_{2}^{3}-3 T_{0} T_{1} T_{2}=27 \varepsilon^{3}$. We see easily that this is a complete intersection of a regular ring. In particular, this is a Gorenstein ring. This singularity is resolved by the blowing up along the prime ideal $\left(T_{1}^{3}, T_{2}^{3}, T_{1} T_{2}\right)$. For the geometric fiber $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$, this is the blowing-up at $\left\{p_{0}, p_{1}, p_{2}\right\}$. Since these are cyclic quotient singularities of type (3, 2), this blowing-up gives the minimal resolution of these singular points and each exceptional set is the union of two nonsingular rational curves with the self-intersection numbers -2 intersecting each other at one point.

Thus we minimally resolved the singularities of $Y_{B}$ along $\bar{q}$ and $\bar{p}$. Since this resolution is canonical, it descends to a scheme $Y^{\prime}$ over $\boldsymbol{Z}_{2}$. Clearly, $Y^{\prime}\left(\overline{\boldsymbol{Q}}_{2}\right)$ is the minimal resolution of $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$.
3. The plurigenera of the quotient surface. In this section, we study pluri-canonical line bundles on $V$ and its quotients.

The component $B$ of $\mathscr{X _ { 0 }}$ is a smooth rational surface, and the fourteen rational curves $C(a, b, c)$ 's and $E(a, b, c)$ 's form a divisor $A=\cup_{a, b, c}(C(a, b, c) \cup$ $E(a, b, c))$ with only normal crossings in $B$. For the unramified covering $\mathscr{X}_{0} \rightarrow V_{0}$, we denote by $B_{1}, C(a, b, c)_{1}, E(a, b, c)_{1}, P_{1}$ and $A_{1}$ the image of $B, C(a, b, c), E(a, b, c), P$ and $A$ in $V_{0}$, respectively. Note that the fixed point $P \in \mathscr{Z}_{0}$ of $\tau \rho$, is the intersection point of $C(0,0,1)$ and $E(1,0,0)$. One can check that $B_{1}$ has no self-intersection. Hence $B_{1}$ is isomorphic to $B$.

From now on, we mainly treat $V$ and its quotient with respect to a
subgroup of $G$. Hence, for simplicity, we denote also by $\sigma, \tau, \rho$ their images in $G$. For an element $\alpha \in G$, we denote by $\alpha^{-}$the associated automorphism of $V$ as in Section 2.

Since $M_{0}=V_{0} / S$ consists of only one irreducible component, we have

$$
V_{0}=\bigcup_{\alpha \in S} B_{\alpha} \quad \text { where } \quad B_{\alpha}=\alpha^{-}\left(B_{1}\right) .
$$

Here $B_{\alpha}$ 's cross each other normally and the normalization $\widetilde{V}_{0}$ is equal to the disjoint union $\amalg_{\alpha \in S} B_{\alpha}$. Let $\varphi: \widetilde{V}_{0} \rightarrow V_{0}$ be the natural morphism.

Since the induced action of $G$ on the set of double curves is transitive, and since the stabilizer of the double curve $D_{1}=C(1,0,0)_{1}$ is $\left\{1, \sigma, \sigma^{2}\right\}$, we see that the union $D$ of the double curves is

$$
D=\underset{\beta \in G / \sigma\rangle}{\cup} D_{\beta},
$$

where $G /\langle\sigma\rangle$ is the set of left cosets $\{\langle\sigma\rangle g ; g \in G\}$ and $D_{\beta}:=\beta^{-}\left(D_{1}\right)$.
Similarly, the stabilizer of $P_{1}$ is $\left\{1, \tau \rho,(\tau \rho)^{2}\right\}$ and

$$
\left\{P_{\mu}=\mu^{-}\left(P_{1}\right) ; \mu \in G /\langle\tau \rho\rangle\right\}
$$

is the set of the triple points of $V_{0}$. Note that the set of $\boldsymbol{F}_{2}$-rational points of $V_{0}$ is exactly equal to this set.

For the union $D$ of the double curves of $V_{0}$, let $\delta: \widetilde{D} \rightarrow V_{0}$ be the natural morphism from the normalization $\widetilde{D}=\amalg_{\beta \in G /\langle o\rangle} D_{\beta}$ of $D$ to $V_{0}$.

Since the double curves arise from the identification of ( -1 )-curves and (-2)-curves [Mum, p. 236], there exist morphisms $\varepsilon, \gamma: \widetilde{D} \rightarrow \widetilde{V}_{0}$ such that $\varepsilon\left(D_{\beta}\right)^{2}=-1$ and $\gamma\left(D_{\beta}\right)^{2}=-2$ for every component $D_{\beta}$ of $\widetilde{D}$ and $\varphi \circ \varepsilon=\varphi \circ \gamma=\delta$. The union $\varepsilon(\widetilde{D}) \cup \gamma(\widetilde{D})$ is equal to $\amalg_{\alpha \in S} A_{\alpha}$, where $A_{\alpha}=$ $\alpha^{-}\left(A_{1}\right) \subset B_{\alpha}$.

For any line bundle $L$ on $V_{0}$, the following diagram is exact:

$$
H^{0}\left(V_{0}, L\right) \xrightarrow{\varphi *} H^{0}\left(\tilde{V}_{0}, \varphi^{*} L\right) \xrightarrow[r^{*}]{\stackrel{\varepsilon^{*}}{\longrightarrow}} H^{0}\left(\widetilde{D}, \delta^{*} L\right)
$$

For an equidimensional Gorenstein scheme $Z$, we denote by $\omega_{z}$ its canonical invertible sheaf. As is well known for varieties with normal crossing singularities, we have

$$
\varphi^{*} \omega_{V_{0}}=\omega_{\tilde{V}_{0}}(\varepsilon(\widetilde{D}) \cup \gamma(\widetilde{D}))=\bigoplus_{\alpha \in S} \omega_{B_{\alpha}}\left(A_{\alpha}\right)
$$

Hence we get the exact diagram

$$
\begin{equation*}
H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes m}\right) \rightarrow \underset{\alpha \in S}{ } H^{0}\left(B_{\alpha}, \omega_{B_{\alpha}}^{\otimes m}\left(m A_{\alpha}\right)\right) \underset{r^{*}}{\stackrel{\varepsilon^{*}}{\rightrightarrows}} H^{0}\left(\widetilde{D}, \delta^{*} \omega_{V_{0}}^{\otimes m}\right) \tag{1}
\end{equation*}
$$

for every integer $m$.
On the other hand, $\bigoplus_{\alpha \in S} \varphi_{*} \mathcal{O}_{B_{\alpha}}\left(-A_{\alpha}\right)$ is equal to the ideal $I_{D} \subset \mathcal{O}_{V_{0}}$
defining $D$. Hence by the projection formula, we have

$$
\omega_{V_{0}}^{\otimes m} \otimes I_{D}=\bigoplus_{\alpha \in S} \varphi_{*} \omega_{B_{\alpha}}^{\otimes m}\left((m-1) A_{\alpha}\right)
$$

Hence we get an exact sequence of $\mathcal{O}_{V_{0}}$-modules

$$
\begin{equation*}
0 \rightarrow \bigoplus_{\alpha \in S} \varphi_{*} \omega_{B_{\alpha}}^{\otimes m}\left((m-1) A_{\alpha}\right) \rightarrow \omega_{V_{0}}^{\otimes m} \rightarrow \omega_{V_{0}}^{\otimes m} \otimes \mathcal{O}_{D} \rightarrow 0 \tag{2}
\end{equation*}
$$

Now we analyze the sections of $\omega_{B}^{\otimes m}(m A)$ and $\omega_{B}^{\otimes m}((m-1) A)$ more precisely.

For the projective plane $P_{F_{2}}^{2}$ with the homogeneous coordinate system ( $X_{0}: X_{1}: X_{2}$ ), we set $y=X_{0} / X_{2}$ and $z=X_{1} / X_{2}$. Then the rational 2-form $\omega_{0}=(d y \wedge d z) / y z$ vanishes nowhere and has a pole of order one along the divisor $\left(X_{0} X_{1} X_{2}=0\right)$. Let $p^{*} \omega_{0}$ be the pull-back of $\omega_{0}$ with respect to the natural morphism $p: B \rightarrow \boldsymbol{P}_{F_{2}}^{2}$. Then, the divisor $\left(p^{*} \omega_{0}\right)$ is equal to

$$
\begin{aligned}
E(1,1,1)-C(1,0,0)- & C(0,1,0)-C(0,0,1) \\
& -E(1,0,0)-E(0,1,0)-E(0,0,1)
\end{aligned}
$$

Hence $p^{*} \omega_{0}$ is a section of $\omega_{B}(A)$ with the zero divisor

$$
\begin{aligned}
F_{0}=C(1,1,0)+ & C(1,0,1)+C(0,1,1)+C(1,1,1) \\
& +E(1,1,0)+E(1,0,1)+E(0,1,1)+2 E(1,1,1)
\end{aligned}
$$

Let $F$ be a divisor on $B$ which is linearly equivalent to $F_{0}$. Then the images $p\left(F_{0}\right)$ and $p(F)$ in $P_{F_{2}}^{2}$ are also linearly equivalent. Since $p\left(F_{0}\right)=\left(u_{0}=0\right)$ for $u_{0}=\left(X_{0}+X_{1}\right)\left(X_{0}+X_{2}\right)\left(X_{1}+X_{2}\right)\left(X_{0}+X_{1}+X_{2}\right)$, we see that $p(F)$ is equal to $(f=0)$ for a homogeneous quartic polynomial $f \in \boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$.

Since $p^{*}\left(u_{0}=0\right)-F_{0}=\sum_{a, b, c} E(a, b, c)$ should be equal to $p^{*}(f=0)-F$, the divisor $(f=0) \subset \boldsymbol{P}_{F_{2}}^{2}$ contains all the seven $\boldsymbol{F}_{2}$-rational points of $\boldsymbol{P}_{F_{2}}^{2}$. Conversely, if $f$ is a quartic homogeneous polynomial with $f(a, b, c)=0$ for all triple $(a, b, c)$ of 0 or 1 , then $p^{*}(f=0)-\sum_{a, b, c} E(a, b, c)$ is effective and linearly equivalent to $F_{0}$. Hence $\left(f / u_{0}\right) p^{*} \omega_{0}$ is a section of $\omega_{B}(A)$.

Thus the space of section of $\omega_{B}(A)$ is described as

$$
\begin{equation*}
H^{0}\left(\omega_{B}(A)\right)=\left\{\frac{f}{u_{0}}\left(\frac{d y}{y} \wedge \frac{d z}{z}\right)\right\}, \tag{3}
\end{equation*}
$$

where $f$ runs over the homogeneous polynomials in $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ of degree 4 such that $f(a, b, c)=0$ if $a, b, c=0$ or 1 .

Similarly for general $m \in \boldsymbol{Z}$, we get the following:

$$
\begin{equation*}
H^{0}\left(\omega_{B}^{\otimes m}(m A)\right)=\left\{\frac{f}{u_{0}^{m}}\left(\frac{d y}{y} \wedge \frac{d z}{z}\right)^{\otimes m}\right\} \tag{4}
\end{equation*}
$$

where $f$ runs over the homogeneous polynomials in $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ of degree $4 m$ which has zero of multiplicity at least $m$ at each of the seven $\boldsymbol{F}_{2}$ rational points of $\boldsymbol{P}_{\boldsymbol{F}_{2}}^{2}$.

Let $\omega=\left(f / u_{0}^{m}\right)(d y / y \wedge d z / z)^{\otimes m}$ be an element of $H^{0}\left(\omega_{B}^{\otimes m}(m A)\right)$. Then $\omega$ is in $H^{0}\left(\omega_{B}^{\otimes m}((m-1) A)\right)$ if and only if $f$ has the factor $u=X_{0} X_{1} X_{2}\left(X_{0}+\right.$ $\left.X_{1}\right)\left(X_{0}+X_{2}\right)\left(X_{1}+X_{2}\right)\left(X_{0}+X_{1}+X_{2}\right)$ and $f$ has zero of multiplicity at least $m+1$ at every $\boldsymbol{F}_{2}$-rational point of $\boldsymbol{P}_{\boldsymbol{F}_{2}}^{2}$. Since $u$ has zeros of multiplicity three at these points, we see that

$$
\begin{equation*}
H^{0}\left(\omega_{B}^{\otimes m}((m-1) A)\right)=\left\{\frac{u g}{u_{0}^{m}}\left(\frac{d y}{y} \wedge \frac{d z}{z}\right)^{\otimes m}\right\} \tag{5}
\end{equation*}
$$

where $g$ runs over the homogeneous polynomials in $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ of degree $4 m-7$ which has zeros of multiplicity at least $m-2$ at the seven $\boldsymbol{F}_{2}$ rational points of $\boldsymbol{P}_{F_{2}}^{2}$.

Let $m$ be an integer greater than one. Since $c_{1}{ }^{2}\left(V_{\eta}\right)=72$ and $\chi\left(\mathcal{O}_{V_{\eta}}\right)=8$, we have $P_{m}\left(V_{\eta}\right)=\chi^{0}\left(\omega_{V_{\eta}}^{\otimes m}\right)=36 m(m-1)+8$ by the plurigenus formula for surfaces of general type. Hence $H^{0}\left(V, \omega_{V}^{\otimes m}\right)$ is a free $Z_{2}$ module of rank $36 m(m-1)+8$. By Grothendieck's base change theorem, we have a natural injection

$$
i_{m}: H^{0}\left(V, \omega_{V}^{\otimes m}\right) \underset{Z_{2}}{\otimes} \boldsymbol{F}_{2} \hookrightarrow H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes m}\right)
$$

More generally, let $H$ be a subgroup of $G$ acting freely on $V$ and let $V^{\prime}=V / H$. Then we have an injection

$$
i_{m}^{\prime}: H^{0}\left(V^{\prime}, \omega_{V}^{\otimes m}\right) \otimes_{Z_{2}}^{\otimes} \boldsymbol{F}_{2} \hookrightarrow H^{\circ}\left(V_{0}^{\prime}, \omega_{V_{0}^{( }}^{\otimes m}\right) .
$$

Note that the left hand side is of dimension $(36 m(m-1)+8) /|H|$, since $V_{\eta}^{\prime}$ is also of general type.

PROPOSITION 3.1. The above homomorphisms $i_{m}$ and $i_{m}^{\prime}$ are isomorphisms for $m=2$ and 3 .

Proof. We give the proof only for $i_{m}$, since the proof for general $i_{m}^{\prime}$ is similar. Suppose $m=2$. By (5), we have

$$
H^{0}\left(\omega_{B}^{\otimes_{B}^{2}}(A)\right)=\left\{\frac{\left(a X_{0}+b X_{1}+c X_{2}\right) u}{u_{0}{ }^{2}}\left(\frac{d y}{y} \wedge \frac{d z}{z}\right)^{\otimes 2} ; a, b, c \in \boldsymbol{F}_{2}\right\}
$$

This is obviously three-dimensional. Hence $\bigoplus_{\alpha \in S} H^{\circ}\left(\omega_{B_{\alpha}}^{\otimes_{2}^{2}}\left(A_{\alpha}\right)\right)$ is of dimension $8 \times 3=24$. On the other hand, $V_{0}$ has fifty-six $\boldsymbol{F}_{2}$-rational points $\left\{P_{\mu}\right\}_{\mu \in G /\langle\tau \rho\rangle}$. Hence there exists a natural homomorphism

$$
\begin{equation*}
j_{2}: H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 2}\right) \rightarrow \underset{\mu \in \Theta\langle\langle\tau\rangle}{ } \oplus_{V_{2}}^{\otimes 2}\left(P_{\mu}\right) . \tag{6}
\end{equation*}
$$

Here the right hand side is an $\boldsymbol{F}_{2}$-vector space of dimension 56. Hence
it suffices to show that the kernel Ker $j_{2}$ is contained in $\bigoplus_{\alpha \in S} H^{0}\left(\omega_{B_{\alpha}}^{\otimes 2}\left(A_{\alpha}\right)\right)$, because then the dimension of $H^{\circ}\left(V_{0}, \omega_{V_{0}}^{\otimes 2}\right)$ is at most $24+56=80$ which is the rank of $H^{0}\left(V, \omega_{V}^{\otimes^{2}}\right)$.

Let $\omega$ be an element of $\operatorname{Ker} j_{2}$. We have to show that $\left.\omega\right|_{D_{\beta}}=0$ on each double curve $D_{\beta}$. Set $M_{\beta}=\left.\delta^{*} \omega_{V_{0}}\right|_{D_{\beta}}$. Since $\left.\delta^{*} \omega_{V_{0}}\right|_{D_{\beta}}=\left.\gamma^{*} \omega_{B_{\alpha}}\left(A_{\alpha}\right)\right|_{D_{\beta}}$ for some $\alpha \in S$, and since $\gamma\left(D_{\beta}\right)$ is a nonsingular rational curve with $\gamma\left(D_{\beta}\right)^{2}=-2$, we have

$$
\operatorname{deg} M_{\beta}=\left.\operatorname{deg} \omega_{B_{\alpha}}\right|_{r\left(D_{\beta}\right)}+\gamma\left(D_{\beta}\right) \cdot A_{\alpha}=0+1=1
$$

Since $D_{\beta} \simeq \boldsymbol{P}^{1}\left(\boldsymbol{F}_{2}\right)$ has three $\boldsymbol{F}_{2}$-rational points and $\omega$ is zero there, $\left.\omega\right|_{D_{\beta}} \in H^{0}\left(M_{\beta}^{\otimes 2}\right)$ should be zero.

We now consider the case $m=3$. By (5), $H^{0}\left(\omega_{B}^{\otimes 3}(2 A)\right)$ is isomorphic to the module of homogeneous quintic polynomials which have zeros at all the seven $\boldsymbol{F}_{2}$-rational points of $\boldsymbol{P}_{\boldsymbol{F}_{2}}^{2}$. It is easy to see that this is of dimesion $21-7=14$. Hence $\bigoplus_{\alpha \in S} H^{0}\left(\omega_{B_{\alpha}}^{\otimes 3}\left(2 A_{\alpha}\right)\right)$ is of dimension $8 \times 14=112$. Let $L$ be the kernel of the homomorphism

$$
\begin{equation*}
j_{3}: H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 3}\right) \rightarrow \underset{\mu \in G /\langle\tau \rho\rangle}{ } \omega_{V_{0}}^{\otimes 3}\left(P_{\mu}\right) \simeq \boldsymbol{F}_{2}^{\oplus 58} \tag{7}
\end{equation*}
$$

Clearly, $L$ is of codimension at most 56 in $H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 3}\right)$. Let $D_{\beta}$ be a double curve of $V_{0}$, and let $0,1, \infty$ be its $\boldsymbol{F}_{2}$-rational points. We consider the restriction map $L \rightarrow H^{0}\left(M_{\beta}^{\otimes 3}\right)$. Since $\operatorname{deg} M_{\beta}^{\otimes 3}=3$ and since each element $\omega \in L$ has zeros at $\{0,1, \infty\}$, the image of this map is in $H^{0}\left(M_{\beta}^{\otimes 3}(-0-1-\infty)\right) \simeq \boldsymbol{F}_{2}$. Hence the kernel of the natural homomorphism

$$
\begin{equation*}
L \rightarrow \underset{\beta \in G / / \sigma\rangle}{\oplus} H^{0}\left(M_{\beta}^{\otimes 3}(-0-1-\infty)\right)=\boldsymbol{F}_{2}^{\oplus \text { sв }} \tag{8}
\end{equation*}
$$

is of codimension at most 56 . Since the kernel is contained in $\bigoplus_{\alpha \in S} H^{0}\left(\omega_{B_{\alpha}}^{\otimes 3}\left(2 A_{\alpha}\right)\right)$, we see that the dimension of $H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 3}\right)$ is at most $112+56+56=224$ which is the rank of $H^{0}\left(V, \omega_{V}^{\otimes 3}\right)$. Hence $i_{3}$ is an isomorphism.
q.e.d.

Remark 3.2. This proof implies that the homomorphisms (6), (7) and (8) are surjective. This is also true for the homomophism $i_{m}^{\prime}$.

Proposition 3.3. Let $H$ be a subgroup of $G$, and let $\omega$ be an element of $H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes m}\right)$ for $m=2$ or 3. If $\omega$ is $H$-invariant, then there exists an element $\tilde{\omega} \in H^{0}\left(V, \omega_{V}^{\otimes m}\right)$ which is $H$-invariant and $\left.\tilde{\omega}\right|_{V_{0}}=\omega$.

Proof. Let $S_{0}$ be a 2-Sylow subgroup of $H$. Then since $S_{0}$ is contained in a 2-Sylow subgroup of $G, S_{0}$ acts on $V$ freely by a result of Mumford. Let $V^{\prime}$ be the quotient $V / S_{0}$. Since $\omega$ is $S_{0}$-invariant, it descends to an element of $H^{0}\left(V_{0}^{\prime}, \omega_{V_{0}^{( }}^{\otimes m}\right)$. By Proposition 3.1, there exists
$\tilde{\omega}^{\prime} \in H^{0}\left(V^{\prime}, \omega_{V^{\prime}}\right)$ with $\left.\tilde{\omega}^{\prime}\right|_{V_{0}^{\prime}}=\omega$. We regard $\tilde{\omega}^{\prime}$ as an $S_{0}$-invariant element of $H^{0}\left(V, \omega_{V}^{\otimes 2}\right)$. Let $H=S_{0} \alpha_{1}+\cdots+S_{0} \alpha_{n}$ be the left coset decomposition of $H$ with respect to $S_{0}$. Let $\tilde{\omega}=\sum_{i=1}^{n} \alpha_{i}^{*}\left(\tilde{\omega}^{\prime}\right)$. Then $\tilde{\omega}$ is $H$-invariant, and $\left.\tilde{\omega}\right|_{V_{0}}=n \omega=\omega$, since $n=\left[H: S_{0}\right]$ is an odd number. q.e.d.

TheOrem 3.4. Let $H$ be a subgroup of $G$ and let $m$ be 2 or 3. Then the homomorphism

$$
H^{0}\left(V, \omega_{V}^{\otimes m}\right)^{H} \underset{Z_{2}}{\otimes} \boldsymbol{F}_{2} \rightarrow H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes m}\right)^{H}
$$

induced by $i_{m}$ is an isomorphism.
Proof. Since the quotient $H^{0}\left(V, \omega_{V}^{\otimes m}\right) / H^{0}\left(V, \omega_{V}^{\otimes m}\right)^{H}$ is contained in the $\boldsymbol{Q}_{2}$-module $H^{0}\left(V_{\eta}, \omega_{V_{\eta}}^{\otimes m}\right) / H^{0}\left(V_{\eta}, \omega_{V_{\eta}}^{\otimes m}\right)^{H}$, it is a free $\boldsymbol{Z}_{2}$-module. Hence $H^{0}\left(V, \omega_{V}^{\otimes m}\right)^{H}$ is a direct summand of $H^{0}\left(V, \omega_{V}^{\otimes m}\right)$. In particular, the homomorphism is injective. Since $m=2$ or 3 , it is surjective by Proposition 3.3.
q.e.d.

The following shows that the bigenus $P_{2}$ of the desingularization of the quotient surface $V_{\eta} / H$ is calculated only in terms of the closed fiber $V_{0}$.

Proposition 3.5. Let $H$ be a subgroup of $G$, and let $\widetilde{Z}$ be the minimal resolution of $Z=V_{\eta} / H$. Then $P_{2}(\widetilde{Z})=\operatorname{dim} H^{0}\left(V_{0}, \omega_{v_{0}}^{\left.\otimes_{2}^{2}\right)^{H}}\right.$.

Proof. By Theorem 3.4, we have $\operatorname{dim} H^{0}\left(V_{\eta}, \omega_{V_{\eta}}^{\otimes 2}\right)^{H}=\operatorname{dim} H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 2}\right)^{H}$. By Theorem 2.9, $Z$ may only have at most cyclic quotient singularities of types $(3,2)$ or ( 7,3 ), and the morphism $V_{\eta} \rightarrow Z$ is ramified only at these singular points. Hence an element $s \in H^{\circ}\left(V_{\eta}, \omega_{V_{\eta}}^{\otimes^{2}}\right)^{H}$ can be regarded as a section of $\omega_{Z^{\prime}}^{\otimes 2}$, where $Z^{\prime}=Z \backslash\{$ singular points\}. Note that $\widetilde{Z}$ contains $Z^{\prime}$ as an open subset. It suffices to show that the rational section $s$ of $\omega_{\widetilde{Z}}^{\otimes_{2}}$ has no pole along the exceptional divisors. This is the case over the cyclic quotient singularities of type ( 3,2 ), since they are rational double points. Let $y \in Z$ be a cyclic quotient singularity of type (7, 3) and let $D_{1}, D_{2}, D_{3}$ be the exceptional curves for the resolution of $y$ with $D_{1}{ }^{2}=$ $-3, D_{2}{ }^{2}=D_{3}{ }^{2}=-2, D_{1} \cdot D_{2}=D_{2} \cdot D_{3}=1$ and $D_{1} \cdot D_{3}=0$.

We can write the divisor (s) on $\widetilde{Z}$ as $a D_{1}+b D_{2}+c D_{3}+F$, where the support of $F$ contains none of $D_{i}$ 's. Let $d_{i}$ be the intersection number $D_{i} \cdot F$ for $i=1,2,3$. Since (s) is linearly equivalent to $2 K_{\tilde{z}}$, we have

$$
\begin{aligned}
& 2=(s) \cdot D_{1}=-3 a+b+d_{1}, \\
& 0=(s) \cdot D_{2}=a-2 b+c+d_{2}, \\
& 0=(s) \cdot D_{3}=b-2 c+d_{3} .
\end{aligned}
$$

By these equalities, we calculate easily that

$$
\begin{aligned}
& 7 a=3\left(d_{1}-2\right)+2 d_{2}+d_{3} \\
& 7 b=2\left(d_{1}-2\right)+6 d_{2}+3 d_{3}, \\
& 7 c=\left(d_{1}-2\right)+3 d_{2}+5 d_{3} .
\end{aligned}
$$

Since $a, b, c$ are integers and $d_{1}, d_{2}, d_{3}$ are nonnegative, we have $a, b, c \geqq 0$. Hence $s$ has no pole on $\tilde{Z}$.
q.e.d.

Recall that $\Gamma_{2}=\langle\sigma, \tau\rangle$ stabilizes the component $B$ of $\mathscr{X}_{0}$. We denote by $G_{21}$ the injective image of $\Gamma_{2}$ in $G . \quad G_{21}$ is a group of order 21. Since $G_{21} \cap S=\{1\}$, $G$ is equal to the disjoint union $\cup_{\alpha \in S} G_{21} \alpha$. If an element $\beta$ is in $G_{21} \alpha$, then $\beta$ induces an isomorphism $\left(\left.\beta\right|_{B_{1}}\right): B_{1} \rightarrow B_{\alpha}$.

The action of $G$ on $V_{0}$ induces an action on the diagram (1). An element $\left(\omega_{\alpha}\right)_{\alpha \in S} \in \bigoplus_{\alpha \in S} H^{0}\left(B_{\alpha}, \omega_{B_{\alpha}}^{\otimes m}\left(m A_{\alpha}\right)\right)$ is $G$-invariant if and only if $\left(\left.\beta\right|_{B_{1}}\right)^{*} \omega_{\alpha}=\omega_{1}$ for every $\beta \in G$, where $\alpha$ is the element of $S$ with $\beta \in G_{21} \alpha$. This is also equivalent to the condition that $\omega_{1}$ is $G_{21}$-invariant and $\omega_{1}=\left(\left.\alpha\right|_{B_{1}}\right)^{*} \omega_{\alpha}$ for every $\alpha \in S$.

Suppose ( $\omega_{\alpha}$ ) is $G$-invariant. By the diagram (1), ( $\omega_{\alpha}$ ) is in $H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes m}\right)^{G}$ if and only if $\varepsilon^{*}\left(\left(\omega_{\alpha}\right)\right)=\gamma^{*}\left(\left(\omega_{\alpha}\right)\right)$. Since the action of $G$ on the set of double curves of $V_{0}$ is transitive, this equality holds if they coincide on a component of $\widetilde{D}$. Recall that, for $\alpha=\tau \rho \sigma \tau, C(1,0,0) \subset B$ and $\alpha^{\wedge}(E(1,0,0)) \subset \alpha^{\wedge}(B)$ form a double curve of $\mathscr{X}_{0}$. The isomorphism $\kappa$ of the identification $E(1,0,0) \rightarrow C(1,0,0)$ is given by $\left(X_{1}: X_{2}\right) \mapsto\left(X_{2}: X_{1}\right)$.

We set

$$
L_{m}=\left\{\omega \in H^{0}\left(B, \omega_{B}^{\otimes m}(m A)\right)^{\Gamma_{2}} ; \kappa^{*}\left(\left.\omega\right|_{C(1,0,0)}\right)=\left.\omega\right|_{E(1,0,0)}\right\} .
$$

By the expression (4) for $H^{0}\left(B, \omega_{B}^{\otimes m}(m A)\right)$, we see easily that $L_{m}$ is naturally isomorphic to $L_{m}^{\prime} \subset \boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ consisting of $\Gamma_{2}$-invariant homogeneous polynomials $f$ of degree $4 m$ such that $f\left(1, X_{1}, X_{2}\right)$ has no terms of degree smaller than $m$ and $f\left(0, X_{2}, X_{1}\right) / X_{1}^{m} X_{2}^{m}\left(X_{1}+X_{2}\right)^{m}=\left[f\left(1, X_{1}, X_{2}\right)\right]_{m}$. where $[g]_{m}$ denotes the homogeneous part of degree $m$ of a polynomial $g$. Note that $f$ has zero of multiplicity at least $m$ at ( $1,0,0$ ) if and only if $f\left(1, X_{1}, X_{2}\right)$ has no terms of degree smaller than $m$. By the above observation, we have the following:

Proposition 3.6. $H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes m}\right)^{G}$ is isomorphic to $L_{m}$ by the correspondence $\left(\omega_{\alpha}\right)_{\alpha \in S} \mapsto \omega_{1}^{\prime}$ where $\omega_{1}^{\prime}$ is the pull-back of $\omega_{1}$ by the natural isomorphism $B \xrightarrow[\rightarrow]{\sim} B_{1}$. Hence it is also isomorphic to $L_{m}^{\prime}$.

For any $\alpha \in G L\left(3, F_{2}\right)$, we have $\alpha^{*}\left(f / u_{0}^{m}(d y / y \wedge d z / z)^{\otimes m}\right)=\left(\alpha^{*} f\right) / u_{0}^{m}(d y / y$ $\wedge d z / z)^{\otimes m}$ for $f / u_{0}^{m}(d y / y \wedge d z / z)^{\otimes m} \in H^{0}\left(B, \omega_{B}^{\otimes m}(m A)\right)$, where $f$ is a homogeneous polynomial of degree 4 m . Hence, in order to determine the $\Gamma_{2}$ invariant elements of $H^{0}\left(\omega_{B}^{\otimes m}(m A)\right)$, we have to know those of $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$.

Recall that $\lambda=(-1+\sqrt{-7}) / 2$ is embedded in $Z_{2}$ so that $\lambda \equiv 0(\bmod 2)$. Hence, for $\zeta=\exp (2 \pi i / 7), \boldsymbol{Q}_{2}(\zeta)$ is a cubic extension of $\boldsymbol{Q}_{2}$ with the relation $\zeta^{3}-\lambda \zeta^{2}-(1+\lambda) \zeta-1=0$. We denote by $\zeta_{0}$ the modulo 2 reduction of $\zeta$, i.e., $\zeta_{0}$ is a root of the equation $X^{3}+X+1=0$ in $F_{2}[X]$.

The following method to find $\Gamma_{2}$-invariant polynomials in $F_{2}\left[X_{0}, X_{1}, X_{2}\right]$ is due to Nakamura.

We set

$$
\begin{aligned}
& Y_{0}=X_{0}+\zeta_{0}{ }^{2} X_{1}+\zeta_{0} X_{2}, \\
& Y_{1}=X_{0}+\zeta_{0}{ }^{4} X_{1}+\zeta_{0}{ }^{2} X_{2} \\
& Y_{2}=X_{0}+\zeta_{0} X_{1}+\zeta_{0}{ }^{4} X_{2}
\end{aligned}
$$

Note that this is the modulo 2 reduction of the coordinate change in Remark 2.10, since

$$
\left[\begin{array}{lll}
1 & 1 & 1 \\
\zeta_{0}{ }^{2} & \zeta_{0}{ }^{4} & \zeta_{0} \\
\zeta_{0} & \zeta_{0}{ }^{2} & \zeta_{0}{ }^{4}
\end{array}\right]=\left[\begin{array}{lll}
1 & \zeta_{0} & \zeta_{0}{ }^{2} \\
1 & \zeta_{0}{ }^{2} & \zeta_{0}{ }^{4} \\
1 & \zeta_{0}{ }^{4} & \zeta_{0}
\end{array}\right]^{-1}
$$

Then we have

$$
\begin{array}{ll}
\tau\left(Y_{0}\right)=\zeta_{0} Y_{0}, \quad \tau\left(Y_{1}\right)=\zeta_{0}{ }^{2} Y_{1}, \quad \tau\left(Y_{2}\right)=\zeta_{0}^{4} Y_{2} \\
\sigma\left(Y_{0}\right)=Y_{2}, \quad \sigma\left(Y_{1}\right)=Y_{0} \quad \text { and } \quad \sigma\left(Y_{2}\right)=Y_{1}
\end{array}
$$

Thus, if a polynomial $f$ in $\overline{\boldsymbol{F}}_{2}\left[Y_{0}, Y_{1}, Y_{2}\right]$ is $\tau$-invariant, then it is a sum of $\tau$-invariant monomials in $Y_{0}, Y_{1}$ and $Y_{2}$.

A monomial $Y_{0}{ }^{i} Y_{1}{ }^{j} Y_{2}{ }^{k}$ is $\tau$-invariant if and only if $i+2 j+4 k \equiv 0$ $(\bmod 7)$. If it is $\tau$-invariant, then

$$
F_{i, j, k}=Y_{0}^{i} Y_{1}^{j} Y_{2}^{k}+Y_{0}^{k} Y_{1}^{i} Y_{2}^{j}+Y_{0}^{j} Y_{1}^{k} Y_{2}^{i}
$$

is $\Gamma_{2}$-invariant. Conversely, every $\Gamma_{2}$-invariant polynomial in $\overline{\boldsymbol{F}}_{2}\left[Y_{0}, Y_{1}, Y_{2}\right]$ is a linear combination of $F_{i, j, k}$ 's.

Proposition 3.7. For any $i, j, k$ with $i+2 j+4 k \equiv 0(\bmod 7), F_{i, j, k}$ is in $F_{2}\left[X_{0}, X_{1}, X_{2}\right]$. Conversely, every $\Gamma_{2}$-invariant polynomial in $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ is a sum of $F_{i, j, k}$ 's.

Proof. Clearly, $F_{i, j, k} \in F_{2}\left(\zeta_{0}\right)\left[X_{0}, X_{1}, X_{2}\right]$. Let $u$ be the automorphism of $F_{2}\left(\zeta_{0}\right)\left[X_{0}, X_{1}, X_{2}\right]$ defined by $u\left(X_{i}\right)=X_{i}$ for $i=0,1,2$ and $u\left(\zeta_{0}\right)=\zeta_{0}{ }^{2}$. Then, a polynomial $f$ in $\boldsymbol{F}_{2}\left(\zeta_{0}\right)\left[X_{0}, X_{1}, X_{2}\right]$ is in $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ if and only
if $u(f)=f$. Since $u\left(Y_{0}\right)=Y_{1}, u\left(Y_{1}\right)=Y_{2}, u\left(Y_{2}\right)=Y_{0}$, we have $u\left(F_{i, j, k}\right)=$ $F_{i, j, k}$.

Suppose $F \in \boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$ is $\Gamma_{2}$-invariant. Since $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right] \subset$ $\boldsymbol{F}_{2}\left(\zeta_{0}\right)\left[Y_{0}, Y_{1}, Y_{2}\right], F$ is written uniquely as a linear combination of $F_{i, j, k}$ 's with coefficients in $\boldsymbol{F}_{2}\left(\zeta_{0}\right) \backslash\{0\}$. Since $u\left(F_{i, j, k}\right)=F_{i, j, k}$, the coefficients are in $\boldsymbol{F}_{2} \backslash\{0\}=\{1\}$.
q.e.d.

We denote by $\operatorname{Inv}_{n}$ the $\boldsymbol{F}_{2}$-vector space of $\Gamma_{2}$-invariant homogeneous polynomials of degree $n$ in $\boldsymbol{F}_{2}\left[X_{0}, X_{1}, X_{2}\right]$. By the above proposition, we can easily find bases for $\operatorname{Inv}_{n}$ for small $n$ 's as follows:

$$
\begin{aligned}
& \operatorname{Inv}_{0}=(1) . \\
& \operatorname{Inv}_{1}=\operatorname{Inv}_{2}=\{0\} . \\
& \operatorname{Inv}_{3}=\left(\phi_{3}\right), \quad \phi_{3}=Y_{0} Y_{1} Y_{2} . \\
& \operatorname{Inv}_{4}=\left(\phi_{4}\right), \quad \phi_{4}=Y_{0} Y_{1}^{3}+Y_{1} Y_{2}^{3}+Y_{2} Y_{0}^{3} . \\
& \operatorname{Inv}_{5}=\left(\phi_{5}\right), \quad \phi_{5}=Y_{0}^{3} Y_{1}^{2}+Y_{1}^{3} Y_{2}^{2}+Y_{2}^{3} Y_{0}^{2} . \\
& \operatorname{Inv}_{6}=\left(\phi_{3}^{2}, \phi_{8}\right), \phi_{6}=Y_{0}^{5} Y_{1}+Y_{1}^{5} Y_{2}+Y_{2}^{5} Y_{0} . \\
& \operatorname{Inv}_{7}=\left(\phi_{3} \phi_{4}, \phi_{7}\right), \phi_{7}=Y_{0}^{7}+Y_{1}^{7}+Y_{2}^{7} . \\
& \operatorname{Inv}_{8}=\left(\phi_{4}^{2}, \phi_{3} \phi_{5}\right) .
\end{aligned}
$$

We can also show that $\operatorname{Inv}_{12}$ is generated by $\left\{F_{10,2,0}, F_{3,9,0}, F_{5,6,1}, F_{7,8,2}\right.$, $\left.F_{4,4,4}\right\}$. Hence

$$
\operatorname{Inv}_{12}=\left(\phi_{3}{ }^{4}, \phi_{3}{ }^{2} \phi_{6}, \phi_{3} \phi_{4} \phi_{5}, \phi_{5} \phi_{7}, \phi_{6}{ }^{2}\right),
$$

Table 1

| $f$ | $f\left(0, X_{2}, X_{1}\right)$ | $f\left(1, X_{1}, X_{2}\right) \bmod \left(X_{1}, X_{2}\right)^{4}$ |
| :---: | :--- | :--- |

since $F_{10,2,0}=\phi_{6}{ }^{2}, F_{3,9,0}=\phi_{5} \phi_{7}+\phi_{8}{ }^{2}+\phi_{3}{ }^{2} \phi_{6}, F_{5,6,1}=\phi_{3} \phi_{4} \phi_{5}+\phi_{3}{ }^{4}+\phi_{8}^{2}{ }^{2} \phi_{8}, F_{7,3,2}=$ $\phi_{3}{ }^{2} \phi_{6}$ and $F_{4,4,4}=\dot{\phi}_{3}{ }^{4}$.

In order to determine $L_{m}^{\prime}$ for $m=2$, 3 , we provide the Tables 1 and 2 of $f\left(0, X_{2}, X_{1}\right)$ and $f\left(1, X_{1}, X_{2}\right)$ for $f=\phi_{i}$ and each element of the basis for $\operatorname{Inv}_{12}$. In the tables, we omit the part of degree greater than 3 of $f\left(1, X_{1}, X_{2}\right)$.

Proposition 3.8. We have $L_{2}^{\prime}=\left(\phi_{4}{ }^{2}+\phi_{3} \phi_{5}\right)$ and $L_{3}^{\prime}=\left(\phi_{5} \phi_{7}+\phi_{3}{ }^{4}, \phi_{3} \phi_{4} \phi_{5}+\phi_{6}{ }^{2}\right)$. In particular, $\operatorname{dim} H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 2}\right)^{G}=1$ and $\operatorname{dim} H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 3}\right)^{G}=2$.

Proof. The second assertion follows from the first by Proposition 3.6. In $\operatorname{Inv}_{8} \backslash\{0\}$, only $\phi_{4}{ }^{2}+\phi_{3} \phi_{5}$ has zero of multiplicity 2 at ( $1,0,0$ ). For $f=\phi_{4}{ }^{2}+\phi_{3} \phi_{5}$, we calculate easily by Table 1 that $\left[f\left(1, X_{1}, X_{2}\right)\right]_{2}=$ $f\left(0, X_{2}, X_{1}\right) / X_{1}^{2} X_{2}^{2}\left(X_{1}+X_{2}\right)^{2}=X_{1}^{2}+X_{1} X_{2}+X_{2}^{2}$. Hence $L_{2}^{\prime}$ is generated by $\phi_{4}{ }^{2}+\phi_{3} \phi_{5}$.

From Table 2, the $\boldsymbol{F}_{2}$-vector space $\left\{f \in \operatorname{Inv}_{12} ; f\right.$ has zero of multiplicity 3 at $(1,0,0)\}$ is of dimension 3 and is generated by $\left\{\phi_{8}{ }^{2}+\phi_{3}{ }^{4}, \phi_{5} \phi_{7}+\right.$ $\left.\phi_{3}{ }^{4}, \phi_{3} \phi_{4} \phi_{5}+\phi_{3}{ }^{4}\right\}$. Hence it is easy to see that $L_{3}^{\prime}=\left(\phi_{5} \phi_{7}+\phi_{3}{ }^{4}, \phi_{3} \phi_{4} \phi_{5}+\phi_{8}{ }^{2}\right)$. Actually, we have

$$
f\left(0, X_{2}, X_{1}\right) / X_{1}^{3} X_{2}^{3}\left(X_{1}+X_{2}\right)^{3}=\left[f\left(1, X_{1}, X_{2}\right)\right]_{3}=X_{1}^{3}+X_{1} X_{2}^{2}+X_{2}^{3}
$$

for $f=\phi_{5} \phi_{7}+\phi_{3}{ }^{4}$, and

$$
f\left(0, X_{2}, X_{1}\right) / X_{1}^{3} X_{2}^{3}\left(X_{1}+X_{2}\right)^{3}=\left[f\left(1, X_{1}, X_{2}\right)\right]_{3}=X_{1}^{3}+X_{1}^{2} X_{2}+X_{2}^{3}
$$

for $f=\phi_{3} \phi_{4} \phi_{5}+\phi_{6}{ }^{2}$.
We now prove the following:
Theorem 3.9. For the minimal resolution $Y_{\eta}^{\prime}$ of $Y_{\eta}=V_{\eta} / G$, we have $P_{2}\left(Y_{\eta}^{\prime}\right)=P_{3}\left(Y_{\eta}^{\prime}\right)=1$. We can choose as generators of $H^{0}\left(Y_{\eta}^{\prime}, \omega_{Y_{n}^{(22}}^{\otimes 2}\right)$ and $H^{0}\left(Y_{\eta}^{\prime}, \omega_{Y_{\eta}}^{\otimes_{j}^{3}}\right)$, the elements which corresponds to the $\Gamma_{2}$-invariant polynomilals $\phi_{4}{ }^{2}+\phi_{3} \phi_{5}$ and $\phi_{3}{ }^{4}+\phi_{3} \phi_{4} \phi_{5}+\phi_{5} \phi_{7}+\phi_{8}{ }^{2}$ by the modulo 2 reduction, respectively.

Proof. We have $P_{2}\left(Y_{\eta}^{\prime}\right)=1$ by Propositions 3.5, 3.6 and 3.8. By Proposition 3.8, $H^{0}\left(Y_{\eta}^{\prime}, \omega_{Y_{n}}^{\otimes_{n}^{2}}\right)$ is generated by the lifting of the element of $H^{0}\left(V_{0}, \omega_{V_{0}}^{\otimes 2}\right)^{G}$ which corresponds to $\phi_{4}{ }^{2}+\phi_{3} \phi_{5}$.

By Theorem 2.9 and Remark 2.10, $Y$ has cyclic quotient singularity of type ( 7,3 ) along $\bar{q}$, and it is minimally resolved simultaneously in $Y^{\prime}$.

Let $s$ be a section of $\omega_{Y^{\prime \prime}}^{\otimes 3}$, where $Y^{\prime \prime}$ is the smooth part $Y \backslash\{\bar{p}, \bar{q}, w\}$ of $Y$. For the resolution of $Y_{\eta}$ at $q$, we define the exceptional divisors $D_{1}, D_{2}, D_{3}$ in $Y_{\eta}^{\prime}$ and integers $a, b, c$ and $d_{1}, d_{2}, d_{3} \geqq 0$ similarly as in the proof of Proposition 3.5. Then we have

$$
7 a=3\left(d_{1}-3\right)+2 d_{2}+d_{3}
$$

$$
\begin{aligned}
& 7 b=2\left(d_{1}-3\right)+6 d_{2}+3 d_{3} \\
& 7 c=\left(d_{1}-3\right)+3 d_{2}+5 d_{3}
\end{aligned}
$$

Hence $b, c \geqq 0$ and $a \geqq-1$. In other words, $s$ is regular at the divisors $D_{2}, D_{3}$ and may have a pole of order at most one along $D_{1}$.

Let $L_{i}$ be the intersection of the closure of $D_{i}$ with $Y_{0}^{\prime}$ for $i=1,2,3$. Then $L=L_{1} \cup L_{2} \cup L_{3}$ is the exceptional curve of $\bar{q}(0) \in Y_{0}$. Let $U \subset Y_{0}^{\prime}$ be a smooth neighborhood of $L$ and let $\omega_{0}$ be a rational section of $\omega_{U}^{\otimes 3}$ which is regular outside $L$. Then, as in the case of the generic fiber, $\omega_{0}$ may have a pole of order at most one along $L_{1}$ When $\omega_{0}$ is represented by an element of $H^{0}\left(B, \omega_{B}^{\otimes_{B}^{3}}(3 A)\right)^{\Gamma_{2}}$, its regularity at $L_{1}$ is examined as follows:

Let $f\left(Y_{0}, Y_{1}, Y_{2}\right)$ be the corresponding $\Gamma_{2}$-invariant homogeneous polynomial of degree 12 in $Y_{i}$ 's. We take the local coordinate $\left(y_{1}, y_{2}\right)=$ $\left(Y_{1} / Y_{0}, Y_{2} / Y_{0}\right)$ of the point $\left(1: \zeta_{0}: \zeta_{0}{ }^{2}\right) \in \boldsymbol{P}^{2} \overline{\boldsymbol{F}}_{2}=\operatorname{Proj} \overline{\boldsymbol{F}}_{2}\left[X_{0}, X_{1}, X_{2}\right]$. Then the action of $\tau$ is given by $\left(y_{1}, y_{2}\right) \mapsto\left(\zeta_{0} y_{1}, \zeta_{0}{ }^{3} y_{2}\right)$ (cf. Remark 2.10). In the resolution, $L$ is covered by four affine open sets with coordinates ( $y_{1}{ }^{7}, y_{1}^{-3} y_{2}$ ), $\left(y_{1}^{3} y_{2}^{-1}, y_{1}^{-2} y_{2}^{3}\right),\left(y_{1}^{2} y_{2}^{-3}, y_{1}^{-1} y_{2}^{5}\right)$ and $\left(y_{1} y_{2}^{-5}, y_{2}^{7}\right)$, where the second and the third coordinates are of the neighborhoods of $L_{1} \cap L_{2}$ and $L_{2} \cap L_{3}$, respectively. The divisor $L_{1}$ is described as the line ( $s=0$ ) with respect to the coordinate $(s, t)=\left(y_{1}^{7}, y_{1}^{-3} y_{2}\right) . \quad \omega_{0}$ is equal to $v \cdot f\left(1, y_{1}, y_{2}\right)\left(d y_{1} \wedge d y_{2}\right)^{\otimes 3}$ for a non-vanishing regular function $v$ on $U$. In view of the equality $d y_{1} \wedge d y_{2}=$ $(1 / 7) s^{-3 / 7} d s \wedge d t$, we see that $\omega_{0}$ has a pole at $L_{1}$ if and only if $s^{-9 / 7} g(s, t)$ has a pole along ( $s=0$ ), where $g(s, t)=f\left(1, y_{1}, y_{2}\right)$.

Among $\tau$-invariant monomials of degree 12 in $Y_{i}$ 's only $s^{-9 / 7} g(s, t)$ for $Y_{0}{ }^{10} Y_{1}{ }^{2}$ has a pole along $(s=0)$. Hence $\omega_{0}$ 's which correspond to $\phi_{5} \phi_{7}+\phi_{3}{ }^{4}=$ $F_{10,2,0}+F_{3,8,0}+F_{7,3,2}+F_{4,4,4}$ and $\phi_{3} \phi_{4} \phi_{5}+\phi_{6}{ }^{2}=F_{10,2,0}+F_{5,6,1}+F_{7,3,2}+F_{4,4,4}$ have a pole along $L_{1}$, while $\omega_{0}$ for $\dot{\phi}_{3}{ }^{4}+\dot{\phi}_{3} \phi_{4} \phi_{5}+\phi_{5} \phi_{7}+\phi_{6}{ }^{2}=F_{3,8,0}+F_{5,6,1}$ does not.

Let $\omega_{\eta}$ be an element of $H^{0}\left(Y_{\eta}^{\prime \prime}, \omega_{Y{ }^{\prime}}^{\otimes 3}\right)$ which has nontrivial reduction $\omega_{0}$ to $Y_{0}^{\prime \prime}$. Then $\omega_{\eta}$ has a pole at $D_{1}$, if so does $\omega_{0}$ at $L_{1}$. Hence, by Theorem 3.4, there exists $\omega \in H^{0}\left(Y_{\eta}^{\prime \prime}, \omega_{Y_{\eta^{\prime}}}^{\otimes 3}\right)$ with a pole along $D_{1}$. Since $D_{1}$ is a nonsingular rational curve and $D_{1}{ }^{2}=-3$, we have $\left.\omega_{Y^{\prime}}^{\otimes_{3}^{3}}\left(D_{1}\right)\right|_{D_{1}} \simeq \mathcal{O}_{D_{1}}$. Hence $H^{0}\left(Y_{\eta}^{\prime}, \omega_{Y \eta}^{\otimes 33}\right)$ is of codimension one in $H^{0}\left(Y_{\eta}^{\prime}, \omega_{Y_{\eta}}^{\otimes 3}\left(D_{1}\right)\right)$, which is isomorphic to $H^{0}\left(Y_{\eta}^{\prime \prime}, \omega_{Y_{n}^{\prime \prime}}^{\otimes 3}\right)$, since the other singularities $p_{0}, p_{1}, p_{2}$ are rational double points. Since $H^{0}\left(Y_{\eta}^{\prime \prime}, \omega_{Y \eta_{\eta}^{\prime}}^{\otimes 3}\right) \simeq H^{0}\left(V_{\eta}, \omega_{V_{\eta}}^{\otimes 3}{ }^{G}\right.$ is of dimension two by Theorem 3.4 and Proposition 3.8, we have $\operatorname{dim} H^{0}\left(Y_{\eta}^{\prime}, \omega_{Y_{\eta}}^{\otimes 3}\right)=1$. q.e.d.

Remark 3.10. The $\Gamma_{2}$-invariant polynomials $f_{2}=\phi_{4}{ }^{2}+\phi_{3} \phi_{5}$ and $f_{3}=$ $\phi_{3}{ }^{4}+\phi_{3} \phi_{4} \phi_{5}+\phi_{5} \phi_{7}+\dot{\phi}_{8}{ }^{2}$ are equal to $F_{2,6,0}+F_{4,3,1}$ and $F_{3,9,0}+F_{5,6,1}$, respectively. By expressing these polynomials in terms of the coordinates at $L_{1} \cap L_{2}$ and $L_{2} \cap L_{3}$ in the proof of the above theorem, we see that gene-
rators of $H^{0}\left(Y_{\eta}^{\prime}, \omega_{Y \eta}^{\otimes m}\right)$ for $m=2,3$ and their modulo 2 reductions have no zero along $D_{i}^{\prime}$ 's and $L_{i}$ 's, respectively.
4. The minimal resolution of $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$. In this section, we denote by $X$ the normal surface $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$. By Theorem 2.9, $X$ has cyclic quotient singularities $p_{0}, p_{1}, p_{2}$ and $q$. Let $\pi: \widetilde{X} \rightarrow X$ be the minimal resolution of these singularities. Hence $\widetilde{X}=Y^{\prime}\left(\bar{Q}_{2}\right)$ for $Y^{\prime}$ in Remark 2.10. We denote by $D_{1}, \cdots, D_{9}$ the irreducible divisors of $\tilde{X}$ such that $\pi^{-1}(q)=D_{1}+D_{2}+D_{3}$, $\pi^{-1}\left(p_{0}\right)=D_{4}+D_{5}, \quad \pi^{-1}\left(p_{1}\right)=D_{6}+D_{7}$ and $\pi^{-1}\left(p_{2}\right)=D_{8}+D_{9}$. We assume $D_{1}{ }^{2}=-3$ and $D_{1} \cap D_{3}=\varnothing$ as in Section 3. Hence we have $D_{i}{ }^{2}=-2$ for $2 \leqq i \leqq 9$. Let $K_{X}$ be a canonical divisor of $X$. Since $X$ has only cyclic quotient singularities, $K_{X}$ is a $Q$-Cartier divisor. In fact, $21 K_{X}$ is a Cartier divisor.

Proposition 4.1. The Chern numbers of the nonsingular surface $\tilde{X}$ are $c_{1}{ }^{2}(\tilde{X})=0$ and $c_{2}(\tilde{X})=12$.

Proof. Let $K_{\tilde{X}}$ be the canonical divisor of $\tilde{X}$ which is equal to $K_{X}$ on $X \backslash\left\{p_{0}, p_{1}, p_{2}, q\right\}$. Then $\pi^{*} K_{X}-K_{\tilde{X}}$ is a $\boldsymbol{Q}$-divisor supported in $D_{1} \cup \cdots \cup D_{9}$, i.e., $\pi^{*} K_{X}-K_{\tilde{X}}=a_{1} D_{1}+\cdots+a_{9} D_{\theta}$ for some $a_{1}, \cdots, a_{\theta} \in \boldsymbol{Q}$. Since $D_{i}^{\prime}$ 's are nonsingular rational curves, we have $\left(\pi^{*} K_{X}-K_{\tilde{x}}\right) \cdot D_{i}=$ $-K_{\tilde{X}} \cdot D_{i}=2+D_{i}{ }^{2}$ for every $i$.

Then we see easily that

$$
\pi^{*} K_{X}-K_{\tilde{x}}=(3 / 7) D_{1}+(2 / 7) D_{2}+(1 / 7) D_{3}
$$

In particular, we have

$$
\begin{equation*}
K_{X}^{2}-K_{\widetilde{X}}{ }^{2}=\left(\pi^{*} K_{X}-K_{\tilde{X}}\right) \cdot K_{\tilde{X}}=3 / 7 \tag{1}
\end{equation*}
$$

On the other hand, by Theorem 2.9, there exists a finite morphism $f: V\left(\overline{\boldsymbol{Q}}_{2}\right) \rightarrow X$ of degree 168 ramified only at $\left\{p_{0}, p_{1}, p_{2}, q\right\}$. Since $c_{1}^{2}\left(V\left(\overline{\boldsymbol{Q}}_{2}\right)\right)=$ 72, we have

$$
\begin{equation*}
K_{X}^{2}=72 / 168=3 / 7 \tag{2}
\end{equation*}
$$

Hence $c_{1}^{2}(\widetilde{X})=K_{\tilde{X}}{ }^{2}=0$ by (1) and (2).
For $c_{2}(\widetilde{X})$, we may let $\overline{\boldsymbol{Q}}_{2}=\boldsymbol{C}$ and calculate it as the topological Euler number $e(\widetilde{X})$. By Theorem 2.9, $f^{-1}\left(p_{i}\right)$ for $i=0,1,2$ and $f^{-1}(q)$ consist of $168 / 3=56$ and $168 / 7=24$ points, respectively. Since $c_{2}\left(V\left(\bar{Q}_{2}\right)\right)=24$, we have

$$
\begin{align*}
c_{2}(\tilde{X}) & =\left(c_{2}\left(V\left(\overline{\boldsymbol{Q}}_{2}\right)\right)-{ }^{\ddagger} f^{-1}\left(\left\{p_{0}, p_{1}, p_{3}, q\right\}\right)\right) / 168+e\left(\pi^{-1}\left(\left\{p_{0}, p_{1}, p_{2}, q\right\}\right)\right) \\
& =(24-(3 \cdot 56+24)) / 168+(3 \cdot 3+4)=12 .
\end{align*}
$$

Remark 4.2. The above proposition implies $\chi\left(\mathcal{O}_{\tilde{x}}\right)=1$ by Noether's
formula. In fact, we have $p_{g}(\widetilde{X})=q(\widetilde{X})=0$, since $X$ has a finite covering $M\left(\overline{\boldsymbol{Q}}_{2}\right) \rightarrow X$ from Mumford's fake projective plane $M\left(\overline{\boldsymbol{Q}}_{2}\right)$ ramified only at finite points.

Proposition 4.3. $\widetilde{X}$ is a minimal elliptic surface, i.e., the Kodaira dimension of $\tilde{X}$ is equal to one.

Proof. Suppose $\tilde{X}$ were of general type, and let $X^{\prime}$ be its minimal model. By the plurigenus formula, we have $P_{m}(\widetilde{X})=(m(m-1) / 2) K_{X^{\prime}}{ }^{2}+$ $\chi\left(\mathcal{O}_{\tilde{X}}\right)$ for $m \geqq 2$. In particular $P_{2}(\widetilde{X}) \geqq 2$. This contradicts Theorem 3.9.

If $\tilde{X}$ were of Kodaira dimension zero, then $\tilde{X}$ is either a $K 3$ surface or an Enriques surface, since $q(\widetilde{X})=0$. These are impossible since $p_{g}(\tilde{X})=0$ and $P_{3}(\tilde{X})=1$ by Theorem 3.9.

Hence $\tilde{X}$ is an elliptic surface and it is minimal by $K_{\tilde{X}}{ }^{2}=0$. q.e.d.
Recall that the $Z_{2}$-scheme $Y^{\prime}$ is regular outside the point $w$ in the closed fiber. For each integer $m$, we denote by $\omega_{Y}^{\otimes m}$ the maximal torsionfree extension of $\omega_{Y^{\prime}}^{\otimes^{m}} \backslash\{w\}$ to $Y^{\prime}$. We fix sections $F_{2}$ and $F_{3}$ of $\omega_{Y^{\prime}}^{\otimes 2}$ and $\omega_{Y^{\prime}}^{\otimes 3}$ with non-trivial modulo 2 reductions, respectively, which exist by Theorem 3.9. Let $E^{\prime}$ and $E^{\prime \prime}$ be the effective divisors ( $F_{2}$ ) and ( $F_{3}$ ) of $Y^{\prime}$, respectively. Clearly, $3 E^{\prime}$ and $2 E^{\prime \prime}$ are linearly equivalent.

Lemma 4.4. $E^{\prime}$ and $E^{\prime \prime}$ are disjoint.
Proof. Let $\pi_{0}: Y_{0}^{\prime} \rightarrow Y_{0}$ be the natural morphism. We denote by $\bar{E}_{0}^{\prime}$ and $\bar{E}_{0}^{\prime \prime}$ the images by $\pi_{0}$ of the divisors $E_{0}^{\prime}=E^{\prime} \cap Y_{0}^{\prime}$ and $E_{0}^{\prime \prime}=E^{\prime \prime} \cap Y_{0}^{\prime}$, respectively.

By the definition of $E^{\prime}$ and $E^{\prime \prime}$ and by Theorem $3.9, \bar{E}_{0}^{\prime}$ and $\bar{E}_{0}^{\prime \prime}$ correspond to the $\bar{\Gamma}_{2}$-invariant polynomials $f_{2}=\phi_{4}{ }^{2}+\phi_{3} \phi_{5}$ and $f_{3}=\phi_{3}{ }^{4}+\phi_{3} \phi_{4} \phi_{5}+\phi_{5} \phi_{7}+\phi_{6}{ }^{2}$, respectively. Let $\widetilde{E}_{0}^{\prime}$ and $\widetilde{E}_{0}^{\prime \prime}$ be the pull-backs of $\bar{E}_{0}^{\prime}$ and $\bar{E}_{0}^{\prime \prime}$, respectively, by the natural surjective morphism $h: B \rightarrow Y_{0}$. By Tables 1 and 2, the restrictions of $\widetilde{E}_{0}^{\prime \prime}$ and $\widetilde{E}_{0}^{\prime \prime}$ to the rational curve $C(1,0,0) \subset B$ is defined by $X_{1}{ }^{2}+X_{1} X_{2}+X_{2}{ }^{2}$ and $X_{1} X_{2}\left(X_{1}+X_{2}\right)$, respectively. In particular, they do not intersect each other on the curve. Since $G$ acts transitively on the set of double curves of $V_{0}$, and since $B$ is isomorphic to the component $B_{1}$ of $V_{0}, \widetilde{E}_{0}^{\prime}$ and $\widetilde{E}_{0}^{\prime \prime}$ do not intersect each other on the fourteen rational curves in Figure 1 in Section 1. Since the complement of the union of the curves in $B$ is an affine open set, $\widetilde{E}_{0}^{\prime}$ and $\widetilde{E}_{0}^{\prime \prime}$ have no common components. $E_{0}^{\prime}$ and $E_{0}^{\prime \prime}$ also have no common components, since they do not contain $L_{i}$ for $i=1,2,3$ by Remark 3.10 , and since $E_{0}^{\prime}$ does not have any zero on the other exceptional curves of $\pi_{0}$.

On the other hand, $f_{2}$ and $f_{3}$ have zeros of multiplicities 2 and 3 , re-
spectively, at the seven $\boldsymbol{F}_{2}$-rational points of $\boldsymbol{P}_{\boldsymbol{F}_{2}}^{2}$. Since $B$ is the blowingup of $\boldsymbol{P}_{\boldsymbol{F}_{2}}^{2}$ at the seven $\boldsymbol{F}_{2}$-rational points, the intersection number $\widetilde{E}_{0}^{\prime} \cdot \widetilde{E}_{0}^{\prime \prime}$ is $\operatorname{deg} f_{2} \cdot \operatorname{deg} f_{3}-7 \cdot 2 \cdot 3=96-42=54$. Since $Y_{0} \backslash h(C(1,0,0))$ is smooth except at the cyclic quotient singularity $\bar{q}(0)$, we can consider the intersection number $\bar{E}_{0}^{\prime} \cdot \bar{E}_{0}^{\prime \prime}=54 / 21=18 / 7$, since $h$ is of degree 21 . As in the proof of Proposition 4.1, we have

$$
\begin{aligned}
& \pi_{0}^{*} \bar{E}_{0}^{\prime}-E_{0}^{\prime}=2\left((3 / 7) L_{1}+(2 / 7) L_{2}+(1 / 7) L_{3}\right), \\
& \pi_{0}^{*} \bar{E}_{0}^{\prime \prime}-E_{0}^{\prime \prime}=3\left((3 / 7) L_{1}+(2 / 7) L_{2}+(1 / 7) L_{3}\right) \text { and } \\
& \bar{E}_{0}^{\prime} \cdot \bar{E}_{0}^{\prime \prime}-E_{0}^{\prime} \cdot E_{0}^{\prime \prime}=2 \cdot 3 \cdot 3 / 7=18 / 7
\end{aligned}
$$

Hence $E_{0}^{\prime} \cdot E_{0}^{\prime \prime}=0$. We have $E_{0}^{\prime} \cap E_{0}^{\prime \prime}=\varnothing$, since they have no common components. This implies $E^{\prime} \cap E^{\prime \prime}=\varnothing$.
q.e.d.

Let $\kappa: Y^{\prime} \rightarrow \boldsymbol{P}_{Z_{2}}^{1}$ be the morphism defined by $\left(F_{2}{ }^{3}, F_{3}{ }^{2}\right)$.
Proposition 4.5. The induced morphism $\kappa^{1} \overline{\mathbf{Q}}_{2}: \widetilde{X} \rightarrow \boldsymbol{P}^{1} \overline{\mathbf{Q}}_{2}$ of the geometric fibers is the elliptic fibration of $\tilde{X}$. It has just two multiple fibers $3 E^{\prime} \overline{\overline{\widehat{a}}}_{2}$ and $2 E^{\prime \prime} \overline{\bar{Q}}_{2}$, where $E^{\prime} \overline{\bar{Q}}_{2}$ and $E^{\prime \prime}{\overline{\bar{Q}_{2}}}$ are the restrictions of $E^{\prime}$ and $E^{\prime \prime}$ to $\widetilde{X}$, respectively.

Proof. Let $f: \widetilde{X} \rightarrow \boldsymbol{P}_{\overline{\mathbf{Q}}_{2}}$ be the elliptic fibration, and let $m_{1} C_{1}, \cdots, m_{n} C_{n}$ be its multiple fibers. By Kodaira's canonical bundle formula [Ko2, Th. 12], we have

$$
K_{\tilde{x}} \sim f^{-1}\left(-x_{0}\right)+\sum_{i=1}^{n}\left(m_{i}-1\right) C_{i},
$$

where $x_{0}$ is a point of $\boldsymbol{P}^{1}{ }_{\mathbf{Q}_{2}}$, since $\operatorname{deg} K_{P^{1}}+\chi\left(\mathcal{O}_{\tilde{x}}\right)=-1$. Since $2 K_{\tilde{X}} \sim$ $(n-2) f^{-1}\left(x_{0}\right)+\sum_{i=1}^{n}\left(m_{i}-2\right) C_{i}$, we have $\operatorname{dim}\left|2 K_{\tilde{x}}\right|=n-2$. Hence $n=2$ by Theorem 3.9. Since $E^{\prime} \overline{\mathbf{Q}}_{2}$ is a unique effective bicanonical divisor, we have $E^{\prime \prime} \bar{Q}_{2}=\left(m_{1}-2\right) C_{1}+\left(m_{2}-2\right) C_{2}$. If $m_{1}, m_{2} \geqq 3,3 K_{\tilde{X}} \sim f^{-1}\left(x_{0}\right)+\left(m_{1}-3\right) C_{1}+$ $\left(m_{2}-3\right) C_{2}$ and hence $\operatorname{dim}\left|3 K_{\tilde{X}}\right|=1$. This contradicts Theorem 3.9. Hence we may assume $m_{1}=2$. Since $\left(m_{2}-2\right) C_{2}=E^{\prime} \overline{\bar{Q}}_{2}$, we have $m_{2}>2$. Hence $3 K_{\tilde{X}} \sim E^{\prime \prime} \overline{\bar{Q}}_{2}=C_{1}+\left(m_{2}-3\right) C_{2}$. Since $E^{\prime} \overline{\mathbf{Q}}_{2} \cap E^{\prime \prime} \overline{\bar{Q}}_{2}=\varnothing$ by Lemma 4.4, we have $m_{2}=3$.

Thus we have $E^{\prime \prime} \overline{\overline{\mathbf{Q}}}_{2}=C_{2}, E^{\prime \prime} \overline{\overline{\mathbf{Q}}}_{2}=C_{1}$ and $f^{-1}\left(x_{0}\right) \sim 3 E^{\prime} \overline{\overline{\mathbf{Q}}}_{2} \sim 2 E^{\prime \prime} \overline{\overline{\mathbf{Q}}}_{2}$. Hence $f$ is equal to $\kappa_{\overline{\mathbf{Q}}_{2}}$ up to automorphism of $\boldsymbol{P}^{1} \overline{\mathbf{Q}}_{2}$. ${ }^{\text {. }}$

The connected curves $D_{2} \cup D_{3}, D_{4} \cup D_{5}, D_{6} \cup D_{7}$ and $D_{8} \cup D_{9}$ are unions of (-2)-curves. Hence they are mapped to points in $\boldsymbol{P}^{1} \overline{\mathbf{Q}}_{2}$ by $\boldsymbol{\kappa}_{\overline{\mathbf{Q}}_{2}}$. We denote $y=\kappa_{\bar{Q}_{2}}\left(D_{2} \cup D_{3}\right)$ and $z_{i}=\kappa_{\overline{\mathbf{Q}}_{2}}\left(D_{4+2 i} \cup D_{5+2 i}\right)$ for $i=0,1,2$.

Proposition 4.6. $\quad E^{\prime \prime} \overline{\mathbf{Q}}_{2}, E^{\prime \prime}{\overline{\bar{Q}_{2}}}_{2}, D_{2} \cup D_{3}, D_{4} \cup D_{5}, D_{8} \cup D_{7}$ and $D_{8} \cup D_{9}$ are mapped to distinct points in $\boldsymbol{P}_{\overline{\mathbf{Q}}_{2}}$ by $\boldsymbol{\kappa}_{\overline{\boldsymbol{Q}}_{2}}$.

Proof. By definition, $\kappa_{\overline{\mathbf{Q}}_{2}}\left(E^{\prime} \overline{\mathbf{Q}}_{2}\right)=(0: 1)$ and $\kappa_{\overline{\mathbf{Q}}_{2}}\left(E^{\prime \prime}{\overline{\mathbf{Q}_{2}}}^{2}\right)=(1: 0)$. By Remark 3.10, the modulo 2 reduction $L_{2} \cup L_{3}$ of $D_{2} \cup D_{3}$ is contained in neither $E_{0}^{\prime}$ nor $E_{0}^{\prime \prime}$. Hence the specialization of $y$ in $\boldsymbol{P}_{F_{2}}^{1}$ is neither (1:0) nor ( $0: 1$ ). As we saw immediately before Theorem 2.9, there exists a $\boldsymbol{Z}_{2}$-morphism Spec $\boldsymbol{Z}_{2}[\varepsilon] \rightarrow \mathscr{X}$ which is fixed by $\tau \rho$, and the induced $\boldsymbol{Q}_{2}[\varepsilon]-$ valued point in $Y$ splits to $p_{0}, p_{1}, p_{2}$ in $Y\left(\overline{\boldsymbol{Q}}_{2}\right)$ and the image of the closed point is the triple point $P$ of $\mathscr{X}_{0}$. As we saw in the proof of Lemma 4.4, the pull-back of $\bar{E}^{\prime}$ and $\bar{E}^{\prime \prime}$ to $C(1,0,0)$ is defined by $X_{1}^{2}+X_{1} X_{2}+X_{2}^{2}$ and $X_{1} X_{2}\left(X_{1}+X_{2}\right)$, respectively. Hence we have $\bar{P} \in \bar{E}^{\prime \prime}$ and $\bar{P} \notin \bar{E}^{\prime}$, where $\bar{P}$ is the image of $P$ in $Y$. Since $D_{4} \cup D_{5}, D_{6} \cup D_{7}$ and $D_{8} \cup D_{9}$ are the exceptional curves of $p_{0}, p_{1}$ and $p_{2}$, respectively, the specialization of $z_{i}$ 's are all (1:0). We get the following diagram after the base extension in Remark 2.10:

Here $K$ is the quotient field of $R=\boldsymbol{Z}_{2}[\zeta, \omega], V_{R}^{\prime}$ a neighborhood of $P_{1} \in V_{R}$, $\bar{E}_{R}^{\prime}$ the image of $E_{R}^{\prime}$ in $Y_{R}$ and $\boldsymbol{A}_{R}^{1}=\boldsymbol{P}_{R}^{1} \backslash \kappa_{R}\left(E_{R}^{\prime}\right)$. It suffices to show that the $K$-homomorphism $\mu^{*}: K[t] \rightarrow K[\varepsilon]$ is surjective, since then the image of $\mu$ is a separable point of degree 3 while ( $1: 0$ ) is the $K$-rational point $t=0$. By the notation in Remark 2.10, we get the following sequence of formal completions of local rings:

$$
R \llbracket t \rrbracket \rightarrow R \llbracket T_{0}, T_{1}^{3}, T_{2}^{3}, T_{1} T_{2} \rrbracket \rightarrow R \llbracket T_{0}, T_{1}, T_{2} \rrbracket \xrightarrow{l} R[\varepsilon],
$$

where $T_{0}, T_{1}, T_{2}$ have a relation $T_{0}^{3}+T_{1}^{3}+T_{2}^{3}-3 T_{0} T_{1} T_{2}=27 \varepsilon^{3} . l$ is given by $l\left(T_{0}\right)=3 \varepsilon$ and $l\left(T_{1}\right)=l\left(T_{2}\right)=0$. The image of $t$ in $R \llbracket T_{0}, T_{1}, T_{2} \rrbracket$ is equal to $F_{3}{ }^{2} / F_{2}^{3}$. Since $Y$ is a Gorenstein scheme and since $F_{2}$ and $F_{3}$ are sections of $\omega_{Y}^{\otimes m}$ for $m=2,3$, respectively, we may regard $F_{2}$ and $F_{3}$ as elements of $R \llbracket T_{0}, T_{1}^{3}, T_{2}^{3}, T_{1} T_{2} \rrbracket$. By the restriction of the polynomials $f_{2}$ and $f_{3}$ to $C(1,0,0) \subset B$, we see that $F_{3} \in\left(T_{0}, T_{1}, T_{2}\right) \backslash\left(T_{0}, T_{1}, T_{2}\right)^{2}$ and $F_{2}$ is a unit. Hence $F_{3}$ has a unit coefficient for $T_{0}$, and hence $F_{3}{ }^{2} / F_{2}^{3}$ has a unit coefficient for $T_{0}{ }^{2}$. This implies that the image of $t$ in $R[\varepsilon]$ is outside $R$. Hence $\mu^{*}$ is surjective.
q.e.d.

Now we can determine the types of the singular fibers:
Theorem 4.7. The elliptic fibration $\kappa_{\overline{\boldsymbol{Q}}_{2}}: \widetilde{X} \rightarrow \boldsymbol{P}_{\overline{\boldsymbol{Q}}_{2}}$ has singular fibers at $\left\{(1: 0),(0: 1), y, z_{0}, z_{1}, z_{2}\right\} \subset P^{1} \overline{\mathbf{Q}}_{2}$ and smooth elsewhere. The singular
fibers over $z_{0}, z_{1}, z_{2}$ and $y$ are not multiple and are of type $I_{3}$ in the notation of [Ko1, Th. 6.2]. The fibers over (1:0) and (0:1) are $2 E^{\prime \prime} \overline{\mathbf{Q}}_{2}$ and $3 E^{\prime \prime} \overline{\mathbf{Q}}_{2}$, respectively, where $E^{\prime \prime} \overline{\mathbf{Q}}_{2}$ and $E^{\prime \prime} \overline{\mathbf{Q}}_{2}$ are smooth elliptic curves.

Proof. Each of the fibers over $z_{0}, z_{1}, z_{2}$ and $y$ contains a union of two (-2)-curves intersecting each other transversally at one point. Hence they are not of type II nor III. Hence the Euler number of the nonelliptic fiber is at least three and is equal to three if and only if it is of type $I_{3}$. Now we apply Kodaira's formula for the second Betti number of an elliptic surface [Ko1, Th. 12.2]. Since $c_{2}(\tilde{X})=12$ by Proposition 4.1, all these fibers are of type $I_{3}$ and the other fibers are elliptic curves. The multiple fibers are only $2 E^{\prime \prime} \overline{\mathbf{e}}_{2}$ and $3 E^{\prime} \overline{\mathbf{Q}}_{2}$ by Proposition 4.5. q.e.d.
