

## THE SUPPORT PROPERTY OF A CONVEX SET IN A LINEAR NORMED SPACE

BY V. L. KLEE, JR.

1. **Introduction.** In a linear normed space  $S$ , each translate of a linear proper subset of  $S$  is called a linear variety, and a maximal closed linear variety is called a *hyperplane*. That is, the linear variety  $H$  is a hyperplane if there is no closed linear variety  $L$  such that  $H \subset L \subset S$  and  $H \neq L \neq S$ . If  $H$  is a hyperplane and  $X$  a subset of  $S$ ,  $X$  is said to *lie on one side of  $H$*  if each line segment joining two points of  $X \sim H$  is disjoint from  $H$ . (We will reserve the minus sign “-” for linear differences, and the plus sign “+” for linear sums. Set differences and sums will be denoted respectively by “ $\sim$ ” and “ $\cup$ ”, set products by “ $\cap$ ”.) If  $X$  lies on one side of  $H$  and the distance between  $X$  and  $H$  is zero,  $H$  is said to be a *plane of support* of  $X$ . If in addition  $H$  contains the boundary point  $p$  of  $X$ ,  $X$  is said to be supported at  $p$  by  $H$ .

These definitions may be stated equivalently in terms of linear functionals on  $S$ . Thus each hyperplane can be characterized for some linear functional  $f \neq 0$  on  $S$  and some constant  $c$  as the set  $[f; c]$  of all points  $x$  in  $S$  for which  $f(x) = c$ .  $X$  lies on one side of  $[f; c]$  if  $f(x) \geq c$  for each  $x$  in  $X$  or  $f(x) \leq c$  for each  $x$  in  $X$ .  $X$  is supported at  $p$  by  $[f; c]$  if  $X$  lies on one side of  $[f; c]$  and  $f(p) = c$ .

It is well known that a convex set in Euclidean  $n$ -space is supported at each of its boundary points. (The simplest proofs of this fact are those by Botts and McShane in [2].) As we show by an example in §4 of this paper, this statement does not necessarily hold in an arbitrary linear normed space. (Another example is given in [4].) In fact, in each space  $l^p$  for  $p \geq 1$  there is a closed convex set which is supported only at each point of a set of first category in its boundary. We are able, however, to establish the results indicated below in Theorems 1-3.

**THEOREM 1.** *If  $C$  is a closed convex cone and  $C \neq S$ , then  $C$  has at least one plane of support.*

**THEOREM 2.** *If  $C$  is convex and has an interior point, then  $C$  is supported at each of its boundary points.*

**THEOREM 3.** *If  $C$  is closed and convex and satisfies any one of the following conditions,  $C$  is supported at each point of a set dense in its boundary.*

- (i) *Bounded sets in  $C$  are weakly compact;*
- (ii)  *$S$  is an adjoint space and bounded sets in  $C$  are weakly compact as sets of functionals;*
- (iii)  *$S$  is an adjoint space and  $C$  is transfinitely closed in  $S$ .*
