

## SETS SUBTENDING A CONSTANT ANGLE ON A CIRCLE

BY JOHN W. GREEN

1. **Introduction.** Let  $C$  be a closed circular area in the plane,  $C'$ , its boundary, and  $K$ , a closed convex set in  $C$  which subtends at every point of  $C'$  the same angle  $\alpha$ ,  $0 < \alpha < \pi$ . By this is meant that, at each point  $P$  of  $C'$  the angle between the two extreme supporting half lines to  $K$  at  $P$  is equal to  $\alpha$ . If  $K$  is a circular area concentric with  $C$  and of radius  $\sin \frac{1}{2}\alpha$  times the radius of  $C$ , it does subtend the angle  $\alpha$  on  $C'$ . The question arises then as to whether or not the fact that  $K$  subtends a constant angle on  $C'$  implies that  $K$  is such a circle. (This problem was suggested by Professor F. A. Valentine at a seminar given by the author.)

It is shown in the following that the answer depends on the nature of the angle  $\alpha$ . Let  $\beta = \pi - \alpha$ ; we shall call  $K$  a  $\beta$ -set if  $K$  subtends  $\pi - \beta$  on  $C'$ . If  $\beta$  is an irrational multiple of  $\pi$ , or if  $\beta = (m/n)\pi$  where  $m/n$  in its lowest terms has even numerator, the only  $\beta$ -set is the concentric circle of radius  $\cos \frac{1}{2}\beta$ . If  $\beta$  is any other angle between zero and  $\pi$ , there exist non-circular  $\beta$ -sets, and these can be constructed with a considerable degree of arbitrariness.

In the case where non-circular  $\beta$ -sets are possible, a number of extremal properties are found, involving their perimeters, diameters, and widths.

For facts and formulas relating to convex bodies, used but not proved, see [1].

2. **A necessary and sufficient condition for a  $\beta$ -set.** Let  $C$  be of radius 1 and centered at the origin of the  $x$ - $y$  plane. Let  $p(\theta)$  be the supporting function of  $K$ , that is, the distance from the origin to the supporting line normal to that half line issuing from the origin and making an angle  $\theta$  with the  $x$  axis. It is easily verified in our case that  $K$  must contain the origin as an interior point and that  $K$  can have no points on  $C'$ , and so  $0 < p(\theta) < 1$ . Let  $P$  be on  $C'$  and  $S_1, S_2$  be the two supporting lines to  $K$  through  $P$ , which intersect in the angle  $\pi - \beta$ . If half lines  $R_1$  and  $R_2$  are drawn from  $O$ , normal to  $S_1$  and  $S_2$ , respectively, one will make an angle  $\theta$  with the  $x$  axis and the other, an angle  $\theta + \beta$ . The distances from the origin to the supporting lines are  $p(\theta)$  and  $p(\theta + \beta)$ , and one is led to the relation

$$(1) \quad \cos^{-1} p(\theta) + \cos^{-1} p(\theta + \beta) = \beta.$$

Here and henceforth the arc cosine will denote first quadrant angles. If in (1),  $\theta$  is advanced by  $\beta$ , the result will, when subtracted from (1), yield  $p(\theta) = p(\theta + 2\beta)$ ; that is,  $2\beta$  is a period of  $p(\theta)$ . Now  $2\pi$  is also a period of  $p(\theta)$ ; hence, if  $\beta$  is an irrational multiple of  $\pi$ ,  $p(\theta)$  will have two incommensurable periods and, being continuous, will be constant. This makes  $K$  a circle with  $O$  as center.
