#### CONNECTIVITY FUNCTIONS WITH A PERFECT ROAD

Let  $X$  and  $Y$  be topological spaces. A function  $f:X \rightarrow Y$  is said to be a connectivity function provided that if  $A$  is a connected subset of  $X$ , then the graph of  $f$  restricted to  $A$  is a connected subset of  $X \times Y$ . A function  $f:X \rightarrow Y$  is said to be an almost continuous function provided that if  $O$  is an open subset of  $X \times Y$  containing the graph of  $f$ , then there exists a continuous function  $g:X \rightarrow Y$  such that  $O$  contains the graph of  $g$ . A real-valued function  $f$  defined on an interval is said to have a perfect road at the point  $x$  provided that there exists a perfect set  $P$  such that  $x$  is a bilateral point of accumulation of  $P$  and such that  $f$  restricted to  $P$  is continuous at  $x$ .

Let  $I$  be the closed unit interval. In order that a function  $f:I \rightarrow I$  be a connectivity function, it is necessary and sufficient that the graph of the entire function be connected. However, if  $f:I^2 \rightarrow I$  and the entire graph is connected it is not guaranteed that  $f$  is a connectivity function. Also, if  $f:I \rightarrow I$  is an almost continuous function, then  $f$  is a connectivity function. But there exist connectivity functions  $f:I \rightarrow I$  that are not almost continuous, [3], [7], [10]. However, if  $f:I^2 \rightarrow I$  is a connectivity function, then  $f$  is an almost continuous function, [11], but the converse is not true. Using these facts a negative answer was given to the
