

## ASYMPTOTIC LINES ON RULED SURFACES HAVING TWO RECTILINEAR DIRECTRICES.

BY DR. VIRGIL SNYDER.

(Read, in part, before the American Mathematical Society, at the Fifth Summer Meeting, August 19, 1898, and at the Annual Meeting, December 29, 1898.)

LET  $l$  be a generator of a non-developable ruled surface  $S$ , and let  $\pi_s$  be the tangent plane to  $S$  at a point  $P$  on  $l$ . As  $P$  moves along  $l$ ,  $\pi_s$  will turn about  $l$  in such a way that the range ( $P$ ) and the axial pencil ( $\pi_s$ ) are homographic (Chasles's correlation).

Again, let  $l$  be a line of a linear complex  $C$ , and let  $\pi_c$  be the polar plane in  $C$  of a point  $P$  on  $l$ . As  $P$  moves along  $l$ ,  $\pi_c$  will turn about  $l$  in such a way that the range ( $P$ ) and the axial pencil ( $\pi_c$ ) are homographic (normal correlation).

The two axial pencils ( $\pi_s$ ) and ( $\pi_c$ ), being homographic with a common range ( $P$ ), are projective with each other when  $l$  belongs to  $S$  and to  $C$ . These two projective pencils have two self-corresponding planes,  $\pi_1$  and  $\pi_2$ , such that the point of tangency and pole coincide; let the corresponding points be  $P_1$  and  $P_2$ .

If all the generators  $l$  of  $S$  belong to  $C$ , there will be two points on each, such that the tangent plane and the polar plane coincide. The locus of these points will be a curve traced on the surface, called the *complex curve*.

Let  $P'$  be a point on the curve contiguous to  $P$ , then  $PP'$  is a line of  $C$ , hence all the tangents to the curve belong to the complex  $C$ . The complex curve is an asymptotic line on the surface, because all its osculating planes are also tangent planes, a characteristic property of the asymptotic lines. This theorem may be stated as follows: *Every ruled surface contained in a linear complex has an asymptotic line, all of whose tangents belong to the complex.*

When the surface is algebraic, the order of this asymptotic line can be easily determined.\* Consider any plane  $\alpha$  and let it cut the curve in a point  $K$ ; the polar plane of  $K$  with regard to  $C$ , which is also the tangent plane to the surface at  $K$ , will pass through  $A$ , the pole of the plane  $\alpha$ . But every line of this polar plane  $\alpha$  of  $K$  is a tangent to the sur-
