## NEW POINT CONFIGURATIONS AND ALGEBRAIC CURVES CONNECTED WITH THEM*

## ARNOLD EMCH

1. Introduction. In the memorial volume $\dagger$ for Professor Hayashi, I studied an involutorial Cremona transformation in a projective $S_{r}$ which is obtained as follows: Let $C_{i}=(a x)_{i} \lambda_{i}{ }^{2}+(b x)_{i} \lambda_{i}+(c x)_{i}=0$, ( $i=1,2, \cdots, r$ ), be $r$ hypercones in $S_{r}$. Every value of $\lambda_{i}$ determines a hypertangent plane to the cone $C_{i}$. Thus the parameters $\lambda_{1}, \lambda_{2}, \cdots, \lambda_{r}$ for the hypercones $C_{1}, C_{2}, \cdots, C_{r}$, in the same order, determine $r$ hyperplanes which intersect in a point ( $x$ ) of $S_{r}$. From this point ( $x$ ) there pass, one for each of the $r$ hypercones, $r$ more tangent hyperplanes whose parameters $\lambda_{1}^{\prime}, \lambda_{2}^{\prime}, \cdots, \lambda_{r}^{\prime}$ are in the same order uniquely determined by the set $\lambda_{1}, \lambda_{2}, \cdots, \lambda_{r}$, and hence are rational functions

$$
\rho \lambda_{i}^{\prime}=\phi_{i}\left(\lambda_{1}, \lambda_{2}, \cdots, \lambda_{r}\right), \quad i=1,2, \cdots, r
$$

of the parameters $\lambda$. Conversely, the set $\lambda_{1}^{\prime}, \lambda_{2}^{\prime}, \cdots, \lambda_{r}^{\prime}$ determines $\lambda_{i}$ uniquely: $\sigma \lambda_{i}=\phi_{i}\left(\lambda_{1}^{\prime}, \lambda_{2}^{\prime}, \cdots, \lambda_{r}^{\prime}\right)$. If therefore the $\lambda^{\prime}$ 's and $\lambda^{\prime \prime}$ 's are interpreted as coordinates of points of euclidean spaces $E_{r}(\lambda)$ and $E_{r}^{\prime}\left(\lambda^{\prime}\right)$, there exists an involutorial Cremona transformation between the two $r$-dimensional spaces. The order and fundamental elements of this involution were determined in the corresponding projective spaces $S_{r}$ and $S_{r}^{\prime}$ and applications given for $S_{2}$ and $S_{3}$. These belong to a remarkable class of involutions which have the property that when in $S_{r}$ and $S_{r}^{\prime}$

$$
P\left(\lambda_{1}, \lambda_{2}, \lambda_{3}, \cdots, \lambda_{r+1}\right), \quad P^{\prime}\left(\lambda_{1}^{\prime}, \lambda_{2}^{\prime}, \lambda_{3}^{\prime}, \cdots, \lambda_{r+1}^{\prime}\right)
$$

are corresponding points and any number of transpositions between coordinates in the same columns is performed, say

$$
\begin{aligned}
& Q\left(\lambda_{1}, \lambda_{2}^{\prime}, \lambda_{3}^{\prime}, \cdots, \lambda_{\imath}^{\prime}, \cdots, \lambda_{r}, \cdots, \lambda_{r+1}^{\prime}\right), \\
& Q^{\prime}\left(\lambda_{1}^{\prime}, \lambda_{2}, \lambda_{3}, \cdots, \lambda_{i}, \cdots, \lambda_{r}^{\prime}, \cdots, \lambda_{r+1}\right),
\end{aligned}
$$

then $Q, Q^{\prime}$ is always a couple of corresponding points of the involution.

To this class also belong the well known quadratic and cubic involutions in $S_{2}, \rho x_{i}^{\prime}=1 / x_{i},(i=1,2,3)$, and in $S_{3}, \rho x_{i}^{\prime}=1 / x_{i},(i=1,2,3,4)$,
