# SOME THEOREMS ON FACTORIZATION OF MEROMORPHIC FUNCTIONS 

BY FRED GROSS<br>Communicated by M. Gerstenhaber, March 13, 1968

In [3] the author proved
Theorem 1. ${ }^{1}$ If $f$ is any entire function of lower order less than $\frac{1}{2}$ and $g$ is entire, then $f(g)$ is periodic if and only if $g$ is.

By means of a result due to Edrei [1] and Ostrovskii [6] it is possible to generalize Theorem 1 to a certain class of meromorphic functions. We begin with

Lemma 1 (Edrei [1], Ostrovskii [6]). Let $f(z)$ be meromorphic of lower order $\lambda<\frac{1}{2}$. If $\delta(\infty, f)>1-\cos \pi \lambda$, then $\left|f\left(\mathrm{re}^{i \theta}\right)\right| \rightarrow \infty$, uniformly in $\theta$ as $r_{n} \rightarrow \infty$ through a suitable sequence.
Here $\delta$ is the Nevanlinna deficiency (see Hayman [5, p. 42]).
Theorem 2. Let $f$ be meromorphic of lower order $\lambda$ and let $g$ be entire. If $0 \leqq \lambda<\frac{1}{2}$ and for some $a, \delta(a, f)>1-\cos \pi \lambda$, then $f(g)$ is periodic if and only if $g$ is. If $\tau$ is a period of $f(g)$, then $g$ has a period having the same argument as $\tau$.

Sketch of Proof. We assume that $f(g)$ is periodic with period $\tau$ having argument $\alpha$. Let $L$ be the half line re ${ }^{i \alpha}$ everywhere except near poles of $f(g)$, where we let $L$ loop around them with radius $\epsilon, \epsilon$ a small positive number. Letting $f^{*}(z)=1 /(f(z)-a)$ and applying Lemma 1 we see that $\left|f^{*}\left(\mathrm{re}^{i \theta}\right)\right| \rightarrow \infty$, uniformly in $\theta$ as $r_{n} \rightarrow \infty$ through a suitable sequence. From the hypotheses of the theorem it follows that $f(g)$ is bounded on $L$. If $g$ is bounded on $L$, then as in the proof of Theorem 1 (see [3]) $g$ must be periodic with a period having the same argument as $\tau$. If $g$ is unbounded on $L$, then $f$ is bounded on $g(L)$ and this leads to a contradiction via Lemma 1.

Corollary. If $P$ is a polynomial and $f$ is as in Theorem 2, then $f(P)$ is not periodic.

This Corollary is a partial solution to the more general question suggested in [4]: If $f$ is meromorphic for which polynomials is $f(P)$ periodic?

[^0]
[^0]:    ${ }^{1} \mathrm{~N}$. Baker proved an analogue of this theorem for $f$ of order $<1 / 2$. See On some results of A. Renyi and C. Renyi concerning periodic entire functions, Acta Sci. Math. (Szeged) 27 (1966), 197-200.
