On Foran's Property (M) and its relation to
Lusin's Property (N)

In [1], J.Foran has constructed a continuous function F on $[0,1]$ satisfying on $[0,1]$ the Foran property (M), but which does not satisfy Lusin's property (N). In Theorem 3 we shall show that such a function may be obtained by using a result due by S.Mazurkiewicz more than fifty years ago [2]. Our strategy will be the following. We shall construct a continuous function F having on $[0,1]$ Lusin's property (N) such that for any linear nonconstant function g , the function $F+g$ has the Foran property (M), but does not have Lusin's property (N). Our idea is inspired by the S.Mazurkiewicz result [2] asserting the existence of a continuous function F having on $[0,1]$ Lusin's property (N) such that $F+g$ has the property (N) for no linear nonconstant function g .

As will become apparent, S.Mazurkiewicz' paper [2] anticipates implicitly the Foran property (M).

In Theorem 2 of our paper we indicate a new, shorter way to obtain the above-mentioned Mazurkiewicz Theorem.

Definition. A continuous function F is said to satisfy property (M) providing F is AC on any set E on which it is VB ([1]).

Remark 1. Lusin's condition (N) implies property (M), but the converse is not true. This was shown by Foran in [1]. In the present paper we give an example which is another proof of Foran's result.

Theorem 1. If F is a continuous function satisfying ACG on $[a,b]$, and if G is a continuous function satisfying (M) on $[a,b]$, then every linear combination of F and G , also satisfies (M) on $[a,b]$.

Proof. Let $H(x) = F(x) + G(x)$, $x \in [a,b]$. Suppose that $H(x)$ is VB on a set $E \subset [a,b]$ (E may be supposed closed). Since F is ACG on $[a,b]$, there is a sequence of sets E_n such that $E = \bigcup E_n$ and F is AC on E_n . Now it is clear that $G(x)$ is VB on each E_n . Since G satisfies (M) on $[a,b]$, it follows that G is ACG on E . Hence H is ACG on E . By the Banach-Zarecki Theorem ([3], pp.227), H is AC on E .

We shall now give a new, simplified proof of the above-mentioned S.Mazurkiewicz Theorem.

Theorem 2. (S.Mazurkiewicz). There exists a continuous function F having Lusin's property (N) on $[0,1]$ such that $F+g$ has property (N) for no linear nonconstant function g .

Proof. We shall first construct a function F and we shall show that it has the properties required

by Theorem 2. Let $n_1 \geq 2$ and let

$$n_k = 2^{k-1}(4n_1+5)\dots(4n_{k-1}+5) \quad , \quad k \geq 2$$

$$m_k = 2(n_k+1)(2n_k+1) + n_k \quad , \quad k \geq 1$$

$$a_k = 2/((2n_1+1)\dots(2n_k+1)) \quad , \quad k \geq 1$$

$$b_k = 2/((2n_1+1)\dots(2n_k+1)) \quad , \quad k \geq 1 .$$

Let $P = \{x : x = \sum a_i p_i \quad , \quad p_i = 0, \dots, m_i\}$ and

$$Q = \{y : y = \sum b_i q_i \quad , \quad q_i = 0, \dots, n_i\} .$$

Clearly $|P| = |Q| = 0$. We denote by $r(x;y)$ the remainder of the quotient x/y . Let F be a function

defined on $[0,1]$ as follows. For each $x \in P$,

$F(x) = F(\sum a_i p_i(x)) = \sum b_i r(p_i(x); n_i+1)$. Then F is continuous on P and, by extending F linearly on each

interval contiguous to P , one has F defined and continuous on $[0,1]$. Clearly $F(P) = Q$. Hence $|F(P)| =$

$= |Q| = 0$ and F fulfils (N). For any real $t \neq 0$

let $G_t(x) = F(x) + tx$, $x \in [0,1]$. Let

$$I_{i_1, \dots, i_k} = [c_{i_1, \dots, i_k}, d_{i_1, \dots, i_k}] \quad , \quad \text{where}$$

$$c_{i_1, \dots, i_k} = \sum_{p=1}^k i_p a_p \quad \text{and} \quad d_{i_1, \dots, i_k} = c_{i_1, \dots, i_k} +$$

$$+ \sum_{p \geq n+1} m_p a_p \quad , \quad i_j = 0, \dots, m_j \quad ; \quad j = 1, \dots, k .$$

Let $t > 0$. Then there is a natural number k such

that $t \in [1/2^k, 2^k]$. Since $2^k(2n_k+1) < b_k/a_k <$

$< (1/2^k)(m_k - n_k - 1)$, we have

$$G_t(I_{i_1, \dots, i_{k-1}, (n_k+1)j+i}) \cap$$

$$\cap G_t(I_{i_1}, \dots, i_{k-1}, (n_k+1)(j+1)+i) \neq \emptyset, \quad i=0, \dots, n_k,$$

$$j = 0, \dots, 4n_k+1 \quad \text{and}$$

$$G_t(c_{i_1}, \dots, i_{k-1}, i+1) < G_t(c_{i_1}, \dots, i_{k-1}, m_k - n_k + i),$$

$$i = 0, \dots, n_k-1. \quad \text{Now } G_t(I_{i_1}, \dots, i_{k-1} \cap P) =$$

$$= G_t(I_{i_1}, \dots, i_{k-1}). \quad \text{Since } |G_t(I_{i_1}, \dots, i_{k-1})| > 0,$$

G_t does not satisfy (N).

Let $t < 0$. Then there is a natural number k , such

that $-t \in [1/2^k, 2^k]$. Since $2^k(2n_k+3) < b_k/a_k <$

$< (1/2^k)(m_k - n_k + 1)$, we have

$$G_t(I_{i_1}, \dots, i_{k-1}, (n_k+1)j+i) \cap$$

$$\cap G_t(I_{i_1}, \dots, i_{k-1}, (n_k+1)(j+1)+i) \neq \emptyset,$$

$$i = 0, \dots, n_k, \quad j = 0, \dots, 4n_k+1, \quad \text{and}$$

$$G_t(c_{i_1}, \dots, i_{k-1}, i) > G_t(c_{i_1}, \dots, i_{k-1}, m_k - n_k + i + 1),$$

$$i = 0, \dots, n_k-1. \quad \text{Now } G_t(I_{i_1}, \dots, i_{k-1} \cap P) =$$

$$= G_t(I_{i_1}, \dots, i_{k-1}). \quad \text{Hence } G_t \text{ does not satisfy (N).}$$

The aim of the next theorem is to get another proof for the existence of a function considered in the Foran example.

Theorem 3. The function G_t considered in the proof of Theorem 2 has the Foran property (M), but does not have Lusin's property (N).

Proof. Since condition (N) implies the Foran property (M), by Theorem 1, it follows that G_t fulfils (M). Clearly, by Theorem 2, G_t does not satisfy condition (N) .

Remark 2. As can be seen from the proofs of Theorems 2 and 3, we get an uncountable class of functions of the type envisaged by Foran.

We are indebted to Professor Solomon Marcus for the help given in preparing this article and to the anonymous reviewer, for many remarks allowing to improve the final version of the text.
