# CONFORMALLY FLAT HYPERSURFACES <br> IN A EUCLIDEAN SPACE 

Seiki Nishikawa

(Received September 18, 1973)

Introduction. Let ( $M, g$ ), or simply $M$, be a Riemannian $n$-manifold with Riemannian metric $g$. Throughout this paper manifolds under consideration are always assumed to be connected and smooth unless otherwise stated. $M$ is called conformally flat if each point of $M$ has a neighborhood where there exists a conformal diffeomorphism onto an open subset in a Euclidean space. It is well-known that every Riemannian 2-manifold is conformally flat because of the existence of isothermal coordinates.

In this paper, we shall study conformally flat $n$-manifolds, $n>3$, which are also isometrically immersed in a Euclidean ( $n+1$ )-space as complete hypersurfaces, and determine the global form of such hypersurfaces under the following additional assumption:
(*) The Riemannian structure of ( $M, g$ ) and the isometric immersion under consideration are both analytic.

In fact, we prove the following theorem, which is the main result of this paper.

Theorem. Let $(M, g)$ be an analytic complete conformally flat Riemannian n-manifold, $n>3$, and $f: M \rightarrow E^{n+1}$ an analytic isometric immersion of $M$ into a Euclidean $(n+1)$-space $E^{n+1}$. Then $f(M)$ is one of the following forms:
(i) a flat hypersurface (i.e., a Euclidean n-space $E^{n}$, or a cylinder $E^{n-1} \times \gamma$ built over an analytic plane curve $\gamma$ ).
(ii) a tube (see §1, for definition; e.g., a Riemannian product manifold $S^{n-1} \times E^{1}$ ).
(iii) a surface of revolution (e.g., a Euclidean $n$-sphere $S^{n}$ ).

It should be remarked that the corresponding local result is true without completeness of $M$ and without analyticity condition (*) [1, 4, 5]. Roughly speaking, a general conformally flat hypersurface is obtained by smoothly glueing together pieces of hypersurfaces of the above three types, although arbitrary glueing is clearly not possible. Our additional assumption (*) makes it quite impossible to glue these pieces together.

Finally, we remark that a similar theorem has been announced by

Kulkarni [3] in the case where $M$ is compact.

1. Preliminaries. In this section we recall some known results on conformally flat hypersurfaces in a Euclidean space. For details see [4].

Let $f: M \rightarrow E^{n+1}$ be an isometric immersion of a (not necessarily complete) Riemannian $n$-manifold, $n>3$, into a Euclidean $(n+1)$-space $E^{n+1}$. In the following, when the argument is local in nature, we may consider $f$ as an imbedding and thus identify a point $x \in M$ with $f(x) \in E^{n+1}$.

Then the following has been known.
Lemma $1[1,4,5]$. Let $A$ be the second fundamental form of $M$, which is considered as a symmetric linear transformation on each tangent space of $M$. Then $M$ is conformally flat if and only if at each point of $M$, $A$ is one of the following types:
(I) $A=\lambda I, I=$ the identity transformation.
(II) $A$ has two distinct eigenvalues $\lambda$ and $\mu$ of multiplicity $n-1$ and 1 respectively.

The proof of this lemma is done by a straightforward calculation.
A point of $M$ is called an umbilical point if the second fundamental form $A$ takes the form (I) at the point. Otherwise we call the point a non-umbilical point.

For further studying, we choose a local field of orthonormal frames $e_{A}$ in $E^{n+1}$ such that, restricted to $M$, the vectors $e_{i}$ and $e_{n}$ are tangent to $M$ (and consequently, $e_{n+1}$ is normal to $M$ ), where and throughout the rest of this paper, we agree on the following ranges of indices:

$$
\begin{aligned}
& 1 \leqq A, B, C, \cdots \leqq n+1 \\
& 1 \leqq i, j, k, \cdots \leqq n-1
\end{aligned}
$$

With respect to the frame field chosen above, let $\omega_{A}$ and $\omega_{A B}$ be the field of dual frames and connection forms respectively. We restrict these forms to $M$. Then we have

$$
\omega_{n+1}=0
$$

Now we assume that $M$ is conformally flat. Then, on a (sufficiently small) neighborhood of a non-umbilical point, we can choose the above frame field $e_{A}$ in such a way that

$$
\begin{aligned}
& \omega_{i, n+1}=\lambda \omega_{i}, \\
& \omega_{n, n+1}=\mu \omega_{n},
\end{aligned}
$$

due to Lemma 1 together with the continuity of the second fundamental
form. Here $\lambda$ as well as $\mu$ is a smooth function on the neighborhood. For later convenience, we call such a frame field an adapted frame field around a non-umbilical point.

Then we have
Lemma 2 [4]. With respect to each adapted frame field around a non-umbilical point, the following hold:
(i) $\omega_{i n}=[1 /(\lambda-\mu)]\left(\lambda_{n} \omega_{i}+\mu_{i} \omega_{n}\right)$,
(ii) $\lambda_{j}=0$ and $\lambda_{n} \mu_{j}=0$ for $\cdot$ all $j$,
where we have put

$$
\begin{aligned}
& d \lambda=\sum \lambda_{i} \omega_{i}+\lambda_{n} \omega_{n} \\
& d \mu=\sum \mu_{i} \omega_{i}+\mu_{n} \omega_{n}
\end{aligned}
$$

For the proof of Lemma 2, see the literature.
Before going into the proof of the main theorem, we shall explain some examples of conformally flat hypersurfaces in a Euclidean space.

First, let $\gamma$ be an arbitrary smooth curve in $E^{n+1}$. Then the total space of the normal sphere bundle of $\gamma$ with (sufficiently small) fixed radius is, by definition, a tube. As is easily seen by Lemma 1, a tube is a conformally flat hypersurface in $E^{n+1}$.

Another example is a surface of revolution. Let $S$ be the envelope of a one-parameter family of hyperspheres in $E^{n+1}$. $S$ is called a surface of revolution if on a straight line there lies the locus of centers of hyperspheres of the family. From Lemma 1 , we see that $S$ is a conformally flat hypersurface in $E^{n+1}$. Note that a Euclidean $n$-sphere $S^{n}$ is a special type of such hypersurfaces.
2. Proof of the main theorem. Let $f: M \rightarrow E^{n+1}$ be an analytic isometric immersion of an analytic complete conformally flat Riemannian $n$-manifold $(M, g), n>3$, into a Euclidean $(n+1)$-space $E^{n+1}$. In the following, we always assume that $M$ is simply connected. This assumption does cause no loss of generality of our argument. In fact, take the universal Riemannian covering manifold $\pi: M^{*} \rightarrow M$ of $M$. Then $M^{*}$ is also an analytic complete conformally flat Riemannian manifold, and $f^{*}=f \circ \pi$ is an analytic isometric immersion of $M^{*}$ into $E^{n+1}$. Moreover, we have $f(M)=f^{*}\left(M^{*}\right)$.

For later use, we put

$$
\mathscr{U}=\{x \in M \mid x \text { is an umbilical point }\}
$$

and

$$
\mathscr{N}=\{x \in M \mid x \text { is a non-umbilical point }\}
$$

Then $\mathscr{U}$ is closed in $M$, and $\mathscr{N}$ is open in $M$, owing to the continuity of the second fundamental form.

First we divide the proof into the following two cases.
$C A S E$ I. $\mathscr{U}$ has an interior point.
Then the second fundamental form $A$ of $M$ takes the form

$$
\begin{equation*}
A=\lambda I, \lambda \text { is a real number } \tag{1}
\end{equation*}
$$

on a non-empty open subset of $M$. Note that $M$ admits an analytic field $e_{n+1}$ of unit normal vectors defined on $M$ due to the simple connectedness of $M$. Thus both sides of the equation (1) are analytic tensor fields defined globally on $M$. Hence we have $A=\dot{\lambda} I$ on $M$.

Consequently $f(M)$ is either a Euclidean $n$-space $E^{n}$ or a Euclidean $n$-sphere $S^{n}$ according to whether $\lambda$ is zero or not.

CASE II. $\mathscr{C}$ has no interior point.
Then the set of non-umbilical points of $M$ is dense in $M$, i.e., $M=$ $\mathrm{Cl} \mathscr{N}$, the closure of $\mathscr{N}$. Around each point of $\mathscr{N}$, we take an adapted frame field $e_{A}$ so that

$$
\begin{align*}
& \omega_{i, n+1}=\lambda \omega_{i}  \tag{2}\\
& \omega_{n, n+1}=\mu \omega_{n} \tag{3}
\end{align*}
$$

as seen in $\S 1$. Here remark that $\lambda$ and $\mu$ are both analytic functions defined on $\mathscr{N}$ by virtue of the simple connectedness of $M$. Then from Lemma 2 (ii), with respect to each adapted frame field, we have $\lambda_{n} \mu_{j}=0$ for all $j$. Hence on $\mathscr{N}$ there can be the following three cases:
(A) For each adapted frame field, $\lambda_{n}$ as well as $\mu_{j}$ for all $j$ vanishes identically.
(B) For some adapted frame field, there exists a point $p \in \mathscr{N}$ such that $\mu_{j}(p) \neq 0$ for some $j$.
(C) For some adapted frame field, there exists a point $p \in \mathscr{N}$ such that $\lambda_{n}(p) \neq 0$.

Remark. Note that these three cases cover every possibility on $\mathscr{N}$. Moreover, in the course of the proof, it will turn out that (B) and (C) cannot hold simultaneously.

First we consider
$C A S E$ II-A. For each adapted frame field, $\lambda_{n}$ as well as $\mu_{j}$ for all $j$ vanishes identically.

In this case, since $d \lambda=\sum \lambda_{j} \omega_{j}+\lambda_{n} \omega_{n}=0$ at each point of $\mathscr{N}, \lambda$ is constant on each connected component of $\mathscr{N}$ and hence on a dense subset
$\mathscr{N}$ itself by continuity of $\lambda$. Furthermore, from Lemma 2(i), we have

$$
\begin{equation*}
\omega_{i n}=0 \tag{4}
\end{equation*}
$$

for each adapted frame field. Consequently, taking exterior differentiation of (4), we get

$$
\begin{equation*}
\lambda \mu=0 \quad \text { on } \quad \mathscr{N} . \tag{5}
\end{equation*}
$$

If $\lambda$ is a non-zero constant, then from (5), $\mu$ must vanish identically on $\mathscr{N}$. Therefore, $\mathscr{N}$ is a closed subset of $M$, which is also a non-empty open subset of $M$. Thus $\mathscr{N}$ coincides with $M$ by connectedness of $M$. Hence we can conclude that $f(M)$ is of the form

$$
S^{n-1} \times E^{1}
$$

the Riemannian product of a Euclidean $(n-1)$-sphere $S^{n-1}$ and a straight line $E^{1}$.

In case $\lambda$ vanishes identically on $\mathscr{N}$, we see immediately from the equation of Gauss that $M$ is flat on $\mathscr{N}$. Then $M$ itself is flat on account of the continuity of the Riemannian curvature tensor field, which is in fact an analytic tensor field on $M$. Thus, by a theorem of Hartman [2], $f(M)$ is a cylinder built over an analytic plane curve $\gamma$, i.e., of the form $E^{n-1} \times \gamma$.
$C A S E$ II-B. For some adapted frame field, there exists a point $p \in$ $\mathscr{N}$ such that $\mu_{j}(p) \neq 0$ for some $j$.

First, choose and fix such an adapted frame field $e_{A}$ and such a point $p_{0} \in \mathscr{N}$ as well. Then, with respect to the $e_{A}$, we have an open connected neighborhood $V$ of $p_{0}$ in $\mathscr{N}$ such that $\mu_{j}$ never vanishes on $V$. Since we have $\lambda_{n} \mu_{j}=0$ on $V$ from Lemma 2 (ii), $\lambda_{n}$ must vanish identically on $V$. Hence $\lambda$ is constant on $V$ because $\lambda_{j}$ always vanishes. Consequently it is observed that $\lambda$ is constant on the connected component $\mathscr{N}_{0}$ of $p_{0}$ of $\mathscr{N}$ by analyticity of $\lambda$.

If $\lambda$ vanishes identically on $\mathscr{N}_{0}$, then $M$ is flat on $\mathscr{N}_{0}$. Therefore, $M$ itself is flat because of the analyticity of the Riemannian curvature tensor field. Thus $f(M)$ is cylindrical over an analytic plane curve as seen in the previous case.

So from now on we assume that $\lambda$ is a non-zero constant on the component $\mathscr{N}_{0}$ of $\mathscr{N}$. Furthermore, we may assume $\lambda>0$ on $\mathscr{N}_{0}$ by replacing the unit normal vector field $e_{n+1}$ with $-e_{n+1}$ if necessary.

From Lemma 2 (i), we have for each adapted frame field on $\mathscr{N}_{0}$

$$
\begin{equation*}
\omega_{i n}=\left[\mu_{i} /(\lambda-\mu)\right] \omega_{n} \tag{6}
\end{equation*}
$$

because $\lambda_{n}$ vanishes identically on $\mathscr{N}_{0}$.
Taking exterior differentiation of (6), we get, with respect to each adapted frame field on $\mathscr{N}_{0}$, the following partial differential equation for each $i$ :

$$
\begin{equation*}
(\lambda-\mu) \mu_{i i}+2\left(\mu_{i}\right)^{2}+(\lambda-\mu)^{2} \lambda \mu=0 \tag{7}
\end{equation*}
$$

where we have put

$$
\mu_{i i}=d \mu_{i}\left(e_{i}\right)
$$

Let $M^{n-1}(p)$ denote the maximal integral submanifold through $p \in \mathscr{N}_{0}$ of the distribution defined by the space spanned by the principal vectors corresponding to $\lambda$. Then $M^{n-1}(p)$ is a totally geodesic submanifold of $M$, since (6) holds for each adapted frame field on $\mathscr{N}_{0}$ (cf. [4]). Therefore, we can restrict the above differential equation (7) to each geodesic of $M$ issuing from $p \in \mathscr{N}_{0}$ and tangent to $M^{n-1}(p)$ at $p$. Then along the geodesic we get the following ordinary differential equation

$$
\begin{equation*}
(\lambda-\mu) \frac{d^{2} \mu}{d s^{2}}+2\left(\frac{d \mu}{d s}\right)^{2}+(\lambda-\mu)^{2} \lambda \mu=0 \tag{8}
\end{equation*}
$$

where $s$ is the arc length from $p$.
Putting $\phi=1 /(\lambda-\mu)$, (8) reduces to

$$
\begin{equation*}
\frac{d^{2} \phi}{d s^{2}}+\lambda^{2} \phi-\lambda=0 \tag{9}
\end{equation*}
$$

By solving (9), we get

$$
\begin{equation*}
\phi=a \cos \lambda s+b \sin \lambda s+1 / \lambda \tag{10}
\end{equation*}
$$

where $a$ and $b$ are some constants of integration. Thus we obtain

$$
\begin{equation*}
\lambda-\mu=1 /(a \cos \lambda s+b \sin \lambda s+1 / \lambda), \tag{11}
\end{equation*}
$$

from which we have

$$
\begin{equation*}
\mu=\frac{\lambda(a \cos \lambda s+b \sin \lambda s)}{a \cos \lambda s+b \sin \lambda s+1 / \lambda} \tag{12}
\end{equation*}
$$

It is immediately verified from (11) that there does not exist any umbilical point on each geodesic issuing from $p \in \mathscr{N}_{0}$ and tangent to $M^{n-1}(p)$ at $p$ as well.

Furthermore, we have
Lemma 3. In this case, $M$ is umbilic free, i.e., there exists no umbilical point on $M$.

Proof. It suffices to show that $\mathscr{N}_{0}$ is a closed subset of $M$, since
$\mathscr{N}_{0}$ is a non-empty open subset of a connected $M$. For this purpose, let $p_{0}$ be a point on $\partial \mathscr{N}_{0}$, the boundary of $\mathscr{N}_{0}$, and $\left\{p_{n}\right\}$ a sequence of points of $\mathscr{N}_{0}$ converging to $p_{0}$ : $\lim _{n \rightarrow \infty} p_{n}=p_{0}$. Let $\gamma_{n}$ be a geodesic issuing from $p_{n}$ whose initial vector coincides with the vector $e_{i}\left(p_{n}\right)$ for a fixed $i$.

Note that $\gamma_{n}$ always belongs to $\mathscr{N}_{0}$, since there is no umbilical point on $\gamma_{n}$ as remarked just before the lemma. Furthermore, it follows from (12) that for each $n$ there exists a point $q_{n}$ on $\gamma_{n}$ for which $\mu\left(q_{n}\right)=$ 0 holds.

Since $M_{\text {, }}$ is complete, we may assert that the sequence $\left\{\gamma_{n}\right\}$ and the sequence $\left\{q_{n}\right\}$ converge respectively to $\gamma_{0}$, a geodesic issuing from $p_{0}$, and $q_{0}$, a point on $\gamma_{0}$, by choosing respective subsequences suitably if necessary. Then we have $\mu\left(q_{0}\right)=\lim _{n \rightarrow \infty} \mu\left(q_{n}\right)=0$ by continuity of $\mu$, and hence $q_{0} \in$ $\mathscr{N}_{0}$. Furthermore, since $\gamma_{0}=\lim _{n \rightarrow \infty} \gamma_{n}, \gamma_{0}$ is tangent to $M^{n-1}\left(q_{0}\right)$ at $q_{0}$. Therefore, the remark just before the lemma implies that $p_{0}$ belongs to $\mathscr{N}_{0}$. This completes the proof.
q.e.d.

Remark. In this case, $\lambda \equiv$ constant $>\mu$ holds everywhere on $M$. In fact, we assume the contrary. Namely, assume that $\mu>\lambda \equiv$ constant $>0$ holds everywhere. From (12), along any geodesic in $M$, we have

$$
\mu=\frac{\lambda \sqrt{a^{2}+b^{2}} \sin (\lambda s+\Phi)}{\sqrt{a^{2}+b^{2}} \sin (\lambda s+\Phi)+1 / \lambda},
$$

where $\sin \Phi=a / \sqrt{a^{2}+b^{2}}, \cos \Phi=b / \sqrt{a^{2}+b^{2}}, a$ and $b$ are certain constants, and $s$ is the arc length from some point on the geodesic in question. Hence, if $\mu$ does not change its sign, $\mu$ must be zero, since $s$ can take all real numbers. This is a contradiction.

Proposition 4. If $M$ is of CASE II-B with $\lambda \equiv$ constant $>0$, then $f(M)$ is a tube.

Proof. Define a mapping $C: M \rightarrow E^{n+1}$ by

$$
\begin{equation*}
C(p)=f(p)+(1 / \lambda) e_{n+1}(p), p \in M \tag{13}
\end{equation*}
$$

which is evidently well-defined. Then we have

$$
\begin{align*}
d C & =\sum \omega_{i} \otimes e_{i}+\omega_{n} \otimes e_{n}+(1 / \lambda) d e_{n+1}  \tag{14}\\
& =(1-\mu / \lambda) \omega_{n} \otimes e_{n}
\end{align*}
$$

noticing (2), (3) and the constancy of $\lambda$. This shows that the image of $C$ can be parametrized by the canonical parameter of some integral curve of $e_{n}$, that is, the image is a curve in $E^{n+1}$, which is also denoted by $C$. Furthermore, the curve $C$ is regular because $\lambda>\mu$ everywhere. Since $\lambda$ is a positive constant, it is not difficult to see from these facts that
$f(M)$ is nothing but the total space of the normal sphere bundle of the curve $C$ with radius $1 / \lambda$. Therefore $f(M)$ is a tube. q.e.d.

Finally we deal with
CASE II-C. For some adapted frame field, there exists a point $p \in \mathscr{N}$ such that $\lambda_{n}(p) \neq 0$.

In this case, we may further assume that $\mu_{j}$ does vanish identically for each adapted frame field. In fact, otherwise Case II-C reduces to Case II-B so that $\lambda$ is constant on $M$. This is a contradiction.

Remark. Thus, from Lemma 2(i), we have for each adapted frame field

$$
\begin{equation*}
\omega_{i n}=\left[\lambda_{n} /(\lambda-\mu)\right] \omega_{i}, \tag{15}
\end{equation*}
$$

from which we get

$$
d \omega_{n}=0
$$

Therefore, for each adapted frame field, we can locally put $\omega_{n}=d s$, where $s$ is the canonical parameter of some integral curve (which is in fact a geodesic segment) of $e_{n}$.

We set

$$
\mathscr{N}^{\prime}=\{p \in \mathscr{N} \mid \lambda(p) \neq 0\}
$$

Note that $\mathscr{N}^{\prime}$ is dense in $\mathscr{N}$ and hence in $M$ as well, i.e., $M=\mathrm{Cl} \mathscr{N}^{\prime}$ because $\lambda$ is a non-constant analytic function.

We define a mapping $C: \mathscr{N}^{\prime} \rightarrow E^{n+1}$ by

$$
\begin{equation*}
C(p)=f(p)+(1 / \lambda)(p) e_{n+1}(p), p \in \mathscr{N}^{\prime} \tag{16}
\end{equation*}
$$

which is obviously well-defined. Then we have

$$
\begin{align*}
d C= & \sum \omega_{i} \otimes e_{i}+\omega_{n} \otimes e_{n}  \tag{17}\\
& +d\left(\frac{1}{\lambda}\right) \otimes e_{n+1}+\frac{1}{\lambda} d e_{n+1} \\
= & \left(1-\frac{\mu}{\lambda}\right) \omega_{n} \otimes e_{n}+\left(\frac{1}{\lambda}\right)^{\prime} \omega_{n} \otimes e_{n+1} \\
= & \left\{\left(1-\frac{\mu}{\lambda}\right) e_{n}+\left(\frac{1}{\lambda}\right)^{\prime} e_{n+1}\right\} d s,
\end{align*}
$$

where the prime denotes the differentiation with respect to $s$. This shows, by the same argument as in Case II-B, that the image of $C$ is a union of regular curves in $E^{n+1}$, which is also denoted by $C$.

Since, for each adapted frame field, $\lambda_{j}$ as well as $\mu_{j}$ does vanish
identically for all $j$, we can easily observe that $\mathscr{N}^{\prime}$ and hence its closure $M$ itself are (possibly a part of) the envelope of a one-parameter family of hyperspheres in $E^{n+1}$, and the curve $C$ is nothing but (possibly a part of) the locus of centers of such hyperspheres (cf. [4]).

Now we prove
Lemma 5. Each component of $C$ is a segment in $E^{n+1}$.
Proof. We put

$$
\xi=d C / d s=[(\lambda-\mu) / \lambda] e_{n}+(1 / \lambda)^{\prime} e_{n+1} .
$$

It suffices to show that at each point of $C$, two vectors $\xi$ and $d \xi / d s$ are parallel. By making use of (15), we see

$$
\begin{align*}
d \xi & =\left(\frac{\lambda-\mu}{\lambda}\right)^{\prime} \omega_{n} \otimes e_{n}+\left(\frac{1}{\lambda}\right)^{\prime \prime} \omega_{n} \otimes e_{n+1}  \tag{18}\\
& +\frac{\lambda-\mu}{\lambda} d e_{n}+\left(\frac{1}{\lambda}\right)^{\prime} d e_{n+1} \\
& =\left[\left\{\left(\frac{\lambda-\mu}{\lambda}\right)^{\prime}-\left(\frac{1}{\lambda}\right)^{\prime} \mu\right\} e_{n}+\left\{\left(\frac{1}{\lambda}\right)^{\prime \prime}+\frac{(\lambda-\mu) \mu}{\lambda}\right\} e_{n+1}\right] d s .
\end{align*}
$$

On the other hand, taking exterior differentiation of (15), we get

$$
\begin{equation*}
\left(\frac{\lambda^{\prime}}{\lambda-\mu}\right)^{\prime}-\left(\frac{\lambda^{\prime}}{\lambda-\mu}\right)^{2}-\lambda \mu=0 \tag{19}
\end{equation*}
$$

from which we obtain the following relation

$$
\begin{equation*}
\left(\frac{1}{\lambda}\right)^{\prime}\left\{\left(\frac{\lambda-\mu}{\lambda}\right)^{\prime}-\left(\frac{1}{\lambda}\right)^{\prime} \mu\right\}=\frac{\lambda-\mu}{\lambda}\left\{\left(\frac{1}{\lambda}\right)^{\prime \prime}+\frac{(\lambda-\mu) \mu}{\lambda}\right\}, \tag{20}
\end{equation*}
$$

because (19) and (20) are both equivalent to

$$
\begin{equation*}
\lambda^{\prime \prime}(\lambda-\mu)-\lambda^{\prime}\left(2 \lambda^{\prime}-\mu^{\prime}\right)-\lambda \mu(\lambda-\mu)^{2}=0 \tag{21}
\end{equation*}
$$

Here the relation (20) shows that at each point of $C$, two vectors $\xi$ and $d \xi / d s$ are parallel. This completes the proof. q.e.d.

Consequently, we have
Proposition 6. If $M$ is of CASE II-C, then $f(M)$ is a surface of revolution.

Proof. We have only to prove that the curve $C$ lies on a straight line. However, it is almost obvious now, since $f(M)$ is an analytic hypersurface in $E^{n+1}$, and the set $\mathscr{N}^{\prime}$ is dense in $M$, i.e., $M=\mathrm{Cl} \mathscr{N}^{\prime}$. q.e.d.

Remark. It should be noted here that $f(M)$ is called a surface of
revolution in the following sense: $f(M)$ is obtained by the analytic glueing of some surfaces of revolution defined in $\S 1$ such that each of the loci of their centers lies on the same straight line.

Summerizing the above results, we arrive at
THEOREM 7. Let $(M, g)$ be an analytic complete conformally flat Riemannian n-manifold, $n>3$, and $f: M \rightarrow E^{n+1}$ an analytic isometric immersion of $M$ into a Euclidean $(n+1)$-space. Then $f(M)$ is one of the following: (i) a flat hypersurface, (ii) a tube and (iii) a surface of revolution.
