## 1. Introduction.

Let $S^{3}$ be the unit hypersphere in the 4 -dimensional Euclidean space $E^{4}$ given by $\sum_{i=1}^{4} x_{i}^{2}=1$. For each $\theta$ with $0<\theta<\pi / 2$, we consider a surface $M_{\theta}$ in $S^{3}$ defined by

$$
x_{1}^{2}+x_{2}^{2}=\cos ^{2} \theta, \quad x_{3}^{2}+x_{4}^{2}=\sin ^{2} \theta .
$$

The surface $M_{\theta}$, which is called a Clifford torus in $S^{3}$, can be viewed as an embedded flat torus in $S^{3}$. There are many other examples of embedded flat tori in $S^{3}$. Let $p: S^{3} \rightarrow S^{2}$ be the Hopf fibration, and let $\gamma$ be a simple closed curve in $S^{2}$. Then it is known [4] that the inverse image $p^{-1}(\gamma)$ is an embedded flat torus in $S^{3}$. Note that $p^{-1}(\gamma)$ is foliated by great circles of $S^{3}$, and so it satisfies the antipodal symmetry, i.e., it is invariant under the antipodal map of $S^{3}$. Recently the author [2] obtained another example of embedded flat tori in $S^{3}$. Although this example contains no great circle of $S^{3}$, it also satisfies the antipodal symmetry. In this paper we show that the antipodal symmetry holds for all embedded flat tori in $S^{3}$. In other words, we prove the following theorem.

Theorem 1.1. If $f: M \rightarrow S^{3}$ is an isometric embedding of a flat torus $M$ into $S^{3}$, then the image $f(M)$ is invariant under the antipodal map of $S^{3}$.

Remark. In Theorem 1.1 the word "embedding" cannot be replaced by "immersion". In fact, Theorem 4.4 says that there exists a flat torus $M$ and an isometric immersion $f: M \rightarrow S^{3}$ such that the image $f(M)$ is not invariant under the antipodal map of $S^{3}$. However the author does not know the answer to the following question: For every isometric immersion $f$ of a flat torus $M$ into $S^{3}$, does there exist a pair of points $p$ and $q$ in $M$ such that $f(p)$ and $f(q)$ are antipodal points of $S^{3}$ ?

The outline of this paper is as follows. Let $S U(2)$ be the group of all $2 \times 2$ unitary matrices with determinant 1 . Then $S U(2)$, endowed with a bi-invariant metric, is isometric to $S^{3}$. Using the group structure on $S^{3}$, we define a
double covering $p_{2}: S^{3} \rightarrow U S^{2}$, where $U S^{2}$ denotes the unit tangent bundle of $S^{2}$. The double covering $p_{2}$ satisfies $p_{2}(a)=p_{2}(-a)$ for all $a \in S^{3}$. For each regular curve $\gamma$ in $S^{2}$, define a curve $\hat{\gamma}$ in $U S^{2}$ by $\hat{\gamma}=\dot{\gamma} /\|\dot{\gamma}\|$. In Section 2 we study the behavior of a curve $c$ in $S^{3}$ satisfying the relation $p_{2}(c)=\hat{\gamma}$.

In Section 3 we explain a method for constructing all the flat tori in $S^{3}$. A pair $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ of periodic regular curves $\gamma_{i}: \boldsymbol{R} \rightarrow S^{2}$ is said to be a periodic admissible pair if the geodesic curvature of $\gamma_{1}$ is greater than that of $\gamma_{2}$ and some auxiliary conditions are satisfied. For each periodic admissible pair $\Gamma=$ ( $\gamma_{1}, \gamma_{2}$ ), using the group structure on $S^{3}$, we define an immersion $F_{\Gamma}: \boldsymbol{R}^{2} \rightarrow S^{3}$ by

$$
\begin{equation*}
F_{\Gamma}\left(s_{1}, s_{2}\right)=c_{1}\left(s_{1}\right) \cdot c_{2}\left(s_{2}\right)^{-1} \tag{1.1}
\end{equation*}
$$

where $c_{i}$ denotes a lift of $\hat{\gamma}_{i}$ with respect to $p_{2}$. The immersion $F_{\Gamma}$ induces a flat Riemannian metric $g_{\Gamma}$ on $\boldsymbol{R}^{2}$. Define $G(\Gamma)$ to be the group of all diffeomorphisms $\rho$ of $\boldsymbol{R}^{2}$ satisfying $F_{\Gamma^{\circ}} \rho=F_{\Gamma}$. Then we obtain a flat torus $M_{\Gamma}=$ $\left(\boldsymbol{R}^{2}, g_{\Gamma}\right) / G(\Gamma)$ and an isometric immersion $f_{\Gamma}: M_{\Gamma} \rightarrow S^{3}$ such that $f_{\Gamma}{ }^{\circ} \pi=F_{\Gamma}$, where $\pi$ denotes the canonical projection of $\boldsymbol{R}^{2}$ onto $M_{\Gamma}$. Note that the immersion $f_{\Gamma}$ is primitive, i. e., the identity map of $M_{\Gamma}$ is the only diffeomorphism $\varphi: M_{\Gamma} \rightarrow M_{\Gamma}$ satisfying $f_{\Gamma}{ }^{\circ} \varphi=f_{\Gamma}$. Conversely, we show that if $f: M \rightarrow S^{3}$ is a primitive isometric immersion of a flat torus $M$ into $S^{3}$, then there exists a periodic admissible pair $\Gamma$ such that $f$ and $f_{\Gamma}$ are congruent Theorem 3.1).

For each periodic admissible pair $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$, the group $G(\Gamma)$ can be identified with a lattice in $\boldsymbol{R}^{2}$. In Section 4 we study generators of the lattice $G(\Gamma)$. Let $l_{i}>0$ be the minimum period of $\gamma_{i}$, and let $I\left(\gamma_{i}\right)$ be the element of the homology group $H_{1}\left(U S^{2}\right)$ represented by the closed curve $\hat{\gamma}_{i} \mid\left[0, l_{i}\right]$. Note that $H_{1}\left(U S^{2}\right) \cong \boldsymbol{Z}_{2}$ and

$$
\begin{equation*}
c_{i}\left(s+l_{i}\right)=-c_{i}(s) \quad \text { if } \quad I\left(\gamma_{i}\right)=1 \tag{1.2}
\end{equation*}
$$

where $c_{i}$ denotes a lift of $\hat{r}_{i}$ with respect to $p_{2}$. We show that generators of $G(\Gamma)$ can be written in terms of $l_{i}$ and $I\left(\gamma_{i}\right)$ Theorem 4.1).

In Section 5 we study asymptotic curves of embedded flat tori in $S^{3}$, and prove Theorem 1.1. Let $M$ be a flat torus isometrically embedded in $S^{3}$ with a unit normal vector field $\xi$. We consider a unit speed asymptotic curve $c: \boldsymbol{R} \rightarrow M$. Then there exists a positive number $l$ such that $c(s+l)=c(s)$ and $c \mid[0, l]$ is a simple closed curve Theorem 5.1). Let $\alpha=c \mid[0, l]$, and let $\alpha^{+}$be a $\lambda$ curve in $S^{3}-M$ obtained by pushing $\alpha$ a very small amount along the unit normal vector field $\xi$. Then we show that the linking number of $\alpha$ and $\alpha^{+}$is odd Theorem 5.2). To establish Theorem 5.2 we need a lemma which is stated in Section 2 without proof. The proof of this lemma will be given in Section 6.

We now sketch the proof of Theorem 1.1. Let $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ be a periodic admissible pair such that $f_{\Gamma}: M_{\Gamma} \rightarrow S^{3}$ is an embedding. Consider a disk $D \subset M_{\Gamma}$
and define a knot $K$ in $S^{3}$ by setting $K=f_{\Gamma}(\partial D)$. Since $K$ is unknotted, the Arf invariant of $K$ vanishes, i.e., $\operatorname{Arf}(K)=0$. We set $V=f_{\Gamma}\left(M_{\Gamma}-D\right)$. Then $V$ is a Seifert surface of $K$, and so $\operatorname{Arf}(K)$ can be computed by using a canonical basis of the homology group $H_{1}(V)$. Unless $I\left(\gamma_{1}\right)=I\left(\gamma_{2}\right)=1$, it follows from Theorem 4. 1 that a canonical basis of $H_{1}(V)$ can be represented by asymptotic curves of $M_{\Gamma}$. So Theorem 5.2 implies $\operatorname{Arf}(K)=1$. This shows that the periodic admissible pair $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ must satisfy $I\left(\gamma_{1}\right)=I\left(\gamma_{2}\right)=1$. Therefore it follows from (1.1) and (1.2) that the image of the embedding $f_{\Gamma}$ is invariant under the antipodal map of $S^{3}$. Hence the assertion of Theorem 1.1 follows from Theorem 3.1.

In the final section we compute the Gauss map of the immersion $F_{\Gamma}: \boldsymbol{R}^{2} \rightarrow S^{3}$. The result of this computation will help us to understand the relation between the construction explained in Section 3 and another one which was established in the recent works of Weiner [7], [8].

The author is deeply grateful to Professor S. Tanno for his constant encouragement.

## 2. Preliminaries.

Let $S U(2)$ be the group of all $2 \times 2$ unitary matrices with determinant 1 . Its Lie algebra $\mathfrak{h u}(2)$ consists of all $2 \times 2$ skew Hermitian matrices of trace 0 . The adjoint representation $\operatorname{Ad}$ of $S U(2)$ is given by $\operatorname{Ad}(a) x=a \cdot x \cdot a^{-1}$, where $a \in S U(2)$ and $x \in \mathfrak{h u}(2)$. For $x, y \in \mathfrak{Z u}(2)$, we set $\langle x, y\rangle=-(1 / 2)$ trace $(x y)$. Then $\langle$,$\rangle is a positive definite inner product on \mathfrak{z u}(2)$ which is invariant under Ad. We set

$$
e_{1}=\left[\begin{array}{cc}
0 & \sqrt{-1} \\
\sqrt{-1} & 0
\end{array}\right], \quad e_{2}=\left[\begin{array}{cc}
0 & -1 \\
1 & 0
\end{array}\right], \quad e_{3}=\left[\begin{array}{cc}
\sqrt{-1} & 0 \\
0 & -\sqrt{-1}
\end{array}\right] .
$$

Then $\left\{e_{1}, e_{2}, e_{3}\right\}$ is an orthonormal basis of $\mathfrak{h u}(2)$. Note that

$$
\left[e_{1}, e_{2}\right]=2 e_{3}, \quad\left[e_{2}, e_{3}\right]=2 e_{1}, \quad\left[e_{3}, e_{1}\right]=2 e_{2},
$$

where [,] denotes the Lie bracket on $\mathfrak{B u}(2)$. Let $E_{i}$ be a left invariant vector field on $S U(2)$ which corresponds to $e_{i}$. We endow $S U(2)$ with a Riemannian metric and an orientation such that $\left\{E_{1}, E_{2}, E_{3}\right\}$ is a positive orthonormal frame field. Then $S U(2)$ is a Riemannian manifold isometric to the unit 3 -sphere $S^{3}$. Henceforth, we identify $S^{3}$ with $S U(2)$.

Let $S^{2}$ be the unit 2 -sphere in $\mathfrak{z u}(2)$ given by $S^{2}=\{x \in \mathfrak{G u}(2):\|x\|=1\}$, and let $p: S^{3} \rightarrow S^{2}$ be the Hopf fibration defined by $p(a)=\operatorname{Ad}(a) e_{3}$. Note that the fibers of the Hopf fibration $p$ coincide with the integral curves of the vector field $E_{3}$. We identify $U S^{2}$, the unit tangent bundle of $S^{2}$, with a subset of $\mathfrak{s} \mathfrak{u}(2) \times \mathfrak{h} \mathfrak{u}(2)$ in the usual way, i.e.,

$$
U S^{2}=\{(x, y):\|x\|=\|y\|=1,\langle x, y\rangle=0\},
$$

and the canonical projection $p_{1}: U S^{2} \rightarrow S^{2}$ is given by $p_{1}(x, y)=x$.
Lemma 2.1. Let $\gamma(s)$ be a curve in $S^{2}$ defined by $\gamma(s)=p(\exp (s v))$, where $v=a_{1} e_{1}+a_{2} e_{2}$. For $i=1,2$, let $\xi_{i}(s)=\left(\gamma(s), \operatorname{Ad}(\exp (s v)) e_{i}\right) \in U S^{2}$. Then $\xi_{i}$ is a parallel vector field along $\gamma$.

Proof. We set $u_{i}(s)=\operatorname{Ad}(\exp (s v)) e_{i}$. Then $u_{i}^{\prime}(s)=\operatorname{Ad}(\exp (s v))\left[v, e_{i}\right]$. Since $\left[v, e_{i}\right]=t e_{3}$ for some $t$, we obtain $u_{i}^{\prime}(s)=t \gamma(s)$. This shows the assertion of Lemma 2.1.
Q.E.D.

Define a map $p_{2}: S^{3} \rightarrow U S^{2}$ by

$$
\begin{equation*}
p_{2}(a)=\left(\operatorname{Ad}(a) e_{3}, \operatorname{Ad}(a) e_{1}\right) . \tag{2.1}
\end{equation*}
$$

Then $p=p_{1} \circ p_{2}$, and $p_{2}$ is a double covering such that $p_{2}(a)=p_{2}(-a)$ for all $a \in S^{3}$. We consider a regular curve $\gamma(s)$ in $S^{2}$. Its geodesic curvature $k(s)$ is given by

$$
k(s)=\left\langle\gamma^{\prime \prime}(s), J\left(\gamma^{\prime}(s)\right)\right\rangle /\left\|\gamma^{\prime}(s)\right\|^{3},
$$

where $J: T_{x} S^{2} \rightarrow T_{x} S^{2}$ denotes a complex structure given by $J(v)=[x, v] / 2$. We define a curve $\hat{\gamma}(s)$ in $U S^{2}$ by

$$
\begin{equation*}
\hat{\gamma}(s)=\left(\gamma(s), \gamma^{\prime}(s) /\left\|\gamma^{\prime}(s)\right\|\right) . \tag{2.2}
\end{equation*}
$$

Since $p_{2}$ is a covering, there exists a curve $c(s)$ in $S^{3}$ such that $p_{2}(c(s))=\hat{\gamma}(s)$.
Lemma 2.2. $\dot{c}(s)=(1 / 2)\left\|\gamma^{\prime}(s)\right\|\left\{E_{2}(c(s))+k(s) E_{3}(c(s))\right\}$.
Proof. We set $\dot{c}(s)=\sum_{i=1}^{3} f_{i}(s) E_{i}(c(s))$. Then we obtain

$$
\begin{equation*}
\frac{d}{d s}\left\{\operatorname{Ad}(c) e_{j}\right\}=\operatorname{Ad}(c)\left[\sum_{i=1}^{3} f_{i} e_{i}, e_{j}\right] \tag{2.3}
\end{equation*}
$$

Since $p_{2}(c)=\hat{\gamma}$, we have (2.4)-(2.6).

$$
\begin{gather*}
\frac{d}{d s}\left\{\operatorname{Ad}(c) e_{3}\right\}=\left\|\gamma^{\prime}\right\| \operatorname{Ad}(c) e_{1}  \tag{2.4}\\
\left\langle\frac{d}{d s}\left\{\operatorname{Ad}(c) e_{1}\right\}, J\left(\gamma^{\prime}\right)\right\rangle=k\left\|\gamma^{\prime}\right\|^{2},  \tag{2.5}\\
J\left(\gamma^{\prime}\right)=\left\|\gamma^{\prime}\right\| \operatorname{Ad}(c) e_{2} \tag{2.6}
\end{gather*}
$$

By (2.3) and (2.4) we see that $\left\|\gamma^{\prime}\right\| e_{1}=-2 f_{1} e_{2}+2 f_{2} e_{1}$, and so $f_{1}=0$ and $f_{2}=$ $\left\|\boldsymbol{\gamma}^{\prime}\right\| / 2$. Furthermore it follows from (2.3), (2.5) and (2.6) that $f_{3}=k\left\|\gamma^{\prime}\right\| / 2$.
Q.E.D.

Let $\gamma: \boldsymbol{R} \rightarrow S^{2}$ be a regular curve with a period $l>0$, and let $c: \boldsymbol{R} \rightarrow S^{3}$ be a
lift of $\hat{\gamma}$ with respect to the covering $p_{2}$. We define $\omega$ to be the element of the homology group $H_{1}\left(U S^{2}\right)$ represented by the closed curve $\hat{\gamma} \mid[0, l]$. Note that $U S^{2}$ is homeomorphic to the real projective space $P^{3}$, and so $H_{1}\left(U S^{2}\right) \cong Z_{2}$. Since $p_{2}$ is a double covering with $p_{2}(a)=p_{2}(-a)$, it is easy to see that

$$
c(s+l)=\left\{\begin{align*}
c(s) & \text { if } \omega=0,  \tag{2.7}\\
-c(s) & \text { if } \omega=1 .
\end{align*}\right.
$$

We now assume that $c(s+l)=c(s)$ and $c \mid[0, l]$ is a simple closed curve. Let $b=c \mid[0, l]$, and let $\varphi^{t}$ be the 1-parameter group of diffeomorphisms of $S^{3}$ generated by the vector field $E_{3}$. Since $\dot{b}(s)$ and $E_{3}(b(s))$ are linearly independent, there exists a positive number $\delta$ such that $\varphi^{t}(b)$ does not intersect $b$ for all $t$ with $0<t \leqq \delta$. Define $\operatorname{lk}\left(b, E_{3}\right)$ to be the linking number $1 \mathrm{k}\left(b, \varphi^{\delta}(b)\right)$, which does not depend on the choice of $\delta$. We refer the reader to [6, p. 132] for the definition of the linking numbers. The following lemma, which will be proved in Section 6, plays an important role in the proof of Theorem 5.2.

Lemma 2.3. $1 \mathrm{k}\left(b, E_{3}\right) \equiv 1(\bmod 2)$.

## 3. Construction of flat tori in $S^{3}$.

In this section we explain a method for constructing flat tori in $S^{3}$ established in [2]. Let $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ be a pair of regular curves $\gamma_{i}: \boldsymbol{R} \rightarrow S^{2}$. The pair $\Gamma$ is said to be an admissible pair if it satisfies the following conditions (3.1)(3.3).

$$
\begin{gather*}
\hat{\gamma}_{i}(0)=\left(e_{3}, e_{1}\right)  \tag{3.1}\\
\left\|\boldsymbol{\gamma}_{i}^{\prime}\right\|^{2}\left(1+k_{i}^{2}\right)=4  \tag{3.2}\\
k_{1}\left(s_{1}\right)>k_{2}\left(s_{2}\right) \quad \text { for all }\left(s_{1}, s_{2}\right) \in \boldsymbol{R}^{2} \tag{3.3}
\end{gather*}
$$

where $k_{i}$ denotes the geodesic curvature of $\gamma_{i}$. Let $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ be an admissible pair. For each $i$, it follows from (2.1) and (3.1) that there exists a curve $c_{i}: \boldsymbol{R} \rightarrow S^{3}$ such that $p_{2}\left(c_{i}\right)=\hat{\gamma}_{i}$ and $c_{i}(0)=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. Using the group structure on $S^{3}$, we define a map $F_{\Gamma}: \boldsymbol{R}^{2} \rightarrow S^{3}$ by

$$
\begin{equation*}
F_{\Gamma}\left(s_{1}, s_{2}\right)=c_{1}\left(s_{1}\right) \cdot c_{2}\left(s_{2}\right)^{-1} \tag{3.4}
\end{equation*}
$$

It follows from [2, Lemma 3.8 and Theorem 4.2] that $F_{\Gamma}$ is a FAT. Here we recall the following definition.

Definition. An immersion $F: \boldsymbol{R}^{2} \rightarrow S^{3}$ is said to be a $F A T$ if $F$ induces a flat Riemannian metric $g$ on $\boldsymbol{R}^{2}$ and

$$
g\left(\frac{\partial}{\partial s_{i}}, \frac{\partial}{\partial s_{i}}\right)=1, \quad h\left(\frac{\partial}{\partial s_{i}}, \frac{\partial}{\partial s_{i}}\right)=0 \quad(i=1,2),
$$

where $h$ denotes the second fundamental form of $F$.
Let $g_{\Gamma}$ be a flat Riemannian metric on $\boldsymbol{R}^{2}$ induced by $F_{\Gamma}$, and let $G(\Gamma)$ be a group defined by

$$
G(\Gamma)=\left\{\rho \in \operatorname{Diff}\left(\boldsymbol{R}^{2}\right): F_{\Gamma^{\circ}} \rho=F_{\Gamma}\right\}
$$

where Diff ( $\boldsymbol{R}^{2}$ ) denotes the group of all diffeomorphisms of $\boldsymbol{R}^{2}$. Then we obtain a 2-dimensional flat Riemannian manifold $M_{\Gamma}=\left(\boldsymbol{R}^{2}, g_{\Gamma}\right) / G(\Gamma)$ and an isometric immersion $f_{\Gamma}: M_{\Gamma} \rightarrow S^{3}$ such that $f_{\Gamma} \pi_{\Gamma}=F_{\Gamma}$, where $\pi_{\Gamma}$ denotes the canonical projection of $\boldsymbol{R}^{2}$ onto $M_{\Gamma}$. It is easy to see that the immersion $f_{\Gamma}: M_{\Gamma} \rightarrow S^{3}$ is primitive. Here we give the following definition.

Definition. Let $X$ and $Y$ be smooth manifolds, and let $f: X \rightarrow Y$ be an immersion. The immersion $f$ is said to be primitive if the identity map of $X$ is the only diffeomorphism $\varphi: X \rightarrow X$ such that $f \circ \varphi=f$.

Since $F_{\Gamma}$ is a FAT, it follows from [2, Theorem 2.3] that the group $G(\Gamma)$ consists of parallel translations of $\boldsymbol{R}^{2}$, and so $M_{\Gamma}$ is orientable. Furthermore it follows from [2, Theorem 5.1] that $M_{\Gamma}$ is compact if and only if $\Gamma$ is periodic. Here $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ is said to be periodic if $\gamma_{1}$ and $\gamma_{2}$ are periodic. So we see that a periodic admissible pair $\Gamma$ induces a flat torus $M_{\Gamma}$ and a primitive isometric immersion $f_{\Gamma}: M_{\Gamma} \rightarrow S^{3}$. Conversely, we obtain the following theorem.

Theorem 3.1. Let $f: M \rightarrow S^{3}$ be a primitive isometric immersion of a flat torus $M$ into $S^{3}$. Then there exists a periodic admissible pair $\Gamma$ such that $f$ and $f_{\Gamma}$ are congruent, i.e., there exists an isometry $A$ of $S^{3}$ which satisfies $A \circ f=$ $f_{\Gamma^{\circ}} \rho$ for some diffeomorphism $\rho: M \rightarrow M_{\Gamma}$.

Proof. It follows from [3] that there exists a covering $T: \boldsymbol{R}^{2} \rightarrow M$ such that $f \circ T$ is a FAT. Then it follows from [2, Theorem 4.3] that there exists an admissible pair $\Gamma$ such that $F_{\Gamma}=A \circ f \circ T$ for some isometry $A$ of $S^{3}$. It is easy to see that the covering transformation group of $T$ is contained in $G(\Gamma)$. Hence there exists a covering $\rho: M \rightarrow M_{\Gamma}$ such that $\rho \circ T=\pi_{\Gamma}$. This implies that $M_{\Gamma}$ is compact, and so the admissible pair $\Gamma$ is periodic. Since the fundamental group of $M_{\Gamma}$ is isomorphic to the abelian group $G(\Gamma)$, the covering $\rho$ is normal. Furthermore the covering transformation group of $\rho$ is trivial because $f$ is primitive and $A \circ f=f_{\Gamma^{\circ}} \rho$. Hence the covering $\rho$ must be a diffeomorphism.
Q.E.D.

Corollary 3.2. If $f: M \rightarrow S^{3}$ is an isometric embedding of a flat torus $M$
into $S^{3}$, then there exists a periodic admissible pair $\Gamma$ such that $f$ and $f_{\Gamma}$ are congruent.

We conclude this section with two lemmas.
Lemma 3.3 ([2, Lemma 5.5]). Let $\Gamma=\left(\boldsymbol{\gamma}_{1}, \boldsymbol{\gamma}_{2}\right)$ be an admissible pair, and let $\left(l_{1}, l_{2}\right) \in \boldsymbol{R}^{2}$. If the immersion $F_{\Gamma}: \boldsymbol{R}^{2} \rightarrow S^{3}$ satisfies $F_{\Gamma}\left(s_{1}, s_{2}\right)=F_{\Gamma}\left(s_{1}+l_{1}, s_{2}+l_{2}\right)$, then $\gamma_{i}\left(s+l_{i}\right)=\gamma_{i}(s)$ for $i=1,2$.

Lemma 3.4. Let $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ be an admissible pair, and let $\eta$ be a unit normal vector field along $F_{\Gamma}$. Then $\eta$ is orthogonal to $E_{2}$ and $E_{3}$ along the curve $F_{\Gamma}(s, 0)$.

Proof. Let $c_{i}: \boldsymbol{R} \rightarrow S^{3}$ be a curve such that $p_{2}\left(c_{i}\right)=\hat{\gamma}_{i}$ and $c_{i}(0)=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. By (3.4) we obtain

$$
\partial_{1} F_{\Gamma}(s, 0)=\dot{c}_{1}(s), \quad \partial_{2} F_{\Gamma}(s, 0)=\left\{L_{c_{1}(s)}\right\}_{*}\left(-\dot{c}_{2}(0)\right)
$$

where $\partial_{i}=\partial / \partial s_{i}$. So the assertion of Lemma 3.4 follows from Lemma 2.2. Q.E.D.

## 4. Generators of $G(\Gamma)$.

Let $\Gamma$ be a periodic admissible pair. Since the group $G(\Gamma)$ consists of parallel translations of $\boldsymbol{R}^{2}$ and the quotient space $\boldsymbol{R}^{2} / G(\Gamma)$ is compact, the group $G(\Gamma)$ can be identified with a lattice in $\boldsymbol{R}^{2}$ in the natural way. In this section we study generators of the lattice $G(\Gamma)$. Let $\gamma: \boldsymbol{R} \rightarrow S^{2}$ be a periodic regular curve, and let $l>0$ be the minimum period of $\gamma$. Recall the curve $\hat{\gamma}: \boldsymbol{R} \rightarrow U S^{2}$ given by (2.2), and define $I(\gamma)$ to be the element of the homology group $H_{1}\left(U S^{2}\right)$ represented by the closed curve $\hat{\gamma} \mid[0, l]$.

Theorem 4.1. Let $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ be a periodic admissible pair, and let $l_{i}>0$ be the minimum period of $\gamma_{i}$. Then the lattice $G(\Gamma)$ has the following generators:
(1) $\left(l_{1}, 0\right),\left(0, l_{2}\right) \quad$ if $I\left(\gamma_{1}\right)=0, I\left(\gamma_{2}\right)=0$,
(2) $\left(2 l_{1}, 0\right),\left(0, l_{2}\right) \quad$ if $I\left(\gamma_{1}\right)=1, I\left(\gamma_{2}\right)=0$,
(3) $\left(l_{1}, 0\right),\left(0,2 l_{2}\right)$ if $I\left(\gamma_{1}\right)=0, I\left(\gamma_{2}\right)=1$,
(4) $\left(l_{1}, l_{2}\right),\left(l_{1},-l_{2}\right) \quad$ if $I\left(\gamma_{1}\right)=1, I\left(\gamma_{2}\right)=1$.

PRoof. Let $c_{i}: \boldsymbol{R} \rightarrow S^{3}$ be a curve such that $p_{2}\left(c_{i}\right)=\hat{\gamma}_{i}$ and $c_{i}(0)=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. Then it follows from (2.7) that

$$
c_{i}\left(s+l_{i}\right)=\left\{\begin{align*}
c_{i}(s) & \text { if } I\left(\gamma_{i}\right)=0  \tag{4.1}\\
-c_{i}(s) & \text { if } I\left(\gamma_{i}\right)=1
\end{align*}\right.
$$

Suppose that $I\left(\gamma_{1}\right)=I\left(\gamma_{2}\right)=0$. Then it follows from (3.4) and (4.1) that

$$
F_{\Gamma}\left(s_{1}+l_{1}, s_{2}\right)=F_{\Gamma}\left(s_{1}, s_{2}\right)=F_{\Gamma}\left(s_{1}, s_{2}+l_{2}\right) .
$$

Hence the lattice $G(\Gamma)$ contains $\left(l_{1}, 0\right)$ and $\left(0, l_{2}\right)$. Let $x_{1}$ and $x_{2}$ be real numbers such that

$$
x_{1}\left(l_{1}, 0\right)+x_{2}\left(0, l_{2}\right) \in G(\Gamma) .
$$

Then Lemma 3.3 implies $\gamma_{i}\left(s+x_{i} l_{i}\right)=\gamma_{i}(s)$. So it follows from the definition of $l_{i}$ that $x_{1}$ and $x_{2}$ are integers. This proves (1).

Suppose that $I\left(\gamma_{1}\right)=1$ and $I\left(\gamma_{2}\right)=0$. Then it follows from (3.4) and (4.1) that

$$
F_{\Gamma}\left(s_{1}+2 l_{1}, s_{2}\right)=F_{\Gamma}\left(s_{1}, s_{2}\right)=F_{\Gamma}\left(s_{1}, s_{2}+l_{2}\right) .
$$

Hence the lattice $G(\Gamma)$ contains $\left(2 l_{1}, 0\right)$ and $\left(0, l_{2}\right)$. Let $x_{1}$ and $x_{2}$ be real numbers such that

$$
\begin{equation*}
x_{1}\left(2 l_{1}, 0\right)+x_{2}\left(0, l_{2}\right) \in G(\Gamma) . \tag{4.2}
\end{equation*}
$$

To establish (2) it is sufficient to show that $x_{1}$ and $x_{2}$ are integers. We may assume that $0 \leqq x_{i}<1$. It follows from (4.2) and Lemma 3.3 that $2 x_{1} l_{1}$ and $x_{2} l_{2}$ are periods of $\gamma_{1}$ and $\gamma_{2}$, respectively. So it follows from the definition of $l_{i}$ that $2 x_{1}$ and $x_{2}$ are integers. Hence $\left(x_{1}, x_{2}\right)=(0,0)$ or $(1 / 2,0)$. We now consider the case $\left(x_{1}, x_{2}\right)=(1 / 2,0)$. By (4.2) we have $\left(l_{1}, 0\right) \in G(\Gamma)$, and so $F_{\Gamma}\left(s_{1}+l_{1}, s_{2}\right)=F_{\Gamma}\left(s_{1}, s_{2}\right)$. However it follows from (3.4), (4.1) and the assumption $I\left(\gamma_{1}\right)=1$ that

$$
F_{\Gamma}\left(s_{1}+l_{1}, s_{2}\right)=-c_{1}\left(s_{1}\right) \cdot c_{2}\left(s_{2}\right)^{-1}=-F_{\Gamma}\left(s_{1}, s_{2}\right) .
$$

Hence we have $F_{\Gamma}=-F_{\Gamma}$, which is a contradiction. So we have $x_{1}=x_{2}=0$. This proves (2). The assertion (3) is proved in the same way.

Suppose that $I\left(\gamma_{1}\right)=I\left(\gamma_{2}\right)=1$. Then it follows from (3.4) and (4.1) that

$$
F_{\Gamma}\left(s_{1}+l_{1}, s_{2} \pm l_{2}\right)=F_{\Gamma}\left(s_{1}, s_{2}\right) .
$$

Hence the lattice $G(\Gamma)$ contains $\left(l_{1}, l_{2}\right)$ and $\left(l_{1},-l_{2}\right)$. Let $x_{1}$ and $x_{2}$ be real numbers such that

$$
\begin{equation*}
x_{1}\left(l_{1}, l_{2}\right)+x_{2}\left(l_{1},-l_{2}\right) \in G(\Gamma) . \tag{4.3}
\end{equation*}
$$

To establish (4) it is sufficient to show that $x_{1}$ and $x_{2}$ are integers. We may assume that $0 \leqq x_{i}<1$. It follows from (4.3) and Lemma 3.3 that $\left(x_{1}+x_{2}\right) l_{1}$ and $\left(x_{1}-x_{2}\right) l_{2}$ are periods of $\gamma_{1}$ and $\gamma_{2}$, respectively. So it follows that $x_{1}+x_{2}$ and $x_{1}-x_{2}$ are integers. Hence $\left(x_{1}, x_{2}\right)=(0,0)$ or $(1 / 2,1 / 2)$. We now consider the case $x_{1}=x_{2}=1 / 2$. By (4.3) we have $\left(l_{1}, 0\right) \in G(\Gamma)$, and so $F_{\Gamma}\left(s_{1}+l_{1}, s_{2}\right)=F_{\Gamma}\left(s_{1}, s_{2}\right)$. However it follows from $I\left(\gamma_{1}\right)=1$ that $F_{\Gamma}\left(s_{1}+l_{1}, s_{2}\right)=-F_{\Gamma}\left(s_{1}, s_{2}\right)$. Hence we have $F_{\Gamma}=-F_{\Gamma}$, which is a contradiction. This proves (4). Q.E.D.

In the rest of this section we construct a flat torus in $S^{3}$ which does not satisfy the antipodal symmetry. Let $\gamma: \boldsymbol{R} \rightarrow S^{2}$ be a periodic regular curve defined by

$$
\gamma(\theta)=\frac{x(\theta) e_{1}+y(\theta) e_{2}+e_{3}}{\sqrt{x(\theta)^{2}+y(\theta)^{2}+1}},
$$

where $x(\theta)=R(\theta) \sin \theta, y(\theta)=3 / 2-R(\theta) \cos \theta$ and $R(\theta)=1 / 2+\cos \theta$. The minimum period of $\gamma$ is equal to $2 \pi$ and $\gamma \mid[0,2 \pi]$ has exactly one self-intersection. Therefore $I(\gamma)=0$. We now introduce a function $\theta(s)$ by the following relation.

$$
s=\frac{1}{2} \int_{0}^{\theta(s)}\left\|\gamma^{\prime}\right\| \sqrt{1+k^{2}} d \theta
$$

where $k$ denotes the geodesic curvature of $\gamma$. Furthermore define a periodic regular curve $\gamma_{1}: \boldsymbol{R} \rightarrow S^{2}$ by $\gamma_{1}(s)=\gamma(\theta(s))$. Then it is not difficult to see the following lemma.

Lemma 4.2. Let $k_{1}$ be the geodesic curvature of $\gamma_{1}$, and let $l$ be a positive number with $\theta(l)=2 \pi$. Then
(1) $\hat{\gamma}_{1}(0)=\left(e_{3}, e_{1}\right)$,
(2) $\left\|\gamma_{1}^{\prime}\right\|^{2}\left(1+k_{1}^{2}\right)=4$,
(3) $k_{1}>0$,
(4) $l$ is the minimum period of $\gamma_{1}$ and $I\left(\gamma_{1}\right)=0$,
(5) $\left\langle\gamma_{1}(s), e_{2}\right\rangle>0$ unless $s / l$ is an integer.

Let $\Phi$ be an orientation reversing linear isometry of $\mathfrak{\mathfrak { u } ( 2 ) \text { such that } \Phi ( e _ { 1 } ) , ~ ( e ^ { \prime } )}$ $=e_{1}, \Phi\left(e_{2}\right)=-e_{2}$ and $\Phi\left(e_{3}\right)=e_{3}$. Define a periodic regular curve $\gamma_{2}: \boldsymbol{R} \rightarrow S^{2}$ by $\gamma_{2}(s)=\Phi\left(\gamma_{1}(s)\right)$. Since $k_{2}$, the geodesic curvature of $\gamma_{2}$, satisfies $k_{2}(s)=-k_{1}(s)$, it follows from Lemma 4.2 (1)-(3) that $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ is a periodic admissible pair. We set $E=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. Then

Lemma 4.3. $\quad F_{\Gamma}\left(s_{1}, s_{2}\right) \neq-E$ for all $\left(s_{1}, s_{2}\right) \in \boldsymbol{R}^{2}$.
Proof. Suppose that there exists $\left(t_{1}, t_{2}\right) \in \boldsymbol{R}^{2}$ such that $F_{\Gamma}\left(t_{1}, t_{2}\right)=-E$. Then it follows from (3.4) that $c_{1}\left(t_{1}\right)=-c_{2}\left(t_{2}\right)$, where $c_{i}$ denotes a curve in $S^{3}$ such that $p_{2}\left(c_{i}\right)=\hat{\gamma}_{i}$ and $c_{i}(0)=E$. Since $p_{2}(a)=p_{2}(-a)$, we obtain $\gamma_{1}\left(t_{1}\right)=\gamma_{2}\left(t_{2}\right)$. So it follows from Lemma 4.2 (5) that there exist integers $n_{1}$ and $n_{2}$ such that $t_{1}=n_{1} l$ and $t_{2}=n_{2} l$. By (4.1) and Lemma 4.2 (4) we obtain $c_{i}\left(t_{i}\right)=c_{i}\left(n_{i} l\right)=c_{i}(0)$ $=E$. Hence $F_{\Gamma}\left(t_{1}, t_{2}\right)=E$ which is a contradiction.
Q.E.D.

Since $F_{\Gamma}(0,0)=E$, the image of the immersion $f_{\Gamma}: M_{\Gamma} \rightarrow S^{3}$ contains $E$. On the other hand, Lemma 4.3 shows that $-E$ is not contained in the image of $f_{\Gamma}$. Therefore we obtain the following theorem.

Theorem 4.4. There exists a flat torus $M$ and an isometric immersion $f: M \rightarrow S^{3}$ such that the image $f(M)$ is not invariant under the antipodal map of $S^{3}$.

## 5. Asymptotic curves of embedded flat tori in $S^{3}$.

In this section we study asymptotic curves of flat tori isometrically embedded in $S^{3}$, and prove Theorem 1.1. We now recall the notion of asymptotic curves. Let $f: M \rightarrow S^{3}$ be an isometric immersion of a flat surface $M$ into $S^{3}$. A curve $c(s)$ in $M$ is said to be an asymptotic curve of the immersion $f$ if it satisfies the equation $h(\dot{c}, \dot{c})=0$, where $h$ denotes the second fundamental form of $f$. For each point of the flat surface $M$, there are exactly two asymptotic curves through the point.

Example. Let $\Gamma$ be an admissible pair, and let $f_{\Gamma}$ be the isometric immersion of the flat surface $M_{\Gamma}=\left(\boldsymbol{R}^{2}, g_{\Gamma}\right) / G(\Gamma)$ into $S^{3}$ defined by the relation $f_{\Gamma} \pi_{\Gamma}=F_{\Gamma}$, where $\pi_{\Gamma}$ denotes the canonical projection of $\boldsymbol{R}^{2}$ onto $M_{\Gamma}$. Consider two curves $a_{1}$ and $a_{2}$ in $M_{\Gamma}$ given by $a_{1}(s)=\pi_{\Gamma}(s, 0)$ and $a_{2}(s)=\pi_{\Gamma}(0, s)$. Since $F_{\Gamma}$ is a FAT, the curves $a_{1}$ and $a_{2}$ are unit speed asymptotic curve of $f_{\Gamma}$.

Theorem 5.1. Let $f: M \rightarrow S^{3}$ be an isometric immersion of a flat torus $M$ into $S^{3}$, and let $c: R \rightarrow M$ be a unit speed asymptotic curve of $f$. Then there exists a positive number $l$ such that $c(s+l)=c(s)$ and $c \mid[0, l]$ is a simple closed curve.

Proof. It follows from [2, Theorem A] that $c$ is periodic. So there exists a positive number $l$ which is the minimum period of $c$. Suppose that $c \mid[0, l]$ is not a simple closed curve. Then we may assume that there exists a positive number $l^{\prime}<l$ such that $c(0)=c\left(l^{\prime}\right)$. It follows from [3] that there exists a covering $T: \boldsymbol{R}^{2} \rightarrow M$ such that $f \circ T$ is a FAT. Since $c(s)$ is a unit speed asymptotic curve of $f$, we may assume that $c(s)=T(s, 0)$. Then $T(0,0)=$ $T\left(l^{\prime}, 0\right)$, and so there exists a covering transformation $\rho$ of $T$ such that $\rho(0,0)$ $=\left(l^{\prime}, 0\right)$. Since $f \circ T \circ \rho=f \circ T$, it follows from [2, Theorem 2.3] that $\rho\left(s_{1}, s_{2}\right)=$ $\left(s_{1}+l^{\prime}, s_{2}\right)$. Hence $c\left(s+l^{\prime}\right)=T(\rho(s, 0))=T(s, 0)=c(s)$. This contradicts the definition of $l$.
Q.E.D.

Let $f: M \rightarrow S^{3}$ be an isometric embedding of a flat torus $M$ into $S^{3}$, and let $\xi$ be a unit normal vector field along the embedding $f$. For each $t \in \boldsymbol{R}$, using the exponential map Exp: $T S^{3} \rightarrow S^{3}$, we define a map $f^{t}: M \rightarrow S^{3}$ by $f^{t}(x)=$ $\operatorname{Exp}(t \xi(x))$. Since $f^{0}=f$, there exists a positive number $\boldsymbol{\delta}$ such that the map $(x, t) \mapsto f^{t}(x)$, restricted on $M \times[0, \delta]$, is an embedding. For each simple closed curve $a:[0, l] \rightarrow M$, we denote by $\operatorname{lk}\left(f(a), f^{\grave{\delta}}(a)\right)$ the linking number of $f(a)$ and $f^{\grave{o}}(a)$.

Theorem 5.2. Let $a:[0, l] \rightarrow M$ be a simple closed curve. If $a$ is a unit speed asymptotic curve of the embedding $f$, then $1 \mathrm{k}\left(f(a), f^{\delta}(a)\right) \equiv 1(\bmod 2)$.

Proof. There exists a covering $T: \boldsymbol{R}^{2} \rightarrow M$ such that $f \circ T$ is a FAT. Since $a:[0, l] \rightarrow M$ is a unit speed asymptotic curve of $f$, we may assume that $a(s)$ $=T(s, 0)$ for $0 \leqq s \leqq l$. Then Theorem 5.1 implies that

$$
\begin{equation*}
T(s+l, 0)=T(s, 0) \quad \text { for all } s \in \boldsymbol{R} \tag{5.1}
\end{equation*}
$$

By [2, Theorem 4.3] there exists an admissible pair $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ such that $F_{\Gamma}=$ $A \circ f \circ T$ for some isometry $A$ of $S^{3}$, where $F_{\Gamma}$ denotes a FAT defined by (3.4). Let $c_{1}: \boldsymbol{R} \rightarrow S^{3}$ be a lift of $\hat{\gamma}_{1}$ with respect to $p_{2}$ such that $c_{1}(0)=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. Since $c_{1}(s)=F_{\Gamma}(s, 0)$, it follows from (5.1) that $c_{1}(s+l)=c_{1}(s)$ for all $s$. We set $b=$ $c_{1} \mid[0, l]$. Then $b=A(f(a))$, and so $b$ is a simple closed curve. Hence Lemma 2.3 implies

$$
\begin{equation*}
1 \mathrm{k}\left(b, E_{3}\right) \equiv 1 \quad(\bmod 2) \tag{5.2}
\end{equation*}
$$

We consider a family of simple closed curves $b^{t}:[0, l] \rightarrow S^{3}(0 \leqq t \leqq \delta)$ defined by $b^{t}=A\left(f^{t}(a)\right)$. Then

$$
\begin{equation*}
\operatorname{lk}\left(f(a), f^{t}(a)\right)= \pm \operatorname{lk}\left(b, b^{t}\right) \quad \text { for } 0<t \leqq \delta \tag{5.3}
\end{equation*}
$$

Define a map $F_{\Gamma}^{t}: \boldsymbol{R}^{2} \rightarrow S^{3}$ by $F_{\Gamma}^{t}=A \circ f^{t} \circ T$, and set $\eta\left(s_{1}, s_{2}\right)=d F_{\Gamma}^{t}\left(s_{1}, s_{2}\right) /\left.d t\right|_{t=0}$. Then it follows from the definition of $f^{t}$ that $\eta$ is a unit normal vector field along $F_{\Gamma}$ such that $F_{\Gamma}^{t}\left(s_{1}, s_{2}\right)=\operatorname{Exp}\left(\operatorname{tr}\left(s_{1}, s_{2}\right)\right)$. Since $b^{t}(s)=F_{\Gamma}^{t}(s, 0)$ for $0 \leqq s \leqq l$, we obtain

$$
\begin{equation*}
b^{t}(s)=\operatorname{Exp}(\operatorname{tg}(s, 0)) \quad \text { for } 0 \leqq s \leqq l . \tag{5.4}
\end{equation*}
$$

For each $\theta \in \boldsymbol{R}$, let $X_{\theta}(s)$ be a vector field along $c_{1}(s)$ defined by

$$
X_{\theta}(s)=(\cos \theta) \eta(s, 0)+(\sin \theta) E_{3}\left(c_{1}(s)\right)
$$

Note that $X_{\theta}(s+l)=X_{\theta}(s)$. For $0 \leqq t \leqq \delta$, define a closed curve $b_{\theta}^{t}:[0, l] \rightarrow S^{3}$ by $b_{\theta}^{t}(s)=\operatorname{Exp}\left(t X_{\theta}(s)\right)$. It follows from Lemmas 2.2 and 3.4 that $X_{\theta}(s)$ and $\dot{c}_{1}(s)$ are linearly independent, and so there exists a positive number $\varepsilon<\delta$ such that $b$ does not intersect $b_{\theta}^{t}$ for all $(\theta, t) \in \boldsymbol{R} \times(0, \varepsilon]$. Therefore we have

$$
1 \mathrm{k}\left(b, b_{0}^{\varepsilon}\right)=1 \mathrm{k}\left(b, b_{\pi / 2}^{\varepsilon}\right) .
$$

Since $b_{\pi / 2}^{t}(s)=\operatorname{Exp}\left(t E_{3}(b(s))\right)$, it follows from the above relation that $\operatorname{lk}\left(b, b_{0}^{\varepsilon}\right)=$ $1 \mathrm{k}\left(b, E_{3}\right)$. Furthermore it follows from (5.4) that $b_{0}^{\varepsilon}=b^{\varepsilon}$. So (5.3) implies

$$
\operatorname{lk}\left(f(a), f^{\delta}(a)\right)=\operatorname{lk}\left(f(a), f^{\mathrm{s}}(a)\right)= \pm 1 \mathrm{k}\left(b, E_{3}\right) .
$$

Hence (5.2) implies the assertion of Theorem 5.2.
Q.E.D.

Theorem 5.3. Let $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ be a periodic admissible pair. If the immersion $f_{\Gamma}: M_{\Gamma} \rightarrow S^{3}$ is an embedding, then $I\left(\gamma_{1}\right)=I\left(\gamma_{2}\right)=1$.

Proof. It is sufficient to show that the following three cases (1)-(3) are impossible.
(1) $I\left(\gamma_{1}\right)=0, I\left(\gamma_{2}\right)=0$,
(2) $I\left(\gamma_{1}\right)=1, I\left(\gamma_{2}\right)=0$,
(3) $I\left(\gamma_{1}\right)=0, I\left(\gamma_{2}\right)=1$.

We first assume (1). Let $l_{i}>0$ be the minimum period of $\gamma_{i}$. Then it follows from Theorem 4. 1 that the lattice $G(\Gamma)$ is generated by $\left(l_{1}, 0\right)$ and ( $0, l_{2}$ ). Let $\pi_{\Gamma}$ be the canonical projection of $\boldsymbol{R}^{2}$ onto $M_{\Gamma}=\boldsymbol{R}^{2} / G(\Gamma)$, and let $D$ be a disk of $M_{\Gamma}$ given by $D=\pi_{\Gamma}(\tilde{D})$, where $\tilde{D}$ is a domain of $\boldsymbol{R}^{2}$ such that

$$
\tilde{D}=\left(\frac{1}{3} l_{1}, \frac{2}{3} l_{1}\right) \times\left(\frac{1}{3} l_{2}, \frac{2}{3} l_{2}\right) .
$$

We consider a knot $K$ in $S^{3}$ defined by $K=f_{\Gamma}(\partial D)$. Since $K$ is unknotted, it follows that $\operatorname{Arf}(K)=0$, where $\operatorname{Arf}(K)$ denotes the $\operatorname{Arf}$ invariant of the knot $K$. We refer the reader to [1, Chapter 10] for the definition of $\operatorname{Arf}(K)$. Let $\xi$ be a unit normal vector field along the embedding $f_{\Gamma}$. For each $t \in \boldsymbol{R}$, we define a map $f_{\Gamma}^{t}: M_{\Gamma} \rightarrow S^{3}$ by $f_{\Gamma}^{t}(x)=\operatorname{Exp}(t \xi(x))$. Since $f_{\Gamma}^{0}=f_{\Gamma}$, there exists a positive number $\delta$ such that the map $(x, t) \mapsto f_{\Gamma}^{t}(x)$ is an embedding on $M_{\Gamma} \times$ $[0, \delta]$. We now compute $\operatorname{Arf}(K)$ using a Seifert surface of $K$. Let $V$ be a Seifert surface of $K$ defined by $V=f_{\Gamma}\left(M_{\Gamma}-D\right)$, and let $a_{1}$ and $a_{2}$ be simple closed curves in $M_{\Gamma}$ given by

$$
\begin{array}{ll}
a_{1}(s)=\pi_{\Gamma}(s, 0) & \text { for } 0 \leqq s \leqq l_{1}, \\
a_{2}(s)=\pi_{\Gamma}(0, s) & \text { for } 0 \leqq s \leqq l_{2} .
\end{array}
$$

Then $\left\{f_{\Gamma}\left(a_{1}\right), f_{\Gamma}\left(a_{2}\right)\right\}$ represents a canonical basis of the homology group $H_{1}(V)$. Hence it follows from [5] that

$$
\begin{equation*}
\operatorname{Arf}(K) \equiv v_{11} v_{22} \quad(\bmod 2) \tag{5.5}
\end{equation*}
$$

where $v_{i j}=\operatorname{lk}\left(f_{\Gamma}\left(a_{i}\right), f_{\Gamma}^{\dot{\delta}}\left(a_{j}\right)\right)$. Since $a_{i}$ is a unit speed asymptotic curve of $f_{\Gamma}$, it follows from Theorem 5.2 that $v_{i i}$ is odd. Therefore (5.5) implies $\operatorname{Arf}(K)=1$. This is a contradiction, and so (1) is impossible. By the same way we see that (2) and (3) are impossible.
Q.E.D.

Theorem 5.4. Let $f: M \rightarrow S^{3}$ be an isometric embedding of a flat torus $M$ into $S^{3}$. If $c: \boldsymbol{R} \rightarrow M$ is a unit speed asymptotic curve of $f$, then $f(c)$ is invariant under the antipodal map of $S^{3}$.

Proof. By Corollary 3.2 there exists a periodic admissible pair $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$
such that $f$ and $f_{\Gamma}$ are congruent. So, without loss of generality, we may assume that $M=M_{\Gamma}$ and $f=f_{\Gamma}$. Let $c_{i}: R \rightarrow S^{3}$ be a curve such that $p_{2}\left(c_{i}\right)=\hat{\gamma}_{i}$ and $c_{i}(0)=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. Since $f_{\Gamma}$ is an embedding, Theorem 5.3 implies $I\left(\gamma_{1}\right)=I\left(\gamma_{2}\right)$ $=1$. Hence it follows from (2.7) that

$$
\begin{equation*}
c_{i}\left(s+l_{i}\right)=-c_{i}(s) \quad(i=1,2) \tag{5.6}
\end{equation*}
$$

where $l_{i}$ denotes the minimum period of $\gamma_{i}$. Let $\tilde{c}$ be a lift of the curve $c$ with respect to the covering $\pi_{\Gamma}: \boldsymbol{R}^{2} \rightarrow M_{\Gamma}$. Then $\tilde{c}$ is a unit speed asymptotic curve of the immersion $F_{\Gamma}: \boldsymbol{R}^{2} \rightarrow S^{3}$. Since $F_{\Gamma}$ is a FAT, the curve $\tilde{c}$ satisfies

$$
\tilde{c}(s)=\left(u_{1} \pm s, u_{2}\right) \quad \text { or } \quad \tilde{c}(s)=\left(u_{1}, u_{2} \pm s\right),
$$

where $\left(u_{1}, u_{2}\right)=\tilde{c}(0)$. We first consider the case $\tilde{c}(s)=\left(u_{1} \pm s, u_{2}\right)$. Since $F_{\Gamma}=$ $f_{\Gamma} \circ \pi_{\Gamma}$, we have

$$
f_{\Gamma}(c(s))=F_{\Gamma}(\tilde{c}(s))=c_{1}\left(u_{1} \pm s\right) \cdot c_{2}\left(u_{2}\right)^{-1}
$$

Hence (5.6) implies $f_{\Gamma}\left(c\left(s+l_{1}\right)\right)=-f_{\Gamma}(c(s))$. Similarly we have $f_{\Gamma}\left(c\left(s+l_{2}\right)\right)=$ $-f_{\Gamma}(c(s))$ when $\tilde{c}(s)=\left(u_{1}, u_{2} \pm s\right)$. This completes the proof of Theorem 5.4.
Q.E.D.

As an immediate consequence of Theorem 5.4, we obtain Theorem 1.1.

## 6. Proof of Lemma 2.3.

In this section we prove Lemma 2.3. A curve $\gamma:[0,2 \pi] \rightarrow S^{2}$ is called a closed regular curve if there exists a regular curve $\tilde{\gamma}: \boldsymbol{R} \rightarrow S^{2}$ such that $\tilde{\gamma}(s+2 \pi)$ $=\tilde{\gamma}(s)$ and $\gamma=\tilde{\gamma} \mid[0,2 \pi]$. Let $\Omega^{0}$ be the set of all closed regular curves $\gamma:[0,2 \pi] \rightarrow S^{2}$ such that a lift of the curve $\hat{\gamma}:[0,2 \pi] \rightarrow U S^{2}$ with respect to the covering $p_{2}$ is a simple closed curve. For each $\gamma \in \Omega^{0}$, we set

$$
1 \mathrm{k}(\gamma)=1 \mathrm{k}\left(c, E_{3}\right),
$$

where $c$ denotes a lift of $\hat{\gamma}$ with respect to $p_{2}$. Note that $\operatorname{lk}(\gamma)$ does not depend on the choice of $c$. Then Lemma 2.3 is equivalent to the following assertion.

$$
\begin{equation*}
\operatorname{lk}(\gamma) \equiv 1 \quad(\bmod 2) \quad \text { for all } \gamma \in \Omega^{0} \tag{6.1}
\end{equation*}
$$

To establish (6.1) we need several lemmas.
Lemma 6.1. Let $\gamma:[0,2 \pi] \rightarrow S^{2}$ be a closed regular curve defined by $\gamma(s)=$ $(\cos 2 s) e_{1}+(\sin 2 s) e_{2}$. Then $\gamma \in \Omega^{0}$ and $\mathrm{lk}(\gamma)=1$.

Proof. Let $c:[0,2 \pi] \rightarrow S^{3}$ be a lift of $\hat{\gamma}$ with respect to $p_{2}$. Since $\gamma$ is a geodesic and $\left\|\gamma^{\prime}\right\|=2$, it follows from Lemma 2.2 that $\dot{c}=E_{2}(c)$. Hence $c$ is a unit speed geodesic in $S^{3}$. In particular, $c$ is a simple closed curve, and so
$\gamma \in \Omega^{0}$. We now compute $\mathrm{k}(\gamma)$. Let $\varphi^{t}$ be the 1 -parameter group of diffeomorphisms of $S^{3}$ generated by $E_{3}$. Since $\varphi^{t}(c)$ does not intersect $c$ for $0<t \leqq 1$, we obtain $1 \mathrm{k}(\gamma)=1 \mathrm{k}\left(c, E_{3}\right)=1 \mathrm{k}\left(c, \varphi^{1}(c)\right)$. We set

$$
\begin{aligned}
& v_{1}(s)=(\cos s) E_{3}(c(s))-(\sin s) E_{1}(c(s)), \\
& v_{2}(s)=(\sin s) E_{3}(c(s))+(\cos s) E_{1}(c(s)) .
\end{aligned}
$$

Let $X=S^{3}-\operatorname{Image}(c)$, and let $T:[0,2 \pi] \times[0,2 \pi] \rightarrow X$ be a map defined by

$$
T(\theta, s)=\operatorname{Exp}\left((\cos \theta) v_{1}(s)+(\sin \theta) v_{2}(s)\right)
$$

where Exp: $T S^{3} \rightarrow S^{3}$ denotes the exponential map. We consider simple closed curves $a_{1}(\theta)=T(\theta, 0)$ and $a_{2}(s)=T(2 \pi, s)$. Since $\varphi^{1}(c(s))=\operatorname{Exp}\left(E_{3}(c(s))\right)=T(s, s)$, it follows that $\left[\varphi^{1}(c)\right]=\left[a_{1}\right]+\left[a_{2}\right]$ in the homology group $H_{1}(X)$. Hence we obtain

$$
\operatorname{lk}(\gamma)=\operatorname{lk}\left(c, \varphi^{1}(c)\right)=\operatorname{lk}\left(c, a_{1}\right)+\operatorname{lk}\left(c, a_{2}\right)
$$

It is easy to see that $\operatorname{lk}\left(c, a_{1}\right)=1$. Since $v_{1}$ is parallel along the geodesic $c$, there exists a totally geodesic 2 -sphere $\Sigma$ in $S^{3}$ such that $c$ is contained in $\Sigma$ and $v_{1}$ is tangent to $\Sigma$ along $c$. Then the curve $a_{2}$ is contained in $\Sigma$, and so $1 \mathrm{k}\left(c, a_{2}\right)=0$.
Q.E.D.

Lemma 6.2. Let $\gamma_{t}:[0,2 \pi] \rightarrow S^{2}(0 \leqq t \leqq 1)$ be a smooth 1-parameter family of closed regular curves such that $\gamma_{t} \in \Omega^{0}$ for all $t$. Then $1 \mathrm{k}\left(\gamma_{0}\right)=1 \mathrm{k}\left(\gamma_{1}\right)$.

Proof. By the assumption there exists a smooth 1 -parameter family of simple closed curves $c_{t}:[0,2 \pi] \rightarrow S^{3}(0 \leqq t \leqq 1)$ such that $p_{2}\left(c_{t}\right)=\hat{\gamma}_{t}$. Then there exists a positive number $\delta$ such that $\operatorname{lk}\left(c_{t}, E_{3}\right)=\operatorname{lk}\left(c_{t}, \varphi^{\delta}\left(c_{t}\right)\right)$ for all $t$. Hence $1 \mathrm{k}\left(c_{t}, E_{3}\right)$ does not depend on $t$.
Q.E.D.

We define $\Omega *$ to be the set of all closed regular curves $\gamma:[0,2 \pi] \rightarrow S^{2}$ such that $\gamma$ is self-transversal and all of its self-intersections are double points.

Lemma 6.3. For each $\alpha \in \Omega^{0}$, there exists $\beta \in \Omega^{*} \cap \Omega^{0}$ such that $\operatorname{lk}(\alpha)=\operatorname{lk}(\beta)$.
Proof. Considering a sufficiently small deformation of $\alpha$, if necessary, we may assume that $\alpha(s) \neq \alpha(\pi)$ for $s \neq \pi$. We choose $q_{0} \in S^{2}$ which is not contained in the image of $\alpha$, and set

$$
\begin{aligned}
& A=\left\{x \in \mathfrak{u} \mathfrak{u}(2):\left\langle x, q_{0}\right\rangle=0\right\}, \\
& S^{+}=\left\{v \in S^{2}:\left\langle v, q_{0}\right\rangle>0\right\} .
\end{aligned}
$$

For each $v \in S^{+}$, define $\pi_{v}: \mathfrak{S u}(2) \rightarrow A$ to be the parallel projection in the direction of $v$. Let $f: A \rightarrow S^{2}-\left\{q_{0}\right\}$ be a diffeomorphism, and let $\gamma:[0,2 \pi] \rightarrow A$ be a closed regular curve given by $\gamma=f^{-1}(\alpha)$. Since $\gamma(s) \neq \gamma(\pi)$ for $s \neq \pi$, there exists a
simple closed regular curve $c:[0,2 \pi] \rightarrow \mathfrak{a n}(2)$ such that $\pi_{q_{0}}(c)=\gamma$. For each $v \in S^{+}$, define a curve $\alpha_{v}:[0,2 \pi] \rightarrow S^{2}$ by $\alpha_{v}=f\left(\pi_{v}(c)\right)$. Note that $\alpha_{q_{0}}=\alpha$. Since $\alpha \in \Omega^{0}$, there exists a neighborhood $W$ of $q_{0}$ in $S^{+}$such that $\alpha_{v} \in \Omega^{0}$ for all $v \in W$. The set of all $v \in S^{+}$with self-transversal $\pi_{v}(c)$ is dense in $S^{+}$. So there exists $q_{1} \in W$ such that $\alpha_{q_{1}}$ is self-transversal. Let $v: \boldsymbol{R} \rightarrow W$ be a smooth curve such that $v(0)=q_{0}$ and $v(1)=q_{1}$. Consider a smooth 1 -parameter family of closed regular curves $\alpha_{t}$ in $S^{2}$ defined by $\alpha_{t}=\alpha_{v(t)}$. Since $\alpha_{t} \in \Omega^{0}$ for $0 \leqq t \leqq 1$, it follows from Lemma 6.2 that $\operatorname{lk}(\alpha)=\operatorname{lk}\left(\alpha_{0}\right)=\operatorname{lk}\left(\alpha_{1}\right)$. Since $\alpha_{1}$ is self-transversal, a small deformation of $\alpha_{1}$ implies the existence of $\beta \in \Omega * \cap \Omega^{0}$ such that $\operatorname{lk}\left(\alpha_{1}\right)=\operatorname{lk}(\beta)$.
Q.E.D.

For each closed regular curve $\gamma:[0,2 \pi] \rightarrow S^{2}$, we denote by $[\hat{\gamma}]$ the element of the homology group $H_{1}\left(U S^{2}\right)$ represented by the closed curve $\hat{\gamma}:[0,2 \pi] \rightarrow U S^{2}$. By (2.7) it is easy to see the following lemma.

Lemma 6.4. Let $\gamma:[0,2 \pi] \rightarrow S^{2}$ be a closed regular curve such that $\hat{\gamma}$ is a simple closed curve. Then $\gamma \in \Omega^{0}$ if and only if $[\hat{\gamma}]=0$.

A closed regular curve $\gamma:[0,2 \pi] \rightarrow S^{2}$ is said to be self-contact free if $\hat{\gamma}$ is a simple closed curve. For $\alpha, \beta \in \Omega *$, we say that $\alpha$ and $\beta$ are $R 1$-related if there exists a smooth 1 -parameter family of self-contact free closed regular curves $\gamma_{t}:[0,2 \pi] \rightarrow S^{2}(0 \leqq t \leqq 1)$ such that $\alpha=\gamma_{0}$ and $\beta=\gamma_{1}$.

Lemma 6.5. Let $\alpha, \beta \in \Omega^{*}$ which are R1-related. If $\alpha \in \Omega^{0}$, then $\beta \in \Omega^{0}$ and $1 \mathrm{k}(\alpha)=1 \mathrm{k}(\beta)$.

Proof. Let $\gamma_{t}:[0,2 \pi] \rightarrow S^{2}(0 \leqq t \leqq 1)$ be a smooth 1-parameter family of self-contact free closed regular curves such that $\alpha=\gamma_{0}$ and $\beta=\gamma_{1}$. Since $\alpha \in \Omega^{0}$, it follows from (2.7) that $\left[\hat{\gamma}_{t}\right]=\left[\hat{\gamma}_{0}\right]=0$. So Lemma 6.4 implies that $\gamma_{t} \in \Omega^{0}$ for all $t$. Hence $\beta \in \Omega^{\circ}$, and it follows from Lemma 6.2 that $l k(\alpha)=l k(\beta)$. Q.E.D.

We now introduce another relation on $\Omega^{*}$. Let $B$ denote the set of all $\left(u_{1}, u_{2}\right) \in \boldsymbol{R}^{2}$ such that $\left|u_{i}\right| \leqq 1(i=1,2)$. Define $\Phi: B \rightarrow S^{2}$ by

$$
\Phi\left(u_{1}, u_{2}\right)=(\cos \rho) e_{3}+\frac{\sin \rho}{\rho}\left(u_{1} e_{1}+u_{2} e_{2}\right)
$$

where $\rho=\sqrt{u_{1}^{2}+u_{2}^{2}}$. We consider a closed regular curve $\gamma:[0,2 \pi] \rightarrow S^{2}$ which satisfies

$$
\begin{cases}\gamma(s)=\Phi\left(s-1,-(s-1)^{2}\right) & \text { if } 0 \leqq s \leqq 2  \tag{6.2}\\ \gamma(s)=\Phi(s-4,0) & \text { if } 3 \leqq s \leqq 5 \\ \gamma(s) \notin \Phi(B) & \text { otherwise }\end{cases}
$$

Let $h: \boldsymbol{R} \rightarrow[0,1 / 9]$ be a smooth function such that $h(x)=0$ for $|x| \geqq 2 / 3$ and
$h(x)=1 / 9$ for $|x| \leqq 1 / 3$. Define a smooth 1-parameter family of closed regular curves $\gamma_{t}:[0,2 \pi] \rightarrow S^{2}(-1 \leqq t \leqq 1)$ by setting

$$
\gamma_{t}(s)= \begin{cases}\Phi\left(s-1,-(s-1)^{2}+h(s-1) t\right) & \text { if } 0 \leqq s \leqq 2  \tag{6.3}\\ \gamma(s) & \text { otherwise }\end{cases}
$$

Since $\left[\hat{\gamma}_{1}\right]=\left[\hat{\gamma}_{-1}\right]$, it follows from Lemma 6.4 that

$$
\begin{equation*}
\gamma_{1} \in \Omega^{*} \cap \Omega^{0} \quad \text { if and only if } \gamma_{-1} \in \Omega^{*} \cap \Omega^{0} . \tag{6.4}
\end{equation*}
$$

For $\alpha, \beta \in \Omega^{*}$, we say that $\alpha$ and $\beta$ are $R 2$-related if there exists a closed regular curve $\gamma:[0,2 \pi] \rightarrow S^{2}$ with the condition (6.2) and the family $\gamma_{t}$ given by (6.3) satisfies $\left(\gamma_{1}, \gamma_{-1}\right)=(\alpha, \beta)$ or $(\beta, \alpha)$.

Lemma 6.6. Let $\alpha, \beta \in \Omega^{*}$ which are R2-related. If $\alpha \in \Omega^{0}$, then $\beta \in \Omega^{0}$ and $1 \mathrm{k}(\alpha) \equiv \operatorname{lk}(\beta)(\bmod 2)$.

Proof. By (6.4) we may assume that there exists a closed regular curve $\gamma:[0,2 \pi] \rightarrow S^{2}$ with the condition (6.2) and the family $\gamma_{t}(-1 \leqq t \leqq 1)$ defined by (6.3) satisfies $\gamma_{1}=\alpha$ and $\gamma_{-1}=\beta$. Since $\gamma_{1} \in \Omega^{*} \cap \Omega^{0}$, it follows from the definition of $\gamma_{t}$ that

$$
\begin{equation*}
\gamma_{t} \in \Omega^{*} \cap \Omega^{0} \quad \text { for } t \neq 0 \tag{6.5}
\end{equation*}
$$

To establish Lemma 6.6 it is sufficient to show the following assertion.

$$
\begin{equation*}
1 \mathrm{k}\left(\gamma_{1}\right)-1 \mathrm{k}\left(\gamma_{-1}\right)=0 \text { or }-2 . \tag{6.6}
\end{equation*}
$$

If $\gamma_{0} \in \Omega^{0}$, then it follows from (6.5) and Lemma 6.2 that $\operatorname{lk}\left(\gamma_{1}\right)=1 \mathrm{k}\left(\gamma_{-1}\right)$. So we may assume $\gamma_{0} \notin \Omega^{0}$. Since $\hat{\gamma}_{0}(1)=\left(e_{3}, e_{1}\right) \in U S^{2}$, there exists a smooth 1-parameter family of closed curves $c_{t}:[0,2 \pi] \rightarrow S^{3}(-1 \leqq t \leqq 1)$ such that $p_{2}\left(c_{t}\right)=\hat{\gamma}_{t}$ and $c_{0}(1)$ $=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. Since $\hat{\gamma}_{0}(1)=\hat{\gamma}_{0}(4)$, it follows from the assumption $\gamma_{0} \notin \Omega^{0}$ that

$$
c_{0}(1)=c_{0}(4)=\left[\begin{array}{ll}
1 & 0  \tag{6.7}\\
0 & 1
\end{array}\right] .
$$

Let $\tilde{B}$ denote the set of all $(x, y, z) \in \boldsymbol{R}^{3}$ such that $|x| \leqq 1 / 2,|y| \leqq 1 / 2$ and $|z|<$ $\pi / 2$. Define $\tilde{\Phi}: \tilde{B} \rightarrow S^{3}$ by

$$
\tilde{\Phi}(x, y, z)=\exp \left(x e_{1}+y e_{2}\right) \exp \left(z e_{3}\right) .
$$

Then $\tilde{\Phi}$ carries $\tilde{B}$ diffeomorphically onto $\tilde{\Phi}(\tilde{B})$, and satisfies

$$
\begin{equation*}
p(\tilde{\Phi}(x, y, z))=\Phi(2 y,-2 x) \tag{6.8}
\end{equation*}
$$

where $p: S^{3} \rightarrow S^{2}$ denotes the Hopf fibration given in Section 2. For $i=1,2$, we define $V_{i}$ to be the vector field on $\Phi(B)$ such that $V_{i}(\Phi(0,0))=\partial \Phi(0,0) / \partial u_{i}$ and $V_{i}$ is parallel along every geodesic through the point $\Phi(0,0)$. Then it follows
from Lemma 2. 1 that

$$
\begin{equation*}
p_{2}(\widetilde{\Phi}(x, y, z))=(\cos 2 z) V_{1}(m)+(\sin 2 z) V_{2}(m), \tag{6.9}
\end{equation*}
$$

where $m=p(\widetilde{\Phi}(x, y, z))$. Let $\theta(s, t)$ be a smooth function defined on $[0,2] \times$ $[-1,1]$ such that

$$
\begin{equation*}
\hat{r}_{t}(s)=(\cos \theta(s, t)) V_{1}+(\sin \theta(s, t)) V_{2}, \tag{6.10}
\end{equation*}
$$

and $\theta(1,0)=0$. It is easy to see that $|\theta(t, s)|<\pi$. For $-1 \leqq t \leqq 1$, define $\tilde{c}_{t}$ : $[0,2] \rightarrow \tilde{B}$ by $\tilde{c}_{t}=\left(x_{t}, y_{t}, z_{t}\right)$, where

$$
\begin{aligned}
& x_{t}(s)=\left\{(s-1)^{2}-h(s-1) t\right\} / 2, \\
& y_{t}(s)=(s-1) / 2, \\
& z_{t}(s)=\theta(s, t) / 2 .
\end{aligned}
$$

Then it follows from (6.7)-(6.10) that

$$
c_{t}(s)= \begin{cases}\tilde{\Phi}\left(\tilde{c}_{t}(s)\right) & \text { if } 0 \leqq s \leqq 2,  \tag{6.11}\\ \tilde{\Phi}(0,(s-4) / 2,0) & \text { if } 3 \leqq s \leqq 5, \\ c_{0}(s) & \text { otherwise } .\end{cases}
$$

Note that $s=1 \pm 1 / 3$ are the only zeros of the function $x_{1}(s)$ and that

$$
\begin{equation*}
z_{1}(2 / 3)>0, \quad z_{1}(4 / 3)<0 . \tag{6.12}
\end{equation*}
$$

Let $\tilde{a}:[0,2] \rightarrow \tilde{B}$ be the straight line from $\tilde{c}_{0}(0)$ to $\tilde{c}_{0}(2)$, and let $\tilde{b}:[0,2] \rightarrow \tilde{B}$ be a piecewise smooth curve given by

$$
\delta(s)= \begin{cases}(-s,-1 / 2,0) & \text { if } 0 \leqq s \leqq 1 / 2, \\ (-1 / 2, s-1,0) & \text { if } 1 / 2 \leqq s \leqq 3 / 2, \\ (s-2,1 / 2,0) & \text { if } 3 / 2 \leqq s \leqq 2 .\end{cases}
$$

For $t= \pm 1$, we define closed curves $a_{t}:[0,4] \rightarrow S^{3}$ by

$$
a_{t}(s)= \begin{cases}\tilde{\Phi}\left(\tilde{c}_{t}(s)\right) & \text { if } 0 \leqq s \leqq 2, \\ \tilde{\Phi}(\tilde{a}(4-s)) & \text { if } 2 \leqq s \leqq 4 .\end{cases}
$$

Furthermore define closed curves $b:[0,3] \rightarrow S^{3}$ and $c:[0,2 \pi] \rightarrow S^{3}$ by

$$
b(s)= \begin{cases}\tilde{\Phi}(0, s-1 / 2,0) & \text { if } 0 \leqq s \leqq 1, \\ \tilde{\Phi}(\tilde{b}(3-s)) & \text { if } 1 \leqq s \leqq 3,\end{cases}
$$

$$
c(s)= \begin{cases}\tilde{\Phi}(\tilde{a}(s)) & \text { if } 0 \leqq s \leqq 2, \\ \tilde{\Phi}(\tilde{b}(s-3)) & \text { if } 3 \leqq s \leqq 5, \\ c_{0}(s) & \text { otherwise } .\end{cases}
$$

We now compute $\operatorname{lk}\left(\gamma_{1}\right)$ and $\operatorname{lk}\left(\gamma_{-1}\right)$. Let $\delta$ be a positive number such that $\varphi^{t}\left(c_{1}\right)$ (resp. $\varphi^{t}\left(c_{-1}\right)$ ) does not intersect $c_{1}$ (resp. $c_{-1}$ ) for all $0<t \leqq \delta$. Define $D_{1}$ to be the union of the images of the curves $a_{1}, b$ and $c$. By the definition of $\tilde{\Phi}$, we see that $\varphi^{t}(\tilde{\Phi}(x, y, z))=\tilde{\Phi}(x, y, z+t)$. So we may assume that $D_{1}$ does not intersect $D_{1}^{\delta}$, where $D_{1}^{\delta}=\varphi^{\delta}\left(D_{1}\right)$. Then it follows from (6.11) that $\left[c_{1}^{\delta}\right]=\left[a_{1}^{\delta}\right]+$ $\left[b^{\delta}\right]+\left[c^{\delta}\right]$ in the homology group $H_{1}\left(S^{3}-D_{1}\right)$, where $c_{1}^{\delta}=\varphi^{\delta}\left(c_{1}\right), a_{1}^{\delta}=\varphi^{\delta}\left(a_{1}\right), b^{\delta}=$ $\varphi^{\delta}(b)$ and $c^{\delta}=\varphi^{\delta}(c)$. Hence we obtain

$$
\operatorname{lk}\left(c_{1}, c_{1}^{\delta}\right)=\operatorname{lk}\left(c_{1}, a_{1}^{\delta}\right)+\operatorname{lk}\left(c_{1}, b^{\delta}\right)+\operatorname{lk}\left(c_{1}, c^{\delta}\right) .
$$

Since $\left[c_{1}\right]=\left[a_{1}\right]+[b]+[c]$ in $H_{1}\left(S^{3}-D_{1}^{\delta}\right)$, it follows that

$$
\begin{aligned}
\operatorname{lk}\left(c_{1}, c_{1}^{\delta}\right)= & \operatorname{lk}\left(a_{1}, a_{1}^{\delta}\right)+1 \mathrm{k}\left(b, a_{1}^{\delta}\right)+\operatorname{lk}\left(c, a_{1}^{\delta}\right) \\
& +\operatorname{lk}\left(a_{1}, b^{\delta}\right)+1 \mathrm{k}\left(b, b^{\delta}\right)+\operatorname{lk}\left(c, b^{\delta}\right) \\
& +\operatorname{lk}\left(a_{1}, c^{\delta}\right)+\operatorname{lk}\left(b, c^{\delta}\right)+\operatorname{lk}\left(c, c^{\delta}\right) .
\end{aligned}
$$

It is easy to see that $\operatorname{lk}\left(a_{1}, b^{\delta}\right)=1 \mathrm{k}\left(b, a_{1}^{\delta}\right)=1 \mathrm{k}\left(a_{1}, b\right)$ and the other terms on the right hand side are equal to zero, except for $\mathrm{k}\left(c, c^{\delta}\right)$. Hence

$$
1 \mathrm{k}\left(\gamma_{1}\right)=1 \mathrm{k}\left(c, c^{\delta}\right)+21 \mathrm{k}\left(a_{1}, b\right) .
$$

By the same way we have

$$
1 \mathrm{k}\left(\gamma_{-1}\right)=1 \mathrm{k}\left(c, c^{\delta}\right)+21 \mathrm{k}\left(a_{-1}, b\right) .
$$

Since $\tilde{\Phi}$ is orientation preserving, it follows from (6.12) that $\operatorname{lk}\left(a_{1}, b\right)=\operatorname{lk}\left(\tilde{\Phi}^{-1}\left(a_{1}\right)\right.$, $\left.\tilde{\Phi}^{-1}(b)\right)=-1$. On the other hand, $1 \mathrm{k}\left(a_{-1}, b\right)=0$ since $x_{-1}(s)>0$. This implies (6.6).
Q.E.D.

For $\alpha, \beta \in \Omega^{*}$, we write $\alpha \sim \beta$ if there exists a sequence $\alpha_{0}, \alpha_{1}, \cdots, \alpha_{n}$ in $\Omega^{*}$ such that $\alpha=\alpha_{0}$ and $\beta=\alpha_{n}$ and that $\alpha_{i-1}$ and $\alpha_{i}$ are R1 (or R2)-related for $1 \leqq i \leqq n$.

Lemma 6.7. Let $\alpha, \beta \in \Omega^{*}$. If $[\hat{\alpha}]=[\hat{\beta}]=0$, then $\alpha \sim \beta$.
Proof. For each $\gamma \in \Omega^{*}$, we denote by $\# \gamma$ the number of double points of $\gamma$. We choose $\gamma_{0}, \gamma_{1} \in \Omega^{*}$ such that $\# \gamma_{0}=0$ and $\# \gamma_{1}=1$. Then it follows that $\alpha \sim \gamma_{0}$ or $\alpha \sim \gamma_{1}$. If $\alpha \sim \gamma_{0}$, we see that $[\hat{\alpha}]=\left[\hat{\gamma}_{0}\right]=1$. So the assumption implies that $\alpha \sim \gamma_{1}$. Similarly we obtain $\beta \sim \gamma_{1}$.
Q.E.D.

We now prove (6.1). By Lemma 6.3 we may assume that $\gamma \in \Omega^{*} \cap \Omega^{0}$. It
follows from Lemmas 6.1 and 6.3 that there exists $\beta \in \Omega * \cap \Omega^{0}$ such that $1 \mathrm{k}(\beta)$ $=1$. Since $[\hat{\gamma}]=[\hat{\beta}]=0$, it follows from Lemma 6.7 that $\gamma \sim \beta$. By Lemmas 6.5 and 6.6 we obtain $1 \mathrm{k}(\gamma) \equiv \mathrm{lk}(\beta)(\bmod 2)$. Hence $\mathrm{lk}(\gamma) \equiv 1(\bmod 2)$.

## 7. Gauss maps.

As explained in Section 3, the author [2] established a method for constructing all the flat tori in $S^{3}$. Recently Weiner [8] obtained another method which is based on the study of the Gauss maps of flat tori in $S^{3}$. In this section, for each admissible pair $\Gamma$, we compute the Gauss map of the immersion $F_{\Gamma}: \boldsymbol{R}^{2} \rightarrow S^{3}$. The result of this computation will help us to understand the relation between the two methods.

First, we explain the Gauss maps of immersed surfaces in $S^{3}$. Let $F: \boldsymbol{R}^{2}$ $\rightarrow S^{3}$ be an immersion, and let $\eta$ be a unit normal vector field along $F$ given by

$$
\eta=\partial_{1} F \times \partial_{2} F /\left\|\partial_{1} F \times \partial_{2} F\right\|,
$$

where $\times$ denotes the usual vector product on each tangent space of $S^{3}$ defined by using the metric and the orientation of $S^{3}$. Since $S^{3}=S U(2)$, we obtain two maps $\alpha, \beta: \boldsymbol{R}^{2} \rightarrow S^{2} \subset \mathfrak{G} \mathfrak{u}(2)$ by setting $\alpha=\left(R_{\boldsymbol{F}}^{-1}\right) * \eta$ and $\beta=\left(L_{\bar{F}}^{-1}\right) * \eta$. We call $\alpha$ (resp. $\beta$ ) the right (resp. left) Gauss map of the immersion $F$. We now consider another Gauss map. Let $\boldsymbol{H}$ denote the set of all quaternions

$$
x=x_{1}+x_{2} i+x_{3} j+x_{4} k .
$$

Then $\boldsymbol{H}$ can be viewed as a 4 -dimensional oriented Euclidean vector space by setting $\{1, i, j, k\}$ as a positive orthonormal basis of $\boldsymbol{H}$. Identifying each complex number $x_{1}+x_{2} \sqrt{-1}$ with the quaternion $x_{1}+x_{2} i$, we define a map $\varphi: S^{3} \rightarrow \boldsymbol{H}$ by

$$
\varphi\left(\left[\begin{array}{rr}
g_{1} & g_{2} \\
-\bar{g}_{2} & \bar{g}_{1}
\end{array}\right]\right)=g_{1}+g_{2} j .
$$

The $\operatorname{map} \varphi$ is an isometric embedding and it satisfies

$$
\begin{gather*}
\|\varphi(a)\|=1 \quad \text { for all } a \in S^{3},  \tag{7.1}\\
\varphi(a b)=\varphi(a) \varphi(b) \quad \text { for all } a, b \in S^{3} . \tag{7.2}
\end{gather*}
$$

Using the map $\varphi$, we identify $S^{3}$ with the set of all quaternions of unit norm. Then, as in [8], the immersion $F: \boldsymbol{R}^{2} \rightarrow S^{3} \subset \boldsymbol{H}$ induces a map $G: \boldsymbol{R}^{2} \rightarrow G_{2,4}$ which is called the Gauss map of $F$. Here $G_{2,4}$ is the Grassmannian of oriented 2dimensional subspaces of $\boldsymbol{H}$. The Grassmannian $G_{2,4}$ can be viewed as the set of all unit decomposable 2-vectors in $\wedge^{2} \boldsymbol{H}$, and the Gauss map $G$ is given by

$$
\begin{equation*}
G=\partial_{1} \tilde{F} \wedge \partial_{2} \tilde{F} /\left\|\partial_{1} \tilde{F} \wedge \partial_{2} \tilde{F}\right\|, \tag{7.3}
\end{equation*}
$$

where $\tilde{F}=\varphi \cdot F$.
We now study the relation between the maps $\alpha, \beta$ and $G$. Let $*: \wedge^{2} \boldsymbol{H} \rightarrow$ $\wedge^{2} \boldsymbol{H}$ be the Hodge star, and let $E_{+}$(resp. $E_{-}$) be the +1 (resp. -1 ) eigenspace of $*$. Then we have the orthogonal decomposition $\wedge^{2} \boldsymbol{H}=E_{+} \oplus E_{-}$. The projections $p_{ \pm}: \wedge^{2} \boldsymbol{H} \rightarrow E_{ \pm}$are given by $p_{ \pm}(v)=(v \pm * v) / 2$ for all $v \in \wedge^{2} \boldsymbol{H}$.

Lemma 7.1. Let $x$ be a quaternion of unit norm, and let $R_{x}$ and $L_{x}$ denote linear transformations of $\boldsymbol{H}$ defined by $R_{x}(y)=y x$ and $L_{x}(y)=x y$. Then
(1) $p_{+} \circ\left(\wedge^{2} R_{x}\right)=p_{+}$,
(2) $p_{-} \circ\left(\wedge^{2} L_{x}\right)=p_{-}$.

Proof. Since $R_{x}$ is an orientation preserving linear isometry, the operator $\wedge^{2} R_{x}$ commutes with the Hodge star $*$. Hence we obtain $p_{+} \circ\left(\wedge^{2} R_{x}\right)=\left(\wedge^{2} R_{x}\right)$ $\circ p_{+}$. On the other hand, a straightforward calculation shows that

$$
\begin{aligned}
& x \wedge i x+j x \wedge k x=1 \wedge i+j \wedge k, \\
& x \wedge j x+k x \wedge i x=1 \wedge j+k \wedge i \\
& x \wedge k x+i x \wedge j x=1 \wedge k+i \wedge j
\end{aligned}
$$

This implies $\left(\wedge^{2} R_{x}\right) \circ p_{+}=p_{+}$, and so we obtain (1). The assertion (2) is proved in the same way.
Q.E.D.

Let $\varphi_{ \pm}: \mathfrak{s u}(2) \rightarrow E_{ \pm}$be linear maps defined by the following relations.

$$
\begin{aligned}
& \varphi_{ \pm}\left(e_{1}\right)=\sqrt{2} p_{ \pm}\left(\varphi_{*} e_{2} \wedge \varphi_{*} e_{3}\right), \\
& \varphi_{ \pm}\left(e_{2}\right)=\sqrt{2} p_{ \pm}\left(\varphi_{*} e_{3} \wedge \varphi_{*} e_{1}\right), \\
& \varphi_{ \pm}\left(e_{3}\right)=\sqrt{2} p_{ \pm}\left(\varphi_{*} e_{1} \wedge \varphi_{*} e_{2}\right),
\end{aligned}
$$

where $\left\{e_{1}, e_{2}, e_{3}\right\}$ is a positive orthonormal basis of $\mathfrak{h u}(2)$ given in Section 2. It is easy to see that $\varphi_{+}$and $\varphi_{-}$are linear isometries. We set $G_{ \pm}=p_{ \pm} \circ G$. Then we obtain

Lemma 7.2.

$$
G_{+}=\frac{1}{\sqrt{2}} \varphi_{+}(\alpha), \quad G_{-}=\frac{1}{\sqrt{2}} \varphi_{-}(\beta) .
$$

Proof. For $i=1,2$, define $a_{i}: \boldsymbol{R}^{2} \rightarrow \mathfrak{a} \mathfrak{u}(2)$ by $a_{i}=\left(R_{F}{ }^{-1}\right)_{*} \partial_{i} F$. Then it follows from (7.2) that $\partial_{i} \tilde{F}=\varphi_{*}\left(R_{F}\right)_{*} a_{i}=R_{\tilde{F}}\left(\varphi_{*} a_{i}\right)$, and so

$$
\partial_{1} \tilde{F} \wedge \partial_{2} \tilde{F}=\left(\wedge^{2} R_{\tilde{F}}\right)\left(\varphi_{*} a_{1} \wedge \varphi_{*} a_{2}\right)
$$

By (7.1) the immersion $\tilde{F}: \boldsymbol{R}^{2} \rightarrow \boldsymbol{H}$ satisfies $\left\|\tilde{F}\left(s_{1}, s_{2}\right)\right\|=1$. Therefore Lemma 7.1 implies

$$
\begin{equation*}
p_{+}\left(\partial_{1} \tilde{F} \wedge \partial_{2} \tilde{F}\right)=p_{+}\left(\varphi_{*} a_{1} \wedge \varphi_{*} a_{2}\right) . \tag{7.4}
\end{equation*}
$$

On the other hand, it follows from the definition of $\varphi_{+}$that

$$
\begin{equation*}
\varphi_{+}\left(a_{1} \times a_{2}\right)=\sqrt{2} p_{+}\left(\varphi_{*} a_{1} \wedge \varphi_{*} a_{2}\right) . \tag{7.5}
\end{equation*}
$$

Since $\alpha=a_{1} \times a_{2} /\left\|a_{1} \times a_{2}\right\|$ and $\left\|\partial_{1} \tilde{F} \wedge \partial_{2} \tilde{F}\right\|=\left\|a_{1} \times a_{2}\right\|$, it follows from (7.3)-(7.5) that $G_{+}=(1 / \sqrt{2}) \varphi_{+}(\alpha)$. By the same way we obtain $G_{-}=(1 / \sqrt{2}) \varphi_{-}(\beta)$. Q.E.D.

Note that in [8] the maps $G_{+}$and $G_{-}$are denoted by $G_{1}$ and $G_{2}$, respectively. We now consider an admissible pair $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$, and compute the Gauss map of the immersion $F_{\Gamma}$.

Lemma 7.3. Let $\alpha$ (resp. $\beta$ ) be the right (resp. left) Gauss map of the immersion $F_{\Gamma}$. Then
(1) $\alpha\left(s_{1}, s_{2}\right)=\gamma_{1}^{\prime}\left(s_{1}\right) /\left\|\gamma_{1}^{\prime}\left(s_{1}\right)\right\|$,
(2) $\beta\left(s_{1}, s_{2}\right)=\gamma_{2}^{\prime}\left(s_{2}\right) /\left\|\gamma_{2}^{\prime}\left(s_{2}\right)\right\|$.

Proof. For simplicity, we set $F=F_{\Gamma}$. By (3.4) we obtain

$$
\begin{equation*}
F\left(s_{1}, s_{2}\right)=c_{1}\left(s_{1}\right) \cdot c_{2}\left(s_{2}\right)^{-1}, \tag{7.6}
\end{equation*}
$$

where $c_{i}$ denotes a curve in $S^{3}$ such that $p_{2}\left(c_{i}\right)=\hat{\gamma}_{i}$ and $c_{i}(0)=\left[\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right]$. Define $v_{i}: \boldsymbol{R} \rightarrow \mathfrak{p u}(2)$ by setting $v_{i}(s)=\left(L_{c_{i}(s)}^{-1}\right) * \dot{c}_{i}(s)$. Then it follows from (7.6) that

$$
\left(R_{F}^{-1}\right) * \partial_{1} F=\operatorname{Ad}\left(c_{1}\left(s_{1}\right)\right) v_{1}\left(s_{1}\right), \quad\left(R_{F}^{-1}\right) * \partial_{2} F=-\operatorname{Ad}\left(c_{1}\left(s_{1}\right)\right) v_{2}\left(s_{2}\right) .
$$

Hence

$$
\begin{equation*}
\alpha\left(s_{1}, s_{2}\right)=\frac{-\operatorname{Ad}\left(c_{1}\left(s_{1}\right)\right)\left(v_{1}\left(s_{1}\right) \times v_{2}\left(s_{2}\right)\right)}{\left\|v_{1}\left(s_{1}\right) \times v_{2}\left(s_{2}\right)\right\|} \tag{7.7}
\end{equation*}
$$

By Lemma 2.2 we see that $v_{i}=\left\|\gamma_{i}^{\prime}\right\|\left(e_{2}+k_{i} e_{3}\right) / 2$, where $k_{i}$ denotes the geodesic curvature of $\gamma_{i}$. This shows

$$
\begin{equation*}
v_{1}\left(s_{1}\right) \times v_{2}\left(s_{2}\right)=\frac{1}{4}\left\|\gamma_{1}^{\prime}\left(s_{1}\right)\right\|\left\|\gamma_{2}^{\prime}\left(s_{2}\right)\right\|\left(k_{2}\left(s_{2}\right)-k_{1}\left(s_{1}\right)\right) e_{1} \tag{7.8}
\end{equation*}
$$

Since $k_{1}\left(s_{1}\right)>k_{2}\left(s_{2}\right)$, it follows from (7.7) and (7.8) that $\alpha\left(s_{1}, s_{2}\right)=\operatorname{Ad}\left(c_{1}\left(s_{1}\right)\right) e_{1}$. By (2.1) and (2.2) we also have $\operatorname{Ad}\left(c_{1}\left(s_{1}\right)\right) e_{1}=\gamma_{1}^{\prime}\left(s_{1}\right) /\left\|\gamma_{1}^{\prime}\left(s_{1}\right)\right\|$. This implies (1). The assertion (2) is proved in the same way.
Q.E.D.

Combining Lemmas 7.2 and 7.3, we obtain the following theorem.
Theorem 7.4. Let $\Gamma=\left(\gamma_{1}, \gamma_{2}\right)$ be an admissible pair, and let $G$ be the Gauss map of the immersion $F_{\Gamma}: \boldsymbol{R}^{2} \rightarrow S^{3}$. Then
(1) $G_{+}\left(s_{1}, s_{2}\right)=\frac{1}{\sqrt{2}} \varphi_{+}\left(\gamma_{1}^{\prime}\left(s_{1}\right) /\left\|\gamma_{1}^{\prime}\left(s_{1}\right)\right\|\right)$,
(2)

$$
G_{-}\left(s_{1}, s_{2}\right)=\frac{1}{\sqrt{2}} \varphi_{-}\left(\gamma_{2}^{\prime}\left(s_{2}\right) /\left\|\gamma_{2}^{\prime}\left(s_{2}\right)\right\|\right) .
$$
