# On the topology of projective subspaces in complex Fermat varieties 

By Alex Degtyarev and Ichiro Shimada

(Received Sep. 22, 2014)

#### Abstract

Let $X$ be the complex Fermat variety of dimension $n=2 d$ and degree $m>2$. We investigate the submodule of the middle homology group of $X$ with integer coefficients generated by the classes of standard $d$-dimensional subspaces contained in $X$, and give an algebraic (or rather combinatorial) criterion for the primitivity of this submodule.

## 1. Introduction.

Unless specified otherwise, all (co-)homology groups are with coefficients in $\mathbb{Z}$.
Let $X$ be the complex Fermat variety

$$
z_{0}^{m}+\cdots+z_{n+1}^{m}=0
$$

of dimension $n$ and degree $m>2$ in a projective space $\mathbb{P}^{n+1}$ with homogeneous coordinates $\left(z_{0}: \cdots: z_{n+1}\right)$. Suppose that $n=2 d$ is even. Let $\mathcal{J}$ be the set of all unordered partitions of the index set $\overline{n+1}:=\{0,1, \ldots, n+1\}$ into unordered pairs, i.e., lists

$$
J:=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right]
$$

of pairs of indices such that

$$
\begin{equation*}
\left\{j_{0}, k_{0}, \ldots, j_{d}, k_{d}\right\}=\overline{n+1}, \quad j_{i}<k_{i}(i=0, \ldots, d), \quad j_{0}<\cdots<j_{d} \tag{1.1}
\end{equation*}
$$

and let $\mathcal{B}$ be the set of $(d+1)$-tuples $\beta=\left(\beta_{0}, \ldots, \beta_{d}\right)$ of complex numbers $\beta_{i}$ such that $\beta_{i}^{m}=-1$. (Note that we always have $j_{0}=0$.) For $J \in \mathcal{J}$ and $\beta \in \mathcal{B}$, we define the standard $d$-space $L_{J, \beta}$ to be the projective subspace of $\mathbb{P}^{n+1}$ defined by the equations

$$
\begin{equation*}
z_{k_{i}}=\beta_{i} z_{j_{i}} \quad(i=0, \ldots, d) \tag{1.2}
\end{equation*}
$$

The number of these spaces equals $(2 d+1)!!m^{d+1}$, where $(2 d+1)!!$ is the product of all odd numbers from 1 to $(2 d+1)$. Each standard $d$-space $L_{J, \beta}$ is contained in $X$, and hence we have its class [ $L_{J, \beta}$ ] in the middle homology group $H_{n}(X)$ of $X$. Let $\mathcal{L}(X)$ denote the $\mathbb{Z}$-submodule of $H_{n}(X)$ generated by the classes [ $L_{J, \beta}$ ] of all standard $d$-spaces.

[^0]In the case $n=2$, the problem to determine whether $\mathcal{L}(X)$ is primitive in $H_{n}(X)$ or not was raised by Aoki and Shioda [1] in the study of the Picard groups of Fermat surfaces. In degrees $m$ prime to 6 , the primitivity of $\mathcal{L}(X)$ implies that the Picard group of $X$ is generated by the classes of the lines contained in $X$. Schütt, Shioda and van Luijk [7] studied this problem using the reduction of $X$ at supersingular primes. Recently, the first author of the present article solved in [3] this problem affirmatively by means of the Galois covering $X \rightarrow \mathbb{P}^{2}$ and the method of Alexander modules.

The purpose of this paper is to study the subgroup $\mathcal{L}(X) \subset H_{n}(X)$ for higherdimensional Fermat varieties. For a non-empty subset $\mathcal{K}$ of $\mathcal{J}$, we denote by $\mathcal{L}_{\mathcal{K}}(X)$ the $\mathbb{Z}$-submodule of $H_{n}(X)$ generated by the classes $\left[L_{J, \beta}\right]$, where $J \in \mathcal{K}$ and $\beta \in \mathcal{B}$.

To state our results, we prepare several polynomials in $\mathbb{Z}\left[t_{1}, \ldots, t_{n+1}\right]$, rings, and modules. We put

$$
\phi(t):=t^{m-1}+\cdots+t+1, \quad \rho(x, y):=\sum_{\mu=0}^{m-2} x^{\mu}\left(\sum_{\nu=0}^{\mu} y^{\nu}\right)
$$

For $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{J}$, we put

$$
\begin{aligned}
\tau_{J} & :=\left(t_{k_{0}}-1\right) \cdots\left(t_{k_{d}}-1\right), \\
\psi_{J} & :=\tau_{J} \cdot \phi\left(t_{j_{1}} t_{k_{1}}\right) \cdots \phi\left(t_{j_{d}} t_{k_{d}}\right), \\
\rho_{J} & :=\rho\left(t_{j_{1}}, t_{k_{1}}\right) \cdots \rho\left(t_{j_{d}}, t_{k_{d}}\right) .
\end{aligned}
$$

Consider the ring

$$
\Lambda:=\mathbb{Z}\left[t_{0}^{ \pm 1}, \ldots, t_{n+1}^{ \pm 1}\right] /\left(t_{0} \ldots t_{n+1}-1\right)=\mathbb{Z}\left[t_{1}^{ \pm 1}, \ldots, t_{n+1}^{ \pm 1}\right]
$$

of Laurent polynomials and let

$$
\begin{aligned}
& R:=\Lambda /\left(t_{0}^{m}-1, \ldots, t_{n+1}^{m}-1\right)=\mathbb{Z}\left[t_{1}, \ldots, t_{n+1}\right] /\left(t_{1}^{m}-1, \ldots, t_{n+1}^{m}-1\right) \\
& \bar{R}:=R /\left(\phi\left(t_{0}\right), \ldots, \phi\left(t_{n+1}\right)\right)=\mathbb{Z}\left[t_{1}, \ldots, t_{n+1}\right] /\left(\phi\left(t_{1}\right), \ldots, \phi\left(t_{n+1}\right)\right)
\end{aligned}
$$

For $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{J}$, we put

$$
\begin{aligned}
& R_{J}:=R /\left(t_{j_{1}} t_{k_{1}}-1, \ldots, t_{j_{d}} t_{k_{d}}-1\right), \\
& \bar{R}_{J}:=\bar{R} /\left(t_{j_{1}} t_{k_{1}}-1, \ldots, t_{j_{d}} t_{k_{d}}-1\right) .
\end{aligned}
$$

Note that we always have $t_{j_{0}} t_{k_{0}}-1=0$ in $R_{J}$ and $\bar{R}_{J}$. The multiplicative identities of these rings, i.e., the images of $1 \in \Lambda$ under the quotient projection, are denoted by $1_{J}$.

Our primary concern is the structure of the abelian group $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X)$. For this reason, whenever speaking about the torsion of an abelian group $A$, we always mean its $\mathbb{Z}$-torsion Tors $A:=\operatorname{Tors}_{\mathbb{Z}} A$, even if $A$ happens to be an $R$ - or $\bar{R}$-module. (Over $R$, almost all our modules have torsion.) Respectively, $A$ is said to be torsion free if its $\mathbb{Z}$-torsion $\operatorname{Tors}_{\mathbb{Z}} A$ is trivial.

Our main results are as follows.
Theorem 1.1 (see Section 4). Let $\mathcal{K}$ be a non-empty subset of $\mathcal{J}$. Then the torsion of the quotient module $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X)$ is isomorphic to the torsions of any of the following modules:
(a) the ring $R /\left(\psi_{J} \mid J \in \mathcal{K}\right)$, where $\left(\psi_{J} \mid J \in \mathcal{K}\right)$ is the ideal of $R$ generated by $\psi_{J}$ with $J$ running through $\mathcal{K}$,
(b) the ring $\bar{R} /\left(\rho_{J} \mid J \in \mathcal{K}\right)$, where $\left(\rho_{J} \mid J \in \mathcal{K}\right)$ is the ideal of $\bar{R}$ generated by $\rho_{J}$ with $J$ running through $\mathcal{K}$,
(c) the $R$-module

$$
\mathcal{C}_{\mathcal{K}}:=\left(\bigoplus_{J \in \mathcal{K}} R_{J}\right) / \mathcal{M}
$$

where $\mathcal{M}$ is the $R$-submodule of $\bigoplus_{J \in \mathcal{K}} R_{J}$ generated by $\sum_{J \in \mathcal{K}} \tau_{J} 1_{J}$,
(d) the $\bar{R}$-module

$$
\overline{\mathcal{C}}_{\mathcal{K}}:=\left(\bigoplus_{J \in \mathcal{K}} \bar{R}_{J}\right) / \overline{\mathcal{M}}
$$

where $\overline{\mathcal{M}}$ is the $\bar{R}$-submodule of $\bigoplus_{J \in \mathcal{K}} \bar{R}_{J}$ generated by $\sum_{J \in \mathcal{K}} 1_{J}$.
In particular, we assert that the torsion parts of all four modules listed in Theorem 1.1 are isomorphic, although not always canonically: sometimes, we use the abstract isomorphism $A \cong \operatorname{Hom}_{\mathbb{Z}}(A, \mathbb{Q} / \mathbb{Z})$ for a finite abelian group $A$, see Section 4.5 for details. It is worth mentioning that, according to [4], in the case $d=2$ of Fermat surfaces, the a priori more complicated module dealt with in [3] (which was found by means of a completely different approach) is isomorphic to the one that is given in Theorem 1.1 (c).

Conjecture 1.2. If $\mathcal{K}=\mathcal{J}$, the group $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X)$ is torsion free.
This conjecture is supported by some numerical evidence (see Section 5 for details) and by the fact that it holds in the cases $d=0$ (obvious) and $d=1$ (see [3]). Theorem 1.1 reduces Conjecture 1.2 to a purely algebraic (or even combinatorial) question. However, for the moment it remains open.

Definition 1.3. Let $\mu_{m}$ be the subgroup $\left\{z \in \mathbb{C} \mid z^{m}=1\right\}$ of $\mathbb{C}^{\times}$. Denote by $\Gamma_{\mathcal{K}}$ the subset of $\mu_{m}^{n+1}=\operatorname{Spec}(R \otimes \mathbb{C})$ consisting of the elements $\left(a_{1}, \ldots, a_{n+1}\right) \in \mu_{m}^{n+1}$ such that $a_{i} \neq 1$ for $i=1, \ldots, n+1$ and that there exists $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{K}$ such that $a_{j_{i}} a_{k_{i}}=1$ hold for $i=1, \ldots, d$.

Theorem 1.4 (see Section 4.3). For any non-empty subset $\mathcal{K}$ of $\mathcal{J}$, the rank of the group $\mathcal{L}_{\mathcal{K}}(X)$ is equal to $\left|\Gamma_{\mathcal{K}}\right|+1$.

As a corollary, we obtain the following statement, which is a higher-dimensional generalization of Corollary 4.4 of [7]:

Corollary 1.5 (see Section 4.3). For any non-empty subset $\mathcal{K}$ of $\mathcal{J}$, the order of the torsion of $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X)$ may be divisible only by those primes that divide $m$.

Applying Theorem 1.1 to a subset $\mathcal{K}$ consisting of a single element and using a deformation from $X$, we also prove the following generalization of Theorem 1.4 of [3]. Let $f_{i}(x, y)$ be a homogeneous binary form of degree $m$ for $i=0, \ldots, d$. Suppose that the hypersurface $W$ in $\mathbb{P}^{n+1}$ defined by

$$
\begin{equation*}
f_{0}\left(z_{0}, z_{1}\right)+f_{1}\left(z_{2}, z_{3}\right)+\cdots+f_{d}\left(z_{n}, z_{n+1}\right)=0 \tag{1.3}
\end{equation*}
$$

is smooth. Then each $f_{i}(x, y)=0$ has $m$ distinct zeros $\left(\alpha_{1}^{(i)}: \beta_{1}^{(i)}\right), \ldots,\left(\alpha_{m}^{(i)}: \beta_{m}^{(i)}\right)$ on $\mathbb{P}^{1}$. Consider the points

$$
P_{\nu}^{(i)}:=\left(0: \cdots: \underset{(2 i)}{\alpha_{\nu}^{(i)}}: \underset{\substack{(2 i+1)}}{\beta_{\nu}^{(i)}}: \cdots: 0\right)
$$

of $\mathbb{P}^{n+1}$. Then, for each $(d+1)$-tuple $\left(\nu_{0}, \ldots, \nu_{d}\right)$ of integers $\nu_{i}$ with $1 \leq \nu_{i} \leq m$, the $d$-space $L_{\left(\nu_{0}, \ldots, \nu_{d}\right)}^{\prime}$ spanned by $P_{\nu_{0}}^{(0)}, \ldots, P_{\nu_{d}}^{(d)}$ is contained in $W$.

Corollary 1.6 (see Section 4.6). The submodule of $H_{n}(W)$ generated by the classes $\left[L_{\left(\nu_{0}, \ldots, \nu_{d}\right)}^{\prime}\right]$ of the $m^{d+1}$ subspaces $L_{\left(\nu_{0}, \ldots, \nu_{d}\right)}^{\prime}$ contained in $W$ is of $\operatorname{rank}(m-1)^{d+1}$ +1 and is primitive in $H_{n}(W)$.

The last statement can further be extended to what we call a partial Fermat variety, i.e., a hypersurface $W_{s} \subset \mathbb{P}^{n+1}$ given by equation (1.3) with

$$
f_{0}(x, y)=\cdots=f_{s}(x, y)=x^{m}+y^{m}
$$

and the remaining polynomials distinct (pairwise and from $x^{m}+y^{m}$ ) and generic. Such a variety contains $(2 s+1)!!m^{d+1}$ projective linear subspaces $L_{*}^{\prime}$ of dimension $d$ : each subspace can be obtained as the projective span of one of the $s$-spaces in the Fermat variety

$$
X(2 s):=W_{s} \cap\left\{z_{2 s+2}=\cdots=z_{n+1}=0\right\} \subset \mathbb{P}^{2 s+1}
$$

and one of the $(d-s)$-tuples of points $P_{\nu_{s+1}}^{(s+1)}, \ldots, P_{\nu_{d}}^{(d)}$ as above. Then, we have the following conditional statement.

Corollary 1.7 (see Section 4.6). Assume that the statement of Conjecture 1.2 holds for Fermat varieties of dimension $2 s \geq 0$. Then, for any $d \geq s$, the submodule of $H_{n}\left(W_{s}\right)$ generated by the classes $\left[L_{*}^{\prime}\right]$ of the subspaces $L_{*}^{\prime}$ contained in $W_{s}$ is primitive in $H_{n}\left(W_{s}\right)$. In particular, this submodule is primitive for $s=0$ or 1 .

We conclude this introductory section with a very brief outline of the other developments related to the subject.

In $[\mathbf{1 0}]$ and $[\mathbf{1 2}]$, the $\mathbb{Q}$-Hodge structure on the rational cohomology $H^{n}(X, \mathbb{Q})$ was
intensively investigated. Letting $\zeta:=e^{2 \pi \sqrt{-1} / m}$, the tensor product $H^{n}(X) \otimes \mathbb{Q}(\zeta)$ decomposes into simple representations of a certain abelian group $G$ (see Section 2 below), which are all of dimension 1 and pairwise distinct. This decomposition is compatible with the Hodge filtration, and the Hodge indices of the summands are computed explicitly. As a by-product of this computation, one concludes that, at least if the degree $m$ is a prime, the space of rational Hodge classes $H^{d, d}(X) \cap H^{n}(X, \mathbb{Q})$ is generated by the classes of the standard $d$-spaces. (See also Ran [6].) (In the special case $d=1$ of surfaces, this rational generation property holds for all degrees prime to 6.) It is this fact that motivates our work and makes the study of the torsion of the quotient $H_{n}(X) / \mathcal{L}_{\mathcal{J}}(X)$ particularly important: if this torsion is trivial, the classes of the standard $d$-spaces generate the $\mathbb{Z}$-module of integral Hodge classes $H^{d, d}(X) \cap H^{n}(X, \mathbb{Z})$.

In [8], we investigated the Fermat variety $X_{q+1}$ of even dimension and degree $q+1$ in characteristic $p>0$, where $q$ is a power of $p$. By considering the middle-dimensional subspaces contained in $X_{q+1}$, we showed that the discriminant of the lattice of numerical equivalence classes of middle-dimensional algebraic cycles of $X_{q+1}$ is a power of $p$. Note that the rank of this lattice is equal to the middle Betti number of $X_{q+1}$, that is, $X_{q+1}$ is supersingular.

In [9], we suggested a general method to calculate the primitive closure in $H^{2}(Y)$ of the lattice generated by the classes of given curves on a complex algebraic surface $Y$. As an example, we applied this method to certain branched covers of the complex projective plane.

In [4], the method of [3] was generalized to the calculation of the Picard groups of the so-called Delsarte surfaces $Y$. More precisely, the computation of the Picard rank was suggested in [11], and [4] deals with the (im-)primitivity of the subgroup $\mathcal{L}(Y) \subset H_{2}(Y)$ generated by the classes of certain "obvious" divisors. In a few cases, this subgroup is primitive, but as a rule the quotient $H_{2}(Y) / \mathcal{L}(Y)$ does have a certain controlled torsion.

Acknowledgements. The authors heartily thank Professor Tetsuji Shioda for many discussions. This work was partially completed during the first author's visit to Hiroshima University; we extend our gratitude to this institution for its great hospitality.

Notation. By $(a, \ldots, b, \ldots a)$, we denote a vector whose $i$ th coordinate is $b$ and other coordinates are $a$. The hat ^ means omission of an element; for example, by $\left(a_{1}, \ldots, \hat{a_{i}}, \ldots, a_{N}\right)$, we denote the vector $\left(a_{1}, \ldots, a_{i-1}, a_{i+1} \ldots, a_{N}\right)$.

## 2. An outline of the proof.

To avoid confusion, let us denote by $\mathbf{P}^{n+1}$ another copy of the projective space, the one with homogeneous coordinates $\left(w_{0}: \cdots: w_{n+1}\right)$. (Below, we will also use $\mathbf{C}^{n+1}$ for an affine chart of $\mathbf{P}^{n+1}$.) In $\mathbf{P}^{n+1}$, consider the hyperplane $\Pi$ defined by

$$
w_{0}+\cdots+w_{n+1}=0 .
$$

Then we have the Galois covering $\pi: X \rightarrow \Pi$ defined by

$$
\left(z_{0}: \cdots: z_{n+1}\right) \mapsto\left(z_{0}^{m}: \cdots: z_{n+1}^{m}\right)
$$

We put $\zeta:=e^{2 \pi \sqrt{-1} / m}$. Then the Galois group $G$ of $\pi$ is generated by

$$
\gamma_{i}:\left(z_{0}: \cdots: z_{i}: \cdots: z_{n+1}\right) \mapsto\left(z_{0}: \cdots: \zeta z_{i}: \cdots: z_{n+1}\right)
$$

for $i=0, \ldots, n+1$. Since $\gamma_{0} \cdots \gamma_{n+1}=1$, this group $G$ is isomorphic to $(\mathbb{Z} / m \mathbb{Z})^{n+1}$. Throughout this paper, we regard $R$ as the group ring $\mathbb{Z}[G]$ by corresponding $\gamma_{i} \in G$ to the variable $t_{i}$ for $i=1, \ldots, n+1$, and $\gamma_{0} \in G$ to $t_{0}=t_{1}^{-1} \cdots t_{n+1}^{-1}$. Then we can regard $H_{n}(X)$ as an $R$-module. Note that, for any subset $\mathcal{K}$ of $\mathcal{J}$, the subgroup $\mathcal{L}_{\mathcal{K}}(X)$ of $H_{n}(X)$ is in fact an $R$-submodule, because, for any $J \in \mathcal{J}, g \in G$, and $\beta \in \mathcal{B}$, there exists $\beta^{\prime} \in \mathcal{B}$ such that $g\left(L_{J, \beta}\right)=L_{J, \beta^{\prime}}$.

Let $Y_{0}$ be the hyperplane section of $X$ defined by $\left\{z_{0}=0\right\}$, which is $G$-invariant. Since the fundamental classes $[X] \in H_{2 n}(X)$ and $\left[Y_{0}\right] \in H_{2 n-2}\left(Y_{0}\right)$ are also fixed by $G$, the Poincaré-Lefschetz duality isomorphisms

$$
H_{n}\left(X \backslash Y_{0}\right)=H^{n}\left(X, Y_{0}\right), \quad H_{2 n-i}(X)=H^{i}(X), \quad H_{2 n-2-i}\left(Y_{0}\right)=H^{i}\left(Y_{0}\right)
$$

are $R$-linear; hence, they convert the cohomology exact sequence of the pair $(X, Y)$ into a long exact sequence of $R$-modules

$$
\begin{equation*}
\cdots \rightarrow H_{n-1}\left(Y_{0}\right) \xrightarrow{\partial} H_{n}\left(X \backslash Y_{0}\right) \xrightarrow{\iota_{*}} H_{n}(X) \rightarrow H_{n-2}\left(Y_{0}\right) \rightarrow \cdots \tag{2.1}
\end{equation*}
$$

where $\iota: X \backslash Y_{0} \hookrightarrow X$ is the inclusion. We then put

$$
V_{n}(X):=\operatorname{Im}\left(\iota_{*}: H_{n}\left(X \backslash Y_{0}\right) \rightarrow H_{n}(X)\right)
$$

Since the group $H_{n-2}\left(Y_{0}\right)$ is torsion free, the $R$-submodule $V_{n}(X)$ of $H_{n}(X)$ is primitive in $H_{n}(X)$ as a $\mathbb{Z}$-submodule.

The structure of the $R$-module $V_{n}(X)$ is given by the theory of Pham polyhedron developed in [5]. Let $z_{0}=1$ and regard $\left(z_{1}, \ldots, z_{n+1}\right)$ as affine coordinates on the affine space $\mathbb{C}^{n+1}:=\mathbb{P}^{n+1} \backslash\left\{z_{0}=0\right\}$, in which $X \backslash Y_{0}$ is defined by

$$
1+z_{1}^{m}+\cdots+z_{n+1}^{m}=0
$$

Fix the $m$-th root $\eta:=e^{\pi \sqrt{-1} / m}$ of -1 , and consider the (topological) $n$-simplex

$$
D:=\left\{\left(s_{1} \eta, \ldots, s_{n+1} \eta\right) \mid s_{i} \in \mathbb{R}, \quad s_{1}^{m}+\cdots+s_{n+1}^{m}=1, \quad 0 \leq s_{i} \leq 1\right\}
$$

in $X \backslash Y_{0}$, oriented so that that, if we consider $\left(s_{1}, \ldots, s_{n}\right)$ as local real coordinates of $D$ at an interior point of $D$, then

$$
\left(-\partial / \partial s_{1}, \ldots,-\partial / \partial s_{n}\right)
$$

is a positively-oriented basis of the real tangent space of $D$ at this point. Then it is easy
to see that the chain

$$
S:=\left(1-\gamma_{1}^{-1}\right) \cdots\left(1-\gamma_{n+1}^{-1}\right) D
$$

is a cycle; moreover, it is homeomorphic to the join of $(n+1)$ copies of the two-point space $\{\eta, \zeta \eta\}$, i.e., to the $n$-sphere. (Here and below, we do not distinguish between "simple" singular chains in $X$ and the corresponding geometric objects, viz. unions of simplices with the orientation taken into account and the common parts of the boundary identified. For this reason, we freely apply the module notation to simplices.) Hence, we have the class $[S] \in H_{n}\left(X \backslash Y_{0}\right)$ and its image $[S] \in V_{n}(X)$ by $\iota_{*}$. Pham [5] proved the following:

Theorem 2.1 (see [5]). The homomorphism $1 \mapsto[S]$ from $R$ to $H_{n}\left(X \backslash Y_{0}\right)$ induces an isomorphism $\bar{R} \cong H_{n}\left(X \backslash Y_{0}\right)$ of $R$-modules, and hence a surjective homomorphism $R \rightarrow V_{n}(X)$ of $R$-modules.

The Poincaré duality gives rise to symmetric bilinear pairings $\langle$,$\rangle on the groups$ $H_{n}\left(X \backslash Y_{0}\right), V_{n}(X)$, and $H_{n}(X)$, which is interpreted geometrically as the signed intersection of $n$-cycles brought to a general position. We emphasize that these pairings are $\mathbb{Z}$-bilinear and $G$-invariant (as so is the fundamental class $[X]$ ). The homomorphisms $H_{n}\left(X \backslash Y_{0}\right) \rightarrow V_{n}(X) \hookrightarrow H_{n}(X)$ preserve $\langle$,$\rangle . Note that \langle$,$\rangle is non-degenerate on$ $H_{n}(X)$, but not on $H_{n}\left(X \backslash Y_{0}\right)$. Later, we will see that $\langle$,$\rangle is also nondegenerate on$ $V_{n}(X)$.

The main ingredient of the proof of Theorems 1.1 and 1.4 is the following:
Theorem 2.2 (see Section 3). For $\beta_{i} \in \mathbb{C}^{\times}$with $\beta_{i}^{m}=-1$, we put

$$
s\left(\beta_{i}\right):= \begin{cases}1 & \text { if } \beta_{i}=\eta \\ -1 & \text { if } \beta_{i}=\eta^{-1} \\ 0 & \text { otherwise }\end{cases}
$$

(Recall that we fixed $\eta:=e^{\pi \sqrt{-1} / m}$.) For $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{J}$ ordered as in (1.1), let $\sigma_{J}$ be the permutation

$$
\left(\begin{array}{ccccc}
0 & 1 & \cdots & n & n+1 \\
j_{0} & k_{0} & \cdots & j_{d} & k_{d}
\end{array}\right) .
$$

Then we have

$$
\left\langle L_{J, \beta}, S\right\rangle=\operatorname{sgn}\left(\sigma_{J}\right) s\left(\beta_{0}\right) \cdots s\left(\beta_{d}\right),
$$

where $\beta=\left(\beta_{0}, \ldots, \beta_{d}\right) \in \mathcal{B}$.
We use Theorem 2.2 and the fact that the pairing on $H_{n}(X)$ is nondegenerate to compute the subgroup $\mathcal{L}_{\mathcal{K}}(X) \subset H_{n}(X)$. Various stages of this computation result in most principal statements of the paper.

## 3. Intersection of $S$ and the standard $d$-spaces.

In this section, we prove Theorem 2.2. The affine part $X \backslash Y_{0}$ of $X$ is defined by $1+z_{1}^{m}+\cdots+z_{n+1}^{m}=0$ in the affine space $\mathbb{C}^{n+1}$ with coordinates $\left(z_{1}, \ldots, z_{n+1}\right)$. We put

$$
\mathbf{C}^{n+1}:=\mathbf{P}^{n+1} \backslash\left\{w_{0}=0\right\}
$$

and setting $w_{0}=1$, we regard $\left(w_{1}, \ldots, w_{n+1}\right)$ as affine coordinates of $\mathbf{C}^{n+1}$. We put

$$
z_{i}=x_{i}+\sqrt{-1} y_{i}, \quad w_{i}=u_{i}+\sqrt{-1} v_{i}
$$

where $x_{i}, y_{i}, u_{i}, v_{i}$ are real coordinates. Consider the affine hyperplane

$$
\Pi^{\circ}:=\Pi \cap \mathbf{C}^{n+1}=\left\{1+w_{1}+\cdots+w_{n+1}=0\right\}
$$

of $\mathbf{C}^{n+1}$. In the real part

$$
\Pi^{\circ} \cap\left\{v_{1}=\cdots=v_{n+1}=0\right\}=\left\{\left(u_{1}, \ldots, u_{n+1}\right) \in \mathbf{R}^{n+1} \mid 1+u_{1}+\cdots+u_{n+1}=0\right\}
$$

of $\Pi^{\circ}$, we have an $n$-simplex $\Delta$ defined by

$$
1+u_{1}+\cdots+u_{n+1}=0 \quad \text { and } \quad-1 \leq u_{i} \leq 0 \text { for } i=1, \ldots, n+1
$$

Then $\pi: X \rightarrow \Pi$ induces a homeomorphism $\left.\pi\right|_{D}: D \xrightarrow{\sim} \Delta$. We put

$$
\begin{equation*}
p_{i}:=(0, \ldots, \underset{(i)}{\eta}, \ldots 0) \in D, \tag{i}
\end{equation*}
$$

and put $\bar{p}_{i}:=\pi\left(p_{i}\right)=(0, \ldots,-1, \ldots, 0)$. Then $\bar{p}_{1}, \ldots, \bar{p}_{n+1}$ are the vertices of $\Delta$.
Remark 3.1. Note that $S \subset \pi^{-1}(\Delta)$, and that

$$
S \cap \pi^{-1}\left(\left\{\bar{p}_{1}, \ldots, \bar{p}_{n+1}\right\}\right)=\left\{p_{1}, \gamma_{1}^{-1}\left(p_{1}\right), \ldots, p_{n+1}, \gamma_{n+1}^{-1}\left(p_{n+1}\right)\right\} .
$$

Remark 3.2. By the definition of the orientation of $D$ given in Section 2, we see that, locally at $p_{i}$, the $n$-chain $D$ is identified with the product

$$
(-1)^{i+1} \overrightarrow{p_{i} p_{1}} \times \cdots \times \overrightarrow{p_{i} p_{i-1}} \times \overrightarrow{p_{i} p_{i+1}} \times \cdots \times \overrightarrow{p_{i} p_{n+1}}
$$

of 1-chains, where $\overrightarrow{p_{i} p_{k}}$ is the 1-dimensional edge of $D$ connecting $p_{i}$ and $p_{k}$ and oriented from $p_{i}$ to $p_{k}$.

By the condition (1.1) on $\mathcal{J}$, we always have $j_{0}=0$. Let $b_{0}$ be an element of $\mathbb{Z} / m \mathbb{Z}$ such that

$$
\beta_{0}=\eta^{1+2 b_{0}}=\zeta^{b_{0}} \eta .
$$

In the affine coordinates $\left(z_{1}, \ldots, z_{n+1}\right)$ of $\mathbb{C}^{n+1}$, the equations (1.2) of $L_{J, \beta}$ are written as

$$
\begin{equation*}
z_{k_{0}}=\beta_{0}, \quad z_{k_{i}}=\beta_{i} z_{j_{i}} \quad(i=1, \ldots, d) . \tag{3.1}
\end{equation*}
$$

If (3.1) holds, then we have $z_{k_{i}}^{m}=-z_{j_{i}}^{m}$ for $i=1, \ldots, d$, and hence $L_{J, \beta} \cap \pi^{-1}(\Delta)$ consists of a single point

$$
\left(0, \ldots, \underset{\left(k_{0}\right)}{\beta_{0}}, \ldots 0\right)=\gamma_{k_{0}}^{b_{0}}\left(p_{k_{0}}\right)
$$

by Remark 3.1. Therefore, we have

$$
L_{J, \beta} \cap S= \begin{cases}\emptyset & \text { if } \beta_{0} \neq \eta \text { and } \beta_{0} \neq \eta^{-1}, \\ \left\{p_{k_{0}}\right\} & \text { if } \beta_{0}=\eta, \\ \left\{\gamma_{k_{0}}^{-1}\left(p_{k_{0}}\right)\right\} & \text { if } \beta_{0}=\eta^{-1} .\end{cases}
$$

In particular, we have

$$
\begin{equation*}
\left\langle L_{J, \beta}, S\right\rangle=0 \quad \text { if } \beta_{0} \neq \eta \text { and } \beta_{0} \neq \eta^{-1} . \tag{3.2}
\end{equation*}
$$

In order to calculate $\left\langle L_{J, \beta}, S\right\rangle$ in the cases where $\beta_{0}=\eta^{ \pm 1}$, we need the following lemma. For an angle $\theta$, we consider the oriented real semi-line

$$
H(\theta):=\mathbb{R}_{\geq 0} e^{\sqrt{-1} \theta} \quad \text { with the orientation from } 0 \text { to } e^{\sqrt{-1} \theta}
$$

on the complex plane $\mathbb{C}$, and define the chain (with closed support)

$$
W(\theta):=H(\theta)-H(\theta-2 \pi / m)=\left(1-\gamma^{-1}\right) H(\theta),
$$

where $\gamma: \mathbb{C} \rightarrow \mathbb{C}$ is the multiplication by $\zeta=e^{2 \pi \sqrt{-1} / m}$. Note that $W(\pi / m)=H(\pi / m)-$ $H(-\pi / m)$. Let $\mathbb{C}^{2}$ be equipped with coordinates $\left(z, z^{\prime}\right)$. For $\beta_{i} \in \mathbb{C}$ with $\beta_{i}^{m}=-1$, we denote by $\Lambda_{\beta_{i}}$ the linear subspace of $\mathbb{C}^{2}$ defined by $z^{\prime}=\beta_{i} z$.

Lemma 3.3. The local intersection number $\ell\left(\beta_{i}\right)$ at the origin in $\mathbb{C}^{2}$ of the chains $W(\pi / m) \times W(\pi / m)$ and $\Lambda_{\beta_{i}}$ is equal to $s\left(\beta_{i}\right)$.

Proof. The linear subspace $\Lambda_{\beta_{i}}$ is the graph of the function $f: z \mapsto z^{\prime}=\beta_{i} z$, and hence $f(W(\pi / m))$ is obtained by rotating $W(\pi / m)$ by $\beta_{i} \in \mathbb{C}^{\times}$. Let $\varepsilon$ and $\varepsilon^{\prime}$ be sufficiently small positive real numbers. We perturb $\Lambda_{\beta_{i}}$ locally at the origin to the graph $\tilde{\Lambda}_{\beta_{i}}$ of the function

$$
\tilde{f}: z \mapsto z^{\prime}=\beta_{i} z+\varepsilon e^{\sqrt{-1} \tau} \rho(|z|),
$$

where $\rho: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$ is the function

$$
\rho(x)= \begin{cases}1 & \text { if } x \leq \varepsilon^{\prime} \\ 2-x / \varepsilon^{\prime} & \text { if } \varepsilon^{\prime} \leq x \leq 2 \varepsilon^{\prime} \\ 0 & \text { if } 2 \varepsilon^{\prime} \leq x\end{cases}
$$

The direction $\tau$ of the perturbation is given as in Figure 3.1, where $W(\pi / m)$ are drawn by thick arrows, $f(W(\pi / m))$ are drawn by thin arrows and $\tilde{f}(W(\pi / m))$ are drawn by broken arrows.

Figure 3.1. $\quad W(\pi / m), f(W(\pi / m))$ and $\tilde{f}(W(\pi / m))$.
Suppose that $\beta_{i} \neq \eta$ and $\beta_{i} \neq \eta^{-1}$. As Figure 3.1 illustrates in the case $\beta_{i}=\eta^{3}$, we see that $\tilde{f}(W(\pi / m))$ and $W(\pi / m)$ are disjoint, and hence

$$
\tilde{\Lambda}_{\beta_{i}} \cap(W(\pi / m) \times W(\pi / m))=\emptyset
$$

Therefore $\ell\left(\beta_{i}\right)=0$.
Suppose that $\beta_{i}=\eta$. Then the intersection of $\tilde{\Lambda}_{\eta}$ and $W(\pi / m) \times W(\pi / m)$ consists of a single point $(Q, \tilde{f}(Q))$, where $Q \in H(-\pi / m)$ and $\tilde{f}(Q) \in H(\pi / m)$. We choose a positively-oriented basis of the real tangent space of $\mathbb{C}^{2}$ at this point as

$$
\left(\partial / \partial x, \partial / \partial y, \partial / \partial x^{\prime}, \partial / \partial y^{\prime}\right), \quad \text { where } \quad z=x+\sqrt{-1} y, \quad z^{\prime}=x^{\prime}+\sqrt{-1} y^{\prime}
$$

The positively-oriented basis of the tangent space of $\tilde{\Lambda}_{\eta}$ at $(Q, \tilde{f}(Q))$ is

$$
(1,0, \cos (\pi / m), \sin (\pi / m)), \quad(0,1,-\sin (\pi / m), \cos (\pi / m))
$$

while the positively-oriented basis of the tangent space of $W(\pi / m) \times W(\pi / m)$ at $(Q, \tilde{f}(Q)) \in H(-\pi / m) \times H(\pi / m)$ is

$$
(-\cos (-\pi / m),-\sin (-\pi / m), 0,0), \quad(0,0, \cos (\pi / m), \sin (\pi / m))
$$

(Note that $W(\pi / m)$ is oriented toward the origin on $H(-\pi / m)$.) Calculating the sign of the determinant of the $4 \times 4$ matrix with row vectors being the four vectors above in this order, we see that $\ell(\eta)=1$.

Suppose that $\beta_{i}=\eta^{-1}$. Then $\tilde{\Lambda}_{\eta^{-1}} \cap W(\pi / m) \times W(\pi / m)$ consists of a single point $(Q, \tilde{f}(Q))$, where $Q \in H(\pi / m)$ and $\tilde{f}(Q) \in H(-\pi / m)$. The positively-oriented basis of the tangent space of $\tilde{\Lambda}_{\eta^{-1}}$ at $(Q, \tilde{f}(Q))$ is

$$
(1,0, \cos (-\pi / m), \sin (-\pi / m)), \quad(0,1,-\sin (-\pi / m), \cos (-\pi / m))
$$

while that of $W(\pi / m) \times W(\pi / m)$ at $(Q, \tilde{f}(Q)) \in H(\pi / m) \times H(-\pi / m)$ is

$$
(\cos (\pi / m), \sin (\pi / m), 0,0), \quad(0,0,-\cos (-\pi / m),-\sin (-\pi / m))
$$

Calculating the determinant, we see that $\ell\left(\eta^{-1}\right)=-1$.
Let $p$ be $p_{i}$ or $\gamma_{i}^{-1}\left(p_{i}\right)$. In a small neighborhood $\mathcal{U}_{p}$ of $p$ in $X \backslash Y_{0}$, we have local coordinates $\left(z_{1}, \ldots, \hat{z}_{i}, \ldots, z_{n+1}\right)$ of $X \backslash Y_{0}$. Let

$$
\iota_{p}: \mathcal{U}_{p} \hookrightarrow \mathbb{C} \times \cdots \times \mathbb{C} \quad(n \text { factors })
$$

be the open immersion defined by $\left(z_{1}, \ldots, \hat{z}_{i}, \ldots, z_{n+1}\right)$. We consider an element

$$
g:=\gamma_{1}^{\nu_{1}} \cdots \gamma_{n+1}^{\nu_{n+1}} \in G
$$

and give a local description of $g(D)$ at $p=p_{i}$ and $p=\gamma_{i}^{-1}\left(p_{i}\right)$ via $\iota_{p}$.
(1) Locally around $p=p_{i}$. If $\nu_{i} \neq 0$, then $p_{i} \notin g(D)$ and hence $\mathcal{U}_{p} \cap g(D)=\emptyset$. Suppose that $\nu_{i}=0$. Using Remark 3.2 and the fact that $g$ preserves the orientation, we see that $g(D)$ is identified with

$$
\begin{align*}
& (-1)^{i+1} H\left(\left(2 \nu_{1}+1\right) \pi / m\right) \times \cdots \times H\left(\left(2 \nu_{i-1}+1\right) \pi / m\right) \\
& \left.\left.\quad \times H\left(\left(2 \nu_{i+1}+1\right) \pi\right) / m\right) \times \cdots \times H\left(\left(2 \nu_{n+1}+1\right) \pi\right) / m\right) \tag{3.3}
\end{align*}
$$

(2) Locally around $p=\gamma^{-1}\left(p_{i}\right)$. If $\nu_{i} \neq-1$, then $\gamma^{-1}\left(p_{i}\right) \notin g(D)$ and hence $\mathcal{U}_{p} \cap g(D)$ is empty. Suppose that $\nu_{i}=-1$. Then $g(D)$ is identified with (3.3) because the action of $\gamma_{i}$ maps the local descriptions of $g(D)$ at $\gamma_{i}^{-1}\left(p_{i}\right)$ to that of $\gamma_{i} g(D)$ at $p_{i}$.

We put

$$
S_{i}:=\left(1-\gamma_{1}^{-1}\right) \cdots\left(1-\gamma_{i-1}^{-1}\right)\left(1-\gamma_{i+1}^{-1}\right) \cdots\left(1-\gamma_{n+1}^{-1}\right) D
$$

(note that $\gamma_{i}$ is missing), which is a hemisphere of the $n$-sphere $S$ containing $p_{i}$. The other hemisphere is $\gamma_{i}^{-1}\left(S_{i}\right)$, and we have $S=S_{i}-\gamma_{i}^{-1}\left(S_{i}\right)$. Since $p_{i} \in S_{i}$ and $p_{i} \notin \gamma_{i}^{-1}\left(S_{i}\right)$, $S$ is identified with

$$
(-1)^{i+1} W(\pi / m) \times \cdots \times W(\pi / m)
$$

locally at $p_{i}$ by $\iota_{p_{i}}$; while since $\gamma_{i}^{-1}\left(p_{i}\right) \notin S_{i}$ and $\gamma_{i}^{-1}\left(p_{i}\right) \in \gamma_{i}^{-1}\left(S_{i}\right), S$ is identified with

$$
-(-1)^{i+1} W(\pi / m) \times \cdots \times W(\pi / m)
$$

locally at $\gamma_{i}^{-1}\left(p_{i}\right)$ by $\iota_{\gamma_{i}^{-1}\left(p_{i}\right)}$.
Suppose that $\beta_{0}=\eta$. We calculate the local intersection number of $L_{J, \beta}$ and $S$ at $p:=p_{k_{0}}$. As was shown above, the topological $n$-cycle $S$ is identified locally at $p$ with

$$
(-1)^{k_{0}+1} W(\pi / m) \times \cdots \times W(\pi / m)
$$

by the local coordinates $\left(z_{1}, \ldots, z_{\hat{k}_{0}}, \ldots, z_{n+1}\right)$ of $X \backslash Y_{0}$ with the origin $p$. Note that $\left\{1, \ldots, \hat{k_{0}}, \ldots, n+1\right\}$ is equal to $\left\{j_{1}, k_{1}, \ldots, j_{d}, k_{d}\right\}$. We permute the coordinate system $\left(z_{1}, \ldots, z_{\hat{k}_{0}}, \ldots, z_{n+1}\right)$ to

$$
\left(z_{j_{1}}, z_{k_{1}}, \ldots, z_{j_{d}}, z_{k_{d}}\right)
$$

and define a new open immersion

$$
\iota_{p}^{\prime}: \mathcal{U}_{p} \hookrightarrow \overbrace{\mathbb{C} \times \cdots \times \mathbb{C}}^{n \text { times }}=\overbrace{\mathbb{C}^{2} \times \cdots \times \mathbb{C}^{2}}^{d \text { times }}
$$

by this new coordinate system. By $\iota_{p}^{\prime}$, the topological $n$-cycle $S$ is identified locally at $p$ with

$$
(-1)^{k_{0}+1} \operatorname{sgn}\left(\sigma_{J}^{\prime}\right) W(\pi / m) \times \cdots \times W(\pi / m)
$$

where $\sigma_{J}^{\prime}$ is the permutation

$$
\left(\begin{array}{ccccccc}
1 & & \cdots & \hat{k_{0}} & \cdots & n & n+1 \\
j_{1} & k_{1} & \cdots & & \cdots & j_{d} & k_{d}
\end{array}\right) .
$$

On the other hand, $L_{J, \beta}$ is identified by $\iota_{p}^{\prime}$ with

$$
\Lambda_{\beta_{1}} \times \cdots \times \Lambda_{\beta_{d}}
$$

locally at $p$. By Lemma 3.3, we have

$$
\begin{equation*}
\left\langle L_{J, \beta}, S\right\rangle=(-1)^{k_{0}+1} \operatorname{sgn}\left(\sigma_{J}^{\prime}\right) s\left(\beta_{1}\right) \cdots s\left(\beta_{d}\right) \quad \text { if } \beta_{0}=\eta \tag{3.4}
\end{equation*}
$$

Suppose that $\beta_{0}=\eta^{-1}$. We calculate the local intersection number of $L_{J, \beta}$ and $S$ at $p:=\gamma_{k_{0}}^{-1}\left(p_{k_{0}}\right)$. As was shown above, the new open immersion $\iota_{p}^{\prime}$ identifies $S$ with

$$
-(-1)^{k_{0}+1} \operatorname{sgn}\left(\sigma_{J}^{\prime}\right) W(\pi / m) \times \cdots \times W(\pi / m)
$$

locally at $p$. Calculating as above, we have

$$
\begin{equation*}
\left\langle L_{J, \beta}, S\right\rangle=-(-1)^{k_{0}+1} \operatorname{sgn}\left(\sigma_{J}^{\prime}\right) s\left(\beta_{1}\right) \cdots s\left(\beta_{d}\right) \quad \text { if } \beta_{0}=\eta^{-1} . \tag{3.5}
\end{equation*}
$$

The dependence on $\beta_{0}$ in the right-hand sides of (3.2), (3.4), (3.5) can be expressed by the extra factor $s\left(\beta_{0}\right)$. Observing that $(-1)^{k_{0}+1} \operatorname{sgn}\left(\sigma_{J}^{\prime}\right)=\operatorname{sgn}\left(\sigma_{J}\right)$, we complete the proof of Theorem 2.2.

## 4. The $R$-submodule $\mathcal{L}_{\mathcal{K}}(X)$.

### 4.1. Preliminaries.

For an $R$-module $M$, we put $M^{\vee}:=\operatorname{Hom}_{\mathbb{Z}}(M, \mathbb{Z})$, which is regarded as an $R$-module via the contragredient action of $G$ on $M^{\vee}$.

Let $M$ be a finitely generated $\mathbb{Z}$-module. We put $d_{M}:=\operatorname{rank} M=\operatorname{dim}_{\mathbb{Q}} M \otimes \mathbb{Q}$. Note that $M$ is torsion free if and only if it can be generated by $d_{M}$ elements.

Lemma 4.1. Let $x_{1}, \ldots, x_{N}$ be variables. We put

$$
A:=\mathbb{Z}\left[x_{1}, \ldots, x_{N}\right] /\left(x_{1}^{m}-1, \ldots, x_{N}^{m}-1\right),
$$

and $\theta:=\left(x_{1}-1\right) \cdots\left(x_{N}-1\right)$. Then $A /(\theta)$ is torsion free as a $\mathbb{Z}$-module. Moreover the annihilator ideal of $\theta$ in $A$ is generated by $\phi\left(x_{1}\right), \ldots, \phi\left(x_{N}\right)$.

Proof. We fix the monomial order grevlex on $\mathbb{Z}\left[x_{1}, \ldots, x_{N}\right]$ (see [2, Chapter 2]). Since the leading coefficients of $x_{1}^{m}-1, \ldots, x_{N}^{m}-1$ and $\theta$ are 1 , the division algorithm by the set of these polynomials can be carried out over $\mathbb{Z}$. Then we see that $A /(\theta)$ is generated as a $\mathbb{Z}$-module by

$$
\begin{equation*}
x_{1}^{\nu_{1}} \cdots x_{N}^{\nu_{N}} \quad \text { with } 0 \leq \nu_{i}<m \text { for all } i \text { and } \nu_{i}=0 \text { for at least one } i . \tag{4.1}
\end{equation*}
$$

On the other hand, the reduced 0-dimensional scheme $\operatorname{Spec}(A /(\theta) \otimes \mathbb{C})$ consists of the closed points

$$
\begin{equation*}
\left(a_{1}, \ldots, a_{N}\right) \in \mu_{m}^{N} \quad \text { with } a_{i}=1 \text { for at least one } i \tag{4.2}
\end{equation*}
$$

The number of monomials in (4.1) is equal to the number of points in (4.2), and the latter is equal to $d_{A /(\theta)}$. Hence, by the observation above, we see that $A /(\theta)$ is torsion free. The second part also follows from the division algorithm over $\mathbb{Z}$ by $\left\{\phi\left(x_{1}\right), \ldots, \phi\left(x_{N}\right)\right\}$ of monic polynomials of degree $m-1$.

### 4.2. Proof of Part (a) of Theorem 1.1.

We define a non-degenerate symmetric bilinear form [, ]: $R \times R \rightarrow \mathbb{Z}$ by

$$
\left[t_{1}^{\nu_{1}} \cdots t_{n+1}^{\nu_{n+1}}, t_{1}^{\nu_{1}^{\prime}} \cdots t_{n+1}^{\nu_{n+1}^{\prime}}\right]:=\delta_{\nu_{1} \nu_{1}^{\prime}} \cdots \delta_{\nu_{n+1} \nu_{n+1}^{\prime}}
$$

where $\delta_{i j}$ is the Kronecker delta on $\mathbb{Z} / m \mathbb{Z}$. Since [, ] obviously is unimodular and satisfies $\left[g f, g f^{\prime}\right]=\left[f, f^{\prime}\right]$ for $f, f^{\prime} \in R$ and $g \in G$, it induces an isomorphism $R \cong R^{\vee}$ of $R$-modules. Note that the image of the dual homomorphism $f^{\vee}: M^{\vee} \rightarrow R$ of an $R$-linear
homomorphism $f: R \rightarrow M$ is an ideal of $R$, and the cokernel of $f^{\vee}$ is always torsion free, because

$$
\operatorname{Im} f^{\vee}=\{x \in R \mid[x, y]=0 \text { for any } y \in \operatorname{Ker} f\}
$$

In particular, the surjective homomorphism $R \rightarrow V_{n}(X)$ in Theorem 2.1 defines an ideal $V_{n}(X)^{\vee} \hookrightarrow R$ of $R$ such that $R / V_{n}(X)^{\vee}$ is torsion free as a $\mathbb{Z}$-module. On the other hand, the $G$-invariant intersection pairing $\langle$,$\rangle defines an isomorphism H_{n}(X) \cong$ $H_{n}(X)^{\vee}$ of $R$-modules. Hence we obtain the dual homomorphism $H_{n}(X) \rightarrow V_{n}(X)^{\vee}$ of $V_{n}(X) \hookrightarrow H_{n}(X)$, which is surjective because $V_{n}(X)$ is primitive in $H_{n}(X)$ (see (2.1)). By construction, the composite $H_{n}(X) \rightarrow R$ of the two homomorphisms $H_{n}(X) \rightarrow V_{n}(X)^{\vee}$ and $V_{n}(X)^{\vee} \hookrightarrow R$ maps $\tau \in H_{n}(X)$ to

$$
\sum_{\nu_{1}, \ldots, \nu_{n+1} \in \mathbb{Z} / m \mathbb{Z}}\left\langle\tau, \gamma_{1}^{\nu_{1}} \cdots \gamma_{n+1}^{\nu_{n+1}}(S)\right\rangle \cdot t_{1}^{\nu_{1}} \cdots t_{n+1}^{\nu_{n+1}} \in R
$$

Consider the composite

$$
\mathcal{L}_{\mathcal{K}}(X) \hookrightarrow H_{n}(X) \rightarrow V_{n}(X)^{\vee}
$$

where the second homomorphism is the dual of $V_{n}(X) \hookrightarrow H_{n}(X)$. Let $\mathcal{L}_{\mathcal{K}}^{\prime}(X)$ be the image of this composite. We have the following:

Claim 4.2. One has $\operatorname{rank} \mathcal{L}_{\mathcal{K}}(X)=\operatorname{rank} \mathcal{L}_{\mathcal{K}}^{\prime}(X)+1$, and

$$
H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X) \cong V_{n}(X)^{\vee} / \mathcal{L}_{\mathcal{K}}^{\prime}(X)
$$

Proof. Let $P_{X} \in H_{n}(X)$ denote the class of the intersection of $X$ and a $(d+1)$ dimensional subspace of $\mathbb{P}^{n+1}$. By the Lefschetz hyperplane section theorem, the kernel of $H_{n}(X) \rightarrow V_{n}(X)^{\vee}$ is $\mathbb{Z} P_{X}$. Therefore it is enough to show that $\mathcal{L}_{\mathcal{K}}(X)$ contains $P_{X}$. Since $\mathcal{K}$ is non-empty, we can assume by a permutation of coordinates that $J_{0}:=$ $[[0,1],[2,3], \ldots,[n, n+1]]$ is an element of $\mathcal{K}$. Consider the $(d+1)$-dimensional subspace of $\mathbb{P}^{n+1}$ defined by

$$
z_{2}-\eta z_{3}=z_{4}-\eta z_{5}=\cdots=z_{2 d}-\eta z_{2 d+1}=0
$$

Then its intersection with $X$ is defined in $\mathbb{P}^{n+1}$ by

$$
z_{0}^{m}+z_{1}^{m}=z_{2}-\eta z_{3}=z_{4}-\eta z_{5}=\cdots=z_{n}-\eta z_{n+1}=0
$$

which is the union of $m$ standard $d$-spaces $L_{\left[J_{0},\left(\eta \zeta^{\nu}, \eta, \ldots, \eta\right)\right]}$ for $\nu=0, \ldots, m-1$ in $X$. Thus we have $P_{X} \in \mathcal{L}_{\mathcal{K}}(X)$ and Claim 4.2 is proved.

Since $\mathcal{L}_{\mathcal{K}}^{\prime}(X)$ is an $R$-submodule of the ideal $V_{n}(X)^{\vee}$ of $R$ and $R / V_{n}(X)^{\vee}$ is torsion free, the torsion of $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X) \cong V_{n}(X)^{\vee} / \mathcal{L}_{\mathcal{K}}^{\prime}(X)$ is isomorphic to the torsion of $R / \mathcal{L}_{\mathcal{K}}^{\prime}(X)$. Therefore, in order to prove Part (a) of Theorem 1.1, it is enough to show
that the ideal $\mathcal{L}_{\mathcal{K}}^{\prime}(X)$ of $R$ is generated by the polynomials $\psi_{J}$, where $J$ runs through $\mathcal{K}$. For each $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{J}$, we let $G$ acts on the set $\mathcal{B}$ by

$$
\begin{equation*}
[g, J](\beta):=\left(\zeta^{-\nu_{k_{0}}} \beta_{0}, \zeta^{\nu_{j_{1}}-\nu_{k_{1}}} \beta_{1}, \ldots, \zeta^{\nu_{j_{d}}-\nu_{k_{d}}} \beta_{d}\right) \tag{4.3}
\end{equation*}
$$

Then we have

$$
g^{-1}\left(L_{J, \beta}\right)=L_{J,[g, J](\beta)} .
$$

Moreover, for any $\beta, \beta^{\prime} \in \mathcal{B}$ and $J \in \mathcal{J}$, there exists $g \in G$ such that $\beta^{\prime}=[g, J](\beta)$. Hence, for a fixed $J \in \mathcal{J}$, the $\mathbb{Z}$-submodule $\mathcal{L}_{\{J\}}(X)$ of $H_{n}(X)$ generated by the classes $\left[L_{J, \beta}\right]$ of $L_{J, \beta}(\beta \in \mathcal{B})$ is the $R$-submodule generated by a single element $\left[L_{J,(\eta, \ldots, \eta)}\right]$. It is therefore enough to show that the image $\psi_{J}^{\prime}$ of $\left[L_{J,(\eta, \ldots, \eta)}\right]$ by the homomorphism $\mathcal{L}_{\mathcal{K}}(X) \hookrightarrow H_{n}(X) \rightarrow V_{n}(X)^{\vee} \hookrightarrow R$ is equal to $\psi_{J}$ up to sign.

Suppose that

$$
\psi_{J}^{\prime}=\sum a_{\nu_{1} \ldots \nu_{n+1}} t_{1}^{\nu_{1}} \cdots t_{n+1}^{\nu_{n+1}}
$$

where the summation is taken over all $(n+1)$-tuples $\left(\nu_{1}, \ldots, \nu_{n+1}\right) \in(\mathbb{Z} / m \mathbb{Z})^{n+1}$, and $a_{\nu_{1} \ldots \nu_{n+1}} \in \mathbb{Z}$. For simplicity, we put

$$
e(\nu):=s\left(\zeta^{-\nu} \eta\right)= \begin{cases}1 & \text { if } \nu=0 \\ -1 & \text { if } \nu=1 \\ 0 & \text { otherwise }\end{cases}
$$

Then, writing $\gamma_{1}^{\nu_{1}} \cdots \gamma_{n+1}^{\nu_{n+1}}$ by $g$, we have

$$
\begin{aligned}
a_{\nu_{1} \ldots \nu_{n+1}} & =\left\langle L_{J,(\eta, \ldots, \eta)}, g(S)\right\rangle \\
& =\left\langle g^{-1}\left(L_{J,(\eta, \ldots, \eta)}\right), S\right\rangle \\
& =\left\langle L_{J,[g, J](\eta, \ldots, \eta)}, S\right\rangle \\
& =\operatorname{sgn}\left(\sigma_{J}\right) e\left(\nu_{k_{0}}\right) e\left(\nu_{k_{1}}-\nu_{j_{1}}\right) \cdots e\left(\nu_{k_{d}}-\nu_{j_{d}}\right),
\end{aligned}
$$

where the last equality follows from Theorem 2.2. It remains to notice that

$$
\sum_{\nu \in \mathbb{Z} / m \mathbb{Z}} e(\nu) t^{\nu}=1-t \quad \text { and } \quad \sum_{\nu, \nu^{\prime} \in \mathbb{Z} / m \mathbb{Z}} e\left(\nu-\nu^{\prime}\right) t_{1}^{\nu} t_{2}^{\nu^{\prime}}=\left(1-t_{1}\right) \phi\left(t_{1} t_{2}\right) .
$$

Therefore we do have $\psi_{J}^{\prime}= \pm \psi_{J}$.

### 4.3. Proof of Theorem 1.4 and Corollary 1.5.

We put

$$
A_{\mathcal{K}}:=R /\left(\psi_{J} \mid J \in \mathcal{K}\right) .
$$

Let $K_{p}$ be an algebraically closed field of characteristic $p \geq 0$. Since

$$
\operatorname{dim}_{K_{p}}\left(R \otimes K_{p}\right)=m^{n+1}
$$

does not depend on $p$, the $\mathbb{Z}$-module $A_{\mathcal{K}}$ has a torsion element of order $p$ if and only if

$$
\operatorname{dim}_{K_{p}}\left(A_{\mathcal{K}} \otimes K_{p}\right)>\operatorname{dim}_{\mathbb{C}}\left(A_{\mathcal{K}} \otimes \mathbb{C}\right)
$$

On the other hand, by Claim 4.2 and $\mathcal{L}_{\mathcal{K}}^{\prime}(X)=\left(\psi_{J} \mid J \in \mathcal{K}\right)$ in $R$, we have

$$
\operatorname{rank} \mathcal{L}_{\mathcal{K}}(X)=m^{n+1}-\operatorname{dim}_{\mathbb{C}}\left(A_{\mathcal{K}} \otimes \mathbb{C}\right)+1
$$

Therefore it is enough to prove the following:
Claim 4.3. If $p=0$ or $(p, m)=1$, then

$$
\operatorname{dim}_{K_{p}}\left(A_{\mathcal{K}} \otimes K_{p}\right)=m^{n+1}-\left|\Gamma_{\mathcal{K}}\right|
$$

Thus, from now on we assume that $p=0$ or $(p, m)=1$. Then $R \otimes K_{p}$ is a semisimple ring, and all its simple modules have dimension one over $K_{p}$ : they correspond to the multi-eigenvalues of $\left(t_{1}, \ldots, t_{n+1}\right)$, which are all $m$-th roots of unity (cf. Definition 1.3 in the case $K_{p}=\mathbb{C}$ ). In other words,

$$
M:=\operatorname{Spec}\left(R \otimes K_{p}\right)
$$

is a reduced scheme of dimension zero consisting of $m^{n+1}$ closed points. Then the scheme $\operatorname{Spec}\left(A_{\mathcal{K}} \otimes K_{p}\right)$ is a closed subscheme $M_{\mathcal{K}}$ of $M$, and $\operatorname{dim}_{K_{p}}\left(A_{\mathcal{K}} \otimes K_{p}\right)$ is the number of closed points of $M_{\mathcal{K}}$. Let $\Gamma_{\mathcal{K}}$ be the subset of $M$ defined by Definition 1.3 with $\mathbb{C}$ replaced by $K_{p}$. Note that, for $a \in K_{p}^{\times}$with $a^{m}=1$, we have

$$
\phi(a)=0 \Longleftrightarrow a \neq 1
$$

Therefore, for $P=\left(a_{1}, \ldots, a_{n+1}\right) \in M$, we have

$$
\begin{aligned}
P \notin M_{\mathcal{K}} \Longleftrightarrow & \psi_{J}\left(a_{1}, \ldots, a_{n+1}\right) \neq 0 \text { for some } J \in \mathcal{K} \\
\Longleftrightarrow & a_{k_{0}} \neq 1, \ldots, a_{k_{d}} \neq 1 \text { and } a_{j_{1}} a_{k_{1}}=\cdots=a_{j_{d}} a_{k_{d}}=1 \\
& \text { for some } J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{K} \\
\Longleftrightarrow & a_{i} \neq 1 \text { for } i=1, \ldots, n+1 \text { and } a_{j_{1}} a_{k_{1}}=\cdots=a_{j_{d}} a_{k_{d}}=1 \\
& \text { for some } J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{K} \\
\Longleftrightarrow & P \in \Gamma_{\mathcal{K}} .
\end{aligned}
$$

Therefore we have $\operatorname{dim}_{K_{p}}\left(A_{\mathcal{K}} \otimes K_{p}\right)=\left|M_{\mathcal{K}}\right|=|M|-\left|\Gamma_{\mathcal{K}}\right|$. This concludes the proof of Claim 4.3 and, hence, that of Theorem 1.4 and Corollary 1.5.

Remark 4.4. The rank of $\mathcal{L}(X)=\mathcal{L}_{\mathcal{J}}(X)=1+\left|\Gamma_{\mathcal{J}}\right|$ is equal to the constant term of the expansion of

$$
\begin{cases}1+\left(x_{1}+\cdots+x_{h-1}+1+x_{h-1}^{-1}+\cdots+x_{1}^{-1}\right)^{n+2} & \text { if } m=2 h \text { is even } \\ 1+\left(x_{1}+\cdots+x_{h}+x_{h}^{-1}+\cdots+x_{1}^{-1}\right)^{n+2} & \text { if } m=2 h+1 \text { is odd. }\end{cases}
$$

For small dimensions $n$, we have

$$
\operatorname{rank} \mathcal{L}(X)= \begin{cases}3 m^{2}-9 m+6+\delta_{m} & \text { for } n=2 \\ 15 m^{3}-90 m^{2}+175 m-100+(15 m-39) \delta_{m} & \text { for } n=4 \\ 105 m^{4}-1050 m^{3}+3955 m^{2}-6335 m+3325 \\ +\left(210 m^{2}-1302 m+2010\right) \delta_{m} & \text { for } n=6\end{cases}
$$

where $\delta_{m} \in\{0,1\}$ satisfies $\delta_{m} \equiv m-1 \bmod 2$.

### 4.4. Proof of Part (b) of Theorem 1.1.

The following lemma is immediate:
Lemma 4.5. In $\mathbb{Z}[x, y] /\left(x^{m}-1, y^{m}-1\right)$, we have

$$
(y-1) \phi(x y)=-(x-1)(y-1) \rho(x, y) .
$$

We put

$$
\lambda:=\left(t_{1}-1\right) \cdots\left(t_{n+1}-1\right) .
$$

By Lemma 4.5, we have

$$
\psi_{J}:= \pm \lambda \rho_{J} .
$$

Hence $R /\left(\psi_{J} \mid J \in \mathcal{K}\right)$ in Part (a) of Theorem 1.1 is equal to $R /\left(\lambda \rho_{J} \mid J \in \mathcal{K}\right)$. Consider the natural exact sequence

$$
0 \rightarrow(\lambda) /\left(\lambda \rho_{J} \mid J \in \mathcal{K}\right) \rightarrow R /\left(\lambda \rho_{J} \mid J \in \mathcal{K}\right) \rightarrow R /(\lambda) \rightarrow 0
$$

Since $R /(\lambda)$ is a free $\mathbb{Z}$-module by Lemma 4.1, the torsion of $R /\left(\psi_{J} \mid J \in \mathcal{K}\right)$ is isomorphic to the torsion of $(\lambda) /\left(\lambda \rho_{J} \mid J \in \mathcal{K}\right)$. The homomorphism $R \rightarrow(\lambda)$ given by $f \mapsto$ $f \lambda$ identifies $(\lambda)$ with $\bar{R}$ by Lemma 4.1, and under this identification, the submodule $\left(\lambda \rho_{J} \mid J \in \mathcal{K}\right)$ of $(\lambda)$ coincides with the ideal $\left(\rho_{J} \mid J \in \mathcal{K}\right)$ of $\bar{R}$. Therefore we have $(\lambda) /\left(\lambda \rho_{J} \mid J \in \mathcal{K}\right) \cong \bar{R} /\left(\rho_{J} \mid J \in \mathcal{K}\right)$.

### 4.5. Proof of Parts (c) and (d) of Theorem 1.1.

Part (c) and Part (d) are dual to Part (a) and Part (b), respectively. We use the following simple observation. Let $\varphi: M_{1} \rightarrow M_{2}$ be a homomorphism of free $\mathbb{Z}$-modules, and let $\varphi^{\vee}: M_{2}^{\vee} \rightarrow M_{1}^{\vee}$ be the dual of $\varphi$. Then there exist canonical isomorphisms

$$
\operatorname{Tors} \operatorname{Coker}(\varphi)=\operatorname{Ext}_{\mathbb{Z}}\left(\operatorname{Tors} \operatorname{Coker}\left(\varphi^{\vee}\right), \mathbb{Z}\right)=\operatorname{Hom}_{\mathbb{Z}}\left(\operatorname{Tors} \operatorname{Coker}\left(\varphi^{\vee}\right), \mathbb{Q} / \mathbb{Z}\right)
$$

where Tors $M$ denotes the torsion of a $\mathbb{Z}$-module $M$. Hence, there also exists a noncanonical isomorphism $\operatorname{Tors} \operatorname{Coker}(\varphi) \cong \operatorname{Tors} \operatorname{Coker}\left(\varphi^{\vee}\right)$.

We put

$$
L_{\mathcal{K}}:=\bigcup_{J \in \mathcal{K}, \beta \in \mathcal{B}} L_{J, \beta},
$$

and consider the groups

$$
H_{n}\left(L_{\mathcal{K}}\right)=\bigoplus_{J \in \mathcal{K}, \beta \in \mathcal{B}} \mathbb{Z}\left[L_{J, \beta}\right], \quad H^{n}\left(L_{\mathcal{K}}\right)=\bigoplus_{J \in \mathcal{K}, \beta \in \mathcal{B}} \mathbb{Z}\left[L_{J, \beta}\right]^{\vee}
$$

each of which has a natural structure of the $R$-modules (see (4.3)). The inclusion $L_{\mathcal{K}} \hookrightarrow X$ induces an $R$-linear homomorphism

$$
\varphi: H_{n}\left(L_{\mathcal{K}}\right) \rightarrow H_{n}(X)
$$

Then $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X)=\operatorname{Coker}(\varphi)$. Note that $\langle$,$\rangle defines an isomorphism H_{n}(X) \cong$ $H_{n}(X)^{\vee}$ (the Poincaré duality), and hence we obtain the dual homomorphism

$$
\varphi^{\vee}: H_{n}(X) \rightarrow H^{n}\left(L_{\mathcal{K}}\right)
$$

By the observation above, the torsion in question is the dual of the torsion of $\operatorname{Coker}\left(\varphi^{\vee}\right)$, and hence these torsions are isomorphic. Consider the composite

$$
\varphi_{V}^{\vee}: R \rightarrow V_{n}(X) \hookrightarrow H_{n}(X) \rightarrow H^{n}\left(L_{\mathcal{K}}\right)
$$

where the first surjection is given by Theorem 2.1. Since $V_{n}(X)$ is primitive in $H_{n}(X)$ (see (2.1)), the torsion of $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X)$ is isomorphic to the torsion of $\operatorname{Coker}\left(\varphi_{V}^{\vee}\right)$. Recall that we regard $H^{n}\left(L_{\mathcal{K}}\right)$ as an $R$-module via

$$
g\left(\left[L_{J, \beta}\right]^{\vee}\right)=\left[L_{J,\left[g^{-1}, J\right] \beta}\right]^{\vee} .
$$

For $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{K}$, the natural homomorphism

$$
\begin{equation*}
R \rightarrow R\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee}=\bigoplus_{\beta \in \mathcal{B}} \mathbb{Z}\left[L_{J, \beta}\right]^{\vee} \tag{4.4}
\end{equation*}
$$

given by $1 \mapsto\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee}$ identifies $R\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee}$ with

$$
\begin{equation*}
R_{J}=R /\left(t_{j_{1}} t_{k_{1}}-1, \ldots, t_{j_{d}} t_{k_{d}}-1\right)=\mathbb{Z}\left[t_{k_{0}}, \ldots, t_{k_{d}}\right] /\left(t_{k_{0}}^{m}-1, \ldots, t_{k_{d}}^{m}-1\right), \tag{4.5}
\end{equation*}
$$

where the second equality follows from the relations $t_{j_{\nu}}=t_{k_{\nu}}^{m-1}(\nu=1, \ldots, d)$ in $R_{J}$.

Indeed, each $t_{j_{i}} t_{k_{i}}-1$ is contained in the kernel of (4.4) by the definition (4.3) of the action of $G$, and both $\mathbb{Z}$-modules $R_{J}$ and $R\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee}$ are free of rank $m^{d+1}=|\mathcal{B}|$. Hence we have

$$
H^{n}\left(L_{\mathcal{K}}\right)=\bigoplus_{J \in \mathcal{K}} R_{J}
$$

The homomorphism $\varphi_{V}^{\vee}$ is given by

$$
1 \mapsto \sum_{J \in \mathcal{K}} \sum_{\beta \in \mathcal{B}}\left\langle S, L_{J, \beta}\right\rangle\left[L_{J, \beta}\right]^{\vee} .
$$

For $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{K}$, we have

$$
\left[\left(\gamma_{k_{0}}^{-\alpha_{0}} \cdots \gamma_{k_{d}}^{-\alpha_{d}}\right)^{-1}, J\right](\eta, \ldots, \eta)=\left(\zeta^{-\alpha_{0}} \eta, \ldots, \zeta^{-\alpha_{d}} \eta\right)
$$

and hence, by Theorem 2.2, we obtain

$$
\begin{aligned}
& \sum_{\beta \in \mathcal{B}}\left\langle S, L_{J, \beta}\right\rangle\left[L_{J, \beta}\right]^{\vee} \\
& \quad=\operatorname{sgn}\left(\sigma_{J}\right) \sum_{\alpha_{0} \in \mathbb{Z} / m \mathbb{Z}} \cdots \sum_{\alpha_{d} \in \mathbb{Z} / m \mathbb{Z}} e\left(\alpha_{0}\right) \cdots e\left(\alpha_{d}\right)\left[L_{J,\left(\zeta^{-\alpha_{0}} \eta, \ldots, \zeta^{-\alpha_{d}} \eta\right)}\right]^{\vee} \\
& \quad=\operatorname{sgn}\left(\sigma_{J}\right) \sum_{\alpha_{0}=0}^{1} \cdots \sum_{\alpha_{d}=0}^{1} e\left(\alpha_{0}\right) \cdots e\left(\alpha_{d}\right) \gamma_{k_{0}}^{-\alpha_{0}} \cdots \gamma_{k_{d}}^{-\alpha_{d}}\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee} \\
& \quad=\operatorname{sgn}\left(\sigma_{J}\right)\left(1-t_{k_{0}}^{-1}\right) \cdots\left(1-t_{k_{d}}^{-1}\right)\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee} \\
& \quad=\operatorname{sgn}\left(\sigma_{J}\right)\left(t_{k_{0}}-1\right) \cdots\left(t_{k_{d}}-1\right) t_{k_{0}}^{-1} \cdots t_{k_{d}}^{-1}\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee} \\
& \quad=\tau_{J} c_{J}
\end{aligned}
$$

where $c_{J}:=\operatorname{sgn}\left(\sigma_{J}\right) t_{k_{0}}^{-1} \cdots t_{k_{d}}^{-1}\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee}$. Note that $\operatorname{sgn}\left(\sigma_{J}\right) t_{k_{0}}^{-1} \cdots t_{k_{d}}^{-1}$ is a unit in $R_{J}$. Replacing the generator $\left[L_{J,(\eta, \ldots, \eta)}\right]^{\vee}$ of each factor of $H^{n}\left(\mathcal{L}_{\mathcal{K}}\right)=\bigoplus_{J \in \mathcal{K}} R_{J}$ by $c_{J}$, the image of $\varphi_{V}^{\vee}$ is the $R$-submodule $\mathcal{M}$ generated by

$$
s:=\sum_{J \in \mathcal{K}} \tau_{J} 1_{J} .
$$

Thus Part (c) is proved.
For $J=\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{d}, k_{d}\right]\right] \in \mathcal{K}$, let $\left(\tau_{J}\right)$ be the ideal of $R_{J}$ generated by $\tau_{J}$. Then $s \in L_{\mathcal{K}}^{\vee}=\bigoplus_{J \in \mathcal{K}} R_{J}$ is contained in $\bigoplus_{J \in \mathcal{K}}\left(\tau_{J}\right)$. We consider the exact sequence

$$
0 \rightarrow\left(\bigoplus_{J \in \mathcal{K}}\left(\tau_{J}\right)\right) / R s \rightarrow\left(\bigoplus_{J \in \mathcal{K}} R_{J}\right) / R s \rightarrow \bigoplus_{J \in \mathcal{K}}\left(R_{J} /\left(\tau_{J}\right)\right) \rightarrow 0
$$

Since

$$
R_{J} /\left(\tau_{J}\right)=\mathbb{Z}\left[t_{k_{0}}, \ldots, t_{k_{d}}\right] /\left(t_{k_{0}}^{m}-1, \ldots, t_{k_{d}}^{m}-1, \tau_{J}\right)
$$

is a free $\mathbb{Z}$-module by the second equality of (4.5) and Lemma 4.1, the torsion of $\bigoplus_{J \in \mathcal{K}} R_{J} / R s$ is isomorphic to the torsion of $\bigoplus_{J \in \mathcal{K}}\left(\tau_{J}\right) / R s$. On the other hand, the homomorphism $R_{J} \rightarrow\left(\tau_{J}\right)$ given by $f \mapsto f \tau_{J}$ identifies $\left(\tau_{J}\right)$ with

$$
\bar{R}_{J}=\mathbb{Z}\left[t_{k_{0}}, \ldots, t_{k_{d}}\right] /\left(\phi\left(t_{k_{0}}\right), \ldots, \phi\left(t_{k_{d}}\right)\right)
$$

by Lemma 4.1, and under this identification, the element $\tau_{J} \in\left(\tau_{J}\right)$ corresponds to the multiplicative unit $1_{J}$ of $\bar{R}_{J}$. Therefore, by $\bigoplus_{J \in \mathcal{K}}\left(\tau_{J}\right) \cong \bigoplus_{J \in \mathcal{K}} \bar{R}_{J}$, the element $s \in$ $\bigoplus_{J \in \mathcal{K}} R_{J}$ corresponds to $\sum_{J \in \mathcal{K}} 1_{J} \in \bigoplus_{J \in \mathcal{K}} \bar{R}_{J}$. Hence $\left(\bigoplus_{J \in \mathcal{K}}\left(\tau_{J}\right)\right) / R s$ is isomorphic to $\left(\bigoplus_{J \in \mathcal{K}} \bar{R}_{J}\right) / \overline{\mathcal{M}}$.

### 4.6. Proof of Corollaries 1.6 and 1.7.

To prove Corollary 1.6 , we merely put $J_{0}:=[[0,1],[2,3], \ldots,[n, n+1]]$, and apply Part (d) of Theorem 1.1 to the case $\mathcal{K}=\left\{J_{0}\right\}$. We immediately see that $\mathcal{L}_{\left\{J_{0}\right\}}(X)$ is primitive in $H_{n}(X)$. Let $\mathcal{W}=\left\{W_{t}\right\}_{t \in U}$ be the family of smooth hypersurfaces defined by the equations of the form (1.3). The parameter space $U$ of this family is connected, and hence there exists a path $\gamma:[0,1] \rightarrow U$ from the Fermat variety $X=W_{\gamma(0)}$ to an arbitrary member $W=W_{\gamma(1)}$ of $\mathcal{W}$. Along the family $W_{\gamma(t)}$, the subspaces $L_{J_{0}, \beta}(\beta \in \mathcal{B})$ in $X$ deform to subspaces of $W_{\gamma(t)}$ defined by equations of the form

$$
\beta_{\nu}^{(i)}(t) z_{2 i}=\alpha_{\nu}^{(i)}(t) z_{2 i+1} \quad(i=0, \ldots, d, \quad \nu=1, \ldots, m) .
$$

Thus, along the constant (with respect to the Gauss-Manin connection) family $H_{n}\left(W_{\gamma(t)}\right)$ of $\mathbb{Z}$-modules over $\gamma$, the submodule $\mathcal{L}_{\left\{J_{0}\right\}}(X)$ of $H_{n}(X)$ is transported to the submodule of $H_{n}(W)$ generated by the classes $\left[L_{\left(\nu_{0}, \ldots, \nu_{d}\right)}^{\prime}\right]$ of subspaces $L_{\left(\nu_{0}, \ldots, \nu_{d}\right)}^{\prime}$ in $W$. The rank and the primitivity are preserved during the transport.

For Corollary 1.7, we use the same continuity argument, deforming $W_{s}$ to the Fermat variety and representing the submodule in question as $\mathcal{L}_{\mathcal{J}_{s}}(X)$, where $\mathcal{J}_{s}$ is the set of all partitions "identical beyond $s$ ", i.e., those of the form

$$
\left[\left[j_{0}, k_{0}\right], \ldots,\left[j_{s}, k_{s}\right],[2 s+2,2 s+3], \ldots,[n, n+1]\right], \quad 0 \leq j_{i}, k_{i} \leq 2 s+1
$$

The restriction of $\mathcal{J}_{s}$ to the index set $\overline{2 s+1}$ is well-defined and coincides with the full set $\mathcal{J}(2 s)$ of partitions of $\overline{2 s+1}$. Then, denoting by (•) the dependence on the dimension (or the number of variables in the polynomial rings), it is easy to see that the module $\overline{\mathcal{C}}_{\mathcal{J}_{s}}(2 d)$ given by Part (d) of Theorem 1.1 can be represented in the form

$$
\overline{\mathcal{C}}_{\mathcal{J}_{s}}(2 d)=\overline{\mathcal{C}}_{\mathcal{J}(2 s)}(2 s) \otimes_{\mathbb{Z}} \bar{S}(s, d),
$$

where

$$
\bar{S}(s, d):=\mathbb{Z}\left[t_{2 s+2}, t_{2 s+4}, \ldots, t_{2 d}\right] /\left(\phi\left(t_{2 s+2}\right), \phi\left(t_{2 s+4}\right), \ldots, \phi\left(t_{2 d}\right)\right) .
$$

(Since the tail of each partition is fixed, we have the "constant" relations

$$
t_{2 s+2} t_{2 s+3}=\cdots=t_{2 d} t_{2 d+1}=1
$$

hence, we can retain the even index variables only and take these variables out.) Thus, this module is free (as an abelian group) if and only if so is $\overline{\mathcal{C}}_{\mathcal{J}(2 s)}(2 s)$, i.e., if and only if Conjecture 1.2 holds for Fermat varieties of dimension $2 s$ in $\mathbb{P}^{2 s+1}$.

For the last assertion of Corollary 1.7, we observe that Conjecture 1.2 does hold for the Fermat varieties of dimension 0 (obvious) and 2 (see [3]).

## 5. Computational criterion.

In this section, we focus on the description of the torsion of $H_{n}(X) / \mathcal{L}_{\mathcal{K}}(X)$ given by Part (b) of Theorem 1.1. We put

$$
B_{\mathcal{K}}:=\bar{R} /\left(\rho_{J} \mid J \in \mathcal{K}\right)
$$

By Lemma 4.5, the ideal $\left(\rho_{J} \mid J \in \mathcal{K}\right)$ defines the closed subscheme $\Gamma_{\mathcal{K}}$ in the reduced 0 -dimensional scheme $\operatorname{Spec}(\bar{R} \otimes \mathbb{C})=\left(\mu_{m} \backslash\{1\}\right)^{n+1}$, and hence we can calculate $d_{0}:=$ $\operatorname{dim}_{\mathbb{C}}\left(B_{\mathcal{K}} \otimes \mathbb{C}\right)=\left|\Gamma_{\mathcal{K}}\right|$. On the other hand, for each prime divisor $p$ of $m$, we can calculate $d_{p}:=\operatorname{dim}_{\mathbb{F}_{p}}\left(B_{\mathcal{K}} \otimes \mathbb{F}_{p}\right)$ by calculating a Gröbner basis of the ideal

$$
\begin{equation*}
\left(\phi\left(t_{1}\right), \ldots, \phi\left(t_{n+1}\right)\right)+\left(\rho_{J} \mid J \in \mathcal{K}\right) \tag{5.1}
\end{equation*}
$$

in the polynomial ring $\mathbb{F}_{p}\left[t_{1}, \ldots, t_{n+1}\right]$. By Corollary 1.5 , we see that $\mathcal{L}_{\mathcal{K}}(X)$ is primitive in $H_{n}(X)$ if and only if $d_{0}=d_{p}$ holds for any prime divisor $p$ of $m$.

Using this method, we have confirmed the primitivity of $\mathcal{L}(X)=\mathcal{L}_{\mathcal{J}}(X)$ in $H_{n}(X)$ by the computer-aided calculation in the following cases:

$$
(n, m)=(4, m) \text { where } 3 \leq m \leq 12, \quad(6,3),(6,4),(6,5),(8,3)
$$
