TOWARD A THEORY OF GENERALIZED COHEN-MACAULAY MODULES

NGÔ VIÊT TRUNG

Introduction

Throughout this paper, A denotes a noetherian local ring with maximal ideal m and M a finitely generated A-module with $d:=\dim M \ge 1$.

DEFINITION. M is called a generalized Cohen-Macaulay (abbr. C-M) module if

 $l(H^i_{\mathfrak{m}}(M)) < \infty$

for $i = 0, \dots, d - 1$, where *l* denotes the length and $H^i_{\mathfrak{m}}(M)$ the *i*th local cohomology module of *M* with respect to \mathfrak{m} .

The notion of generalized C-M modules was introduced in [6]. It has its roots in a problem of D.A. Buchsbaum. Roughly speaking, this problem says that the difference

$$I(\mathfrak{q}; M) := l(M/\mathfrak{q}M) - e(\mathfrak{q}; M)$$

takes a constant value for all parameter ideals q of M, where e(q; M) denotes the multiplicity of M relative to q [5]. In general, that is not true [30]. However, J. Stückrad and W. Vogel found that modules satisfying this problem enjoy many interesting properties which are similar to the ones of C-M modules and gave them the name Buchsbaum modules [22], [23]. That led in [6] to the study of modules M with the property

$$I(M) := \sup I(\mathfrak{q};M) < \infty$$

where q runs through all parameter ideals of M, and it turned out that they are just generalized C-M modules.

The class of generalized C-M module is rather large. For instance, most of the considered geometric local rings such as the ones of isolated singularities or of the vertices of affine cones over projective curves are

Received February 15, 1983.

generalized C-M rings. So it would be of interest to establish a theory of generalized C-M modules.

Although the theory of Buchsbaum modules has been rapidly developed by works of S. Goto, P. Schenzel, J. Stückrad, W. Vogel (see the monograph [20], little is known about generalized C-M modules. Besides, it lacks something which connects both kinds of modules together. If one is acquainted enough with the few references on generalized C-M modules [6], [11], [18], one might have the notice that almost all properties of systems of parameters (abbr. s.o.p.'s) of Buchsbaum modules also hold for s.o.p.'s of generalized C-M modules which are contained in a large power of the maximal ideal. For instance, if M is a generalized C-M module, there exists a positive integer n such that

$$I(\mathfrak{q}; M) = I(M)$$

for all parameter ideals $q \subseteq m^n$ of M. So, with regard to the origin of generalized C-M modules, one should try to explain the above phenomenon in studying s.o.p.'s a_1, \dots, a_a of M with the property

$$I(a_1, \cdots, a_d; M) = I(M).$$

Such s.o.p.'s will be called standard.

The aim of this paper is to show that standard s.o.p.'s carry important informations on the structure of generalized C-M modules and that via this notion, one can derive the theory of Buchsbaum modules from the theory of generalized C-M modules.

Now we will describe the organization of this paper together with its main results. The paper is divided in 6 sections.

In Section 1 we recall some basic facts on generalized C-M modules which will be used in the sequence.

In Section 2 we establish the main properties of standard s.o.p.'s. First, we can define standard s.o.p.'s of M very simply without assuming before that M is a generalized C-M module. Consequently, we get a surprising criterion stating that M is a generalized C-M module iff M has a standard s.o.p. of this sense (Theorem 2.1). We can also characterize standard s.o.p.'s by means of local cohomology (Theorem 2.5). From this it follows that they are standard sequences in the sense of M. Brodmann [3], [4], and special d-sequences in the sense of C. Huneke [14], [15]. It should be mentioned that d-sequences enjoy many interesting properties

and have been proved as very useful for different topics of Commutative Algebra, see [13], [27], [29].

In Section 3 we study ideals of A which have the property that every s.o.p. of M contained in them are standard. Such ideals will be called M-standard. M being a Buchsbaum module just means that m is Mstandard. There are various characterizations of standard ideals (Propositions 3.1, 3.2, Theorems 3.4, 3.10) which not only recover all known characterizations of Buchsbaum modules but yield new ones too.

In Section 4 we use standard s.o.p.'s to study Hilbert-Samuel (abbr. H-S) functions. First, inspired of the characterization of *d*-sequences by means of their H-S functions [27], we give a polynomial bounding above the H-S function of an arbitrary s.o.p. of a generalized C-M module M and show that they coincide iff this s.o.p. is standard (Theorem 4.1). Similarly, we can also estimate the H-S function of a submodule N of M of finite colength relative to an ideal α of A with $l(M|\alpha M) < \infty$ (Proposition 4.4). In particular, M and N will behave very well if $l(M|\alpha N)$ attains some extreme value (Proposition 4.8). As a consequence, we are able to extend results of J. Sally [17] and S. Goto [8] on C-M and Buchsbaum rings with maximal embedding dimension for modules.

In Section 5 we show that if α is a standard parameter ideal of M or if $l(M/\alpha^2 M)$ attains some extreme value (the module-version of Buchsbaum rings with maximal embedding dimension), then the associated graded module

$$G_{\mathfrak{a}}(M) := \bigoplus_{n=0}^{\infty} \mathfrak{a}^n M / \mathfrak{a}^{n+1} M$$

is a homogeneous generalized C-M module and its local cohomology modules can be computed explicitly (Theorem 5.4 and Proposition 5.11). Moreover, we give a necessary and sufficient condition for an irrelevant ideal of $G_q(A)$, where q is a parameter ideal of M, to be $G_q(M)$ -standard (Theorem 5.7). Applying these results to Buchsbaum modules, we then get the main results of S. Goto in [8] and [9].

In Section 6 we shall first see that there is a close connection between $G_{a}(M)$ and the Rees module

$$R_{\mathfrak{a}}(M) := \mathop{\oplus}\limits_{n=0}^{\infty} \mathfrak{a}^n M$$

concerning the property of being a generalized C-M module (Proposition 6.1). If α is a standard parameter ideal of M or if $l(M/\alpha^2 M)$ attains some

extreme value, then $[R_{a}(M)]_{q}$ is a generalized C-M module, where Q denotes the maximal graded ideal of $R_{a}(M)$, and its local cohomology modules can be computed explicitly (Theorem 6.2 and Proposition 6.5). As a consequence, we get necessary and sufficient conditions for $R_{a}(M)$ to be a Cohen-Macaulay module in these cases, generalizing recent results of S. Goto, Y. Shimoda, and P. Schenzel on this topic [7], [12], and [19].

It should be mentioned that special cases of Theorem 5.4, Proposition 5.11, and Theorem 6.2 are also obtained by M. Brodmann [4] and P. Schenzel (private communication).

Beside the notations introduced before, we shall use the following throughout this paper. Unless otherwise specified, a_1, \dots, a_d will be a s.o.p. of M. For convenience, we put

$$egin{aligned} \mathfrak{q}_0 &= 0 \quad (ext{the zeroideal}) \ \mathfrak{q}_i &= (a_1,\,\cdots,\,a_i) \quad (i=1,\,\cdots,\,d-1) \ \mathfrak{q}_d &= (a_1,\,\cdots,\,a_d). \end{aligned}$$

Moreover, we shall identify $H^0_{\mathfrak{m}}(M)$ with the submodule $\bigcup_{n=1}^{\infty} 0_M : \mathfrak{m}^n$ of M and denote by \overline{M} the factor module $M/H^0_{\mathfrak{m}}(M)$.

ACKNOWLEDGEMENT. This paper was written while the author supported by a grant of the Matumae International Foundation was visiting the Department of Mathematics of Nagoya University. He would like to express his sincere thanks to both institutions and to Professor H. Matsumura whose effort had made this visit possible. Compared with the first manuscript prepared before this visit, the present paper contains many improvements inspired by discussions with some Japanese mathematicians. The author is grateful to all of them, especially to S. Goto, S. Ikeda, and K. Yamagishi.

When the preparation of this paper was finished, the author learn that standard s.o.p.'s were also investigated by P. Schenzel in the preprints "Standard systems of parameters and their blowing-up rings" and "Extremal ideals and their form rings" but not in the complexity of the present paper. Especially, the theory of standard sequences has been further developed by Brodmann's papers "Local cohomology of certain Rees- and form-rings I, II" which contain, for example, results more general than Theorem 5.4 and Theorem 6.2.

Finally, the author would like to thank the referee for pointing out many mistakes of the manuscript.

§1. Basic facts

First, generalized C-M modules may be characterized in different ways.

LEMMA 1. [6, (3.3)]. The following conditions are equivalent:

(i) M is a generalized C-M module.

- (ii) $I(M) < \infty$
- (iii) There exists a s.o.p. a_1, \dots, a_d of M such that

 $\sup I(a_1^{n_1},\,\cdots,\,a_d^{n_d};\,M)<\infty$

where n_1, \dots, n_d run through all positive integers. (iv) There exists a positive integer n such that

$$\mathfrak{q}_{i-1}M$$
: $a_i \subseteq \mathfrak{q}_{i-1}M$: \mathfrak{m}^n

for every s.o.p. a_1, \dots, a_d of M and $i = 1, \dots, d$.

The meaning of Lemma 1.1 (ii) has been already mentioned in the introduction of this paper. Lemma 1.1 (iii) is used to check whether a given module is a generalized C-M module or not. To explain the meaning of Lemma 1.1 (iv) we need the following notion of [6, (2.3)]:

DEFINITION. *M* is called an *f*-module if every s.o.p. a_1, \dots, a_d of *M* is a filter-regular *M*-sequence, i.e.

$$\mathfrak{q}_{i-1}M: a_i \subseteq igcup_{n=1}^{\infty} \mathfrak{q}_{i-1}M: \mathfrak{m}^n$$

for $i = 1, \dots, d$.

By Lemma 1.1 (iv), every generalized C-M module is an f-module. Of course, f-modules themselves have many interesting properties.

LEMMA 1.2 [6, (2.5) and (2.11)]. The following conditions are equivalent:

(i) M is an f-module.

(ii) Every s.o.p. a_1, \dots, a_d of M is reducing, i.e.

$$I(\mathfrak{q}; M) = l(\mathfrak{q}_{d-1}M: a_d/\mathfrak{q}_{d-1}M).$$

(iii) Every s.o.p. a_1, \dots, a_d of M is unmixed up to \mathfrak{m} , i.e. dim $A/\mathfrak{p} = d - i$ for all $\mathfrak{p} \in \operatorname{Ass}(M/\mathfrak{q}_i M) \setminus \{\mathfrak{m}\}$ and $i = 0, \dots, d - 1$.

(iv) $M_{\mathfrak{p}}$ is a Cohen-Macaulay module with dim $M_{\mathfrak{p}} = d - \dim A/\mathfrak{p}$ for all $\mathfrak{p} \in \operatorname{Supp}(M) \setminus \{\mathfrak{m}\}.$

NGÔ VIÊT TRUNG

Remark 1.3. The notion of reducing s.o.p.'s was introduced by M. Auslander and D.A. Buchsbaum in [2, § 4]. There they showed for every s.o.p. a_1, \dots, a_d of M that

(1) $I(q; M) = l(q_{d-1}M; a_d/q_{d-1}M) + \sum_{i=1}^{d-1} e(q; q_{i-1}M; a_i/q_{i-1}M).$

(2) $I(\mathfrak{q}; M) = l(\mathfrak{q}_{d-1}M; a_d/\mathfrak{q}_{d-1}M)$ iff $a_i \notin \mathfrak{p}$ for all $\mathfrak{p} \in Ass(M/\mathfrak{q}_{i-1}M)$ with dim $A/\mathfrak{p} \ge d - i$ and $i = 1, \dots, d$.

In most of practical situations, *f*-modules coincide with generalized C-M modules by the following result:

LEMMA 1.4 [6, (3.8)]. Let A be a factor of a C-M ring. Then M is an f-module iff M is a generalized C-M module (cf. also [32]).

In such situations, Lemma 1.2 (iv) provides a powerful criterion for generalized C-M modules. For example, it is easily seen from this criterion that the local rings of isolated singularities or of the vertices of affine cones over projective curves are always generalized C-M rings.

Now we will give some basic properties of generalized C-M modules.

LEMMA 1.5 [6, (3.7)]. Let M be a generalized C-M module. Then

$$I(M) = \sum\limits_{i=0}^{d-1} {d -1 \choose i} l(H^i_{\mathfrak{m}}(M))$$
 .

Moreover, there exists a positive integer n such that I(q; M) = I(M) for every parameter ideal $q \subseteq \mathfrak{m}^n$ of M.

LEMMA 1.6. Let M be a generalized C-M module. Then \overline{M} is a generalized C-M module with

(i) $H^{0}_{\mathfrak{m}}(\overline{M}) = 0, \ H^{i}_{\mathfrak{m}}(\overline{M}) \cong H^{i}_{\mathfrak{m}}(M) \ \text{for} \ i \ge 1.$ (ii) $I(\overline{M}) = I(M) - l(H^{0}_{\mathfrak{m}}(M)).$

Proof. (i) follows from the exact sequence

$$0 \longrightarrow H^{\circ}_{\mathfrak{m}}(M) \longrightarrow M \longrightarrow \overline{M} \longrightarrow 0.$$

(ii) is a consequence of Lemma 1.5 and (i).

LEMMA 1.7. Let M be a generalized C-M module with $d \ge 2$. Let a be part of a s.o.p. of M. Then $M_1 := M/aM$ is a generalized C-M module with

- (i) $l(H^i_m(M_1)) \leq l(H^i_m(M)) + l(H^{i+1}_m(M))$ for $i = 0, \dots, d-2$.
- (ii) $I(M_1) \leq I(M)$.

Moreover, equality holds in (i) and (ii) iff $aH^i_{\mathfrak{m}}(M) = 0$ for all $i = 0, \dots, d-1$.

Proof. From the derived local cohomology sequence of the exact sequence

$$0 \longrightarrow M/0_{\scriptscriptstyle M} \colon a \stackrel{a}{\longrightarrow} M \longrightarrow M_{\scriptscriptstyle 1} \longrightarrow 0$$

we can easily deduce that

$$l(H^{i}_{\mathfrak{m}}(M_{\mathfrak{l}})) \leq l(H^{i}_{\mathfrak{m}}(M)) + l(H^{i+1}_{\mathfrak{m}}(M/0_{\mathfrak{M}};a))$$

for $i = 0, \dots, d-2$. Note that $0_M : a \subseteq H^0_m(M)$ by Lemma 1.1 (iv). Then from the exact sequence

$$0 \longrightarrow 0_M \colon a \longrightarrow M \longrightarrow M/0_M \colon a \longrightarrow 0$$

we get $H^i_{\mathfrak{m}}(M/\mathfrak{0}_M:a) \cong H^i_{\mathfrak{m}}(M)$ for $i \ge 1$. Hence (i) is obvious. Now, using Lemma 1.5 we have

$$egin{aligned} &I(M_{ ext{l}}) = \sum\limits_{i=0}^{d-2} {d-2 \choose i} l(H^i_{ ext{m}}(M_{ ext{l}})) \ &\leq \sum\limits_{i=0}^{d-2} {d-2 \choose i} [l(H^i_{ ext{m}}(M)) + l(H^{i+1}_{ ext{m}}(M))] \ &= \sum\limits_{i=0}^{d-1} {d-1 \choose i} l(H^i_{ ext{m}}(M)) = I(M) \ . \end{aligned}$$

Clearly, equality holds above iff the sequence

$$0 \longrightarrow H^{i}_{\mathfrak{m}}(M) \longrightarrow H^{i}_{\mathfrak{m}}(M_{1}) \longrightarrow H^{i+1}_{\mathfrak{m}}(M/0_{M}; a) \longrightarrow 0$$

is exact for all $i = 0, \dots, d-2$. But that is the case iff $H^{0}_{\mathfrak{m}}(M/0_{\mathfrak{M}}; a) = 0$, i.e. $aH^{0}_{\mathfrak{m}}(M) = 0$, and $aH^{i}_{\mathfrak{m}}(M/0_{\mathfrak{M}}; a) = aH^{i}_{\mathfrak{m}}(M) = 0$ for $i = 1, \dots, d-1$. So we have proved (ii) and the statement about equality.

§2. Standard systems of parameters

DEFINITION. a_1, \dots, a_d is called a standard s.o.p. of M if

$$I(a_1^2, \cdots, a_d^2; M) = I(\mathfrak{q}; M)$$
 .

This definition of standard s.o.p.'s is different from the one given in the introduction of this paper but leads to the same notion by the following result:

THEOREM 2.1. a_1, \dots, a_d is a standard s.o.p. of M iff M is a generalized C-M module with I(M) = I(q; M). Properly speaking, Theorem 2.1 is a criterion for generalized C-M modules. It is rather surprising how a simple condition on a s.o.p. implies all the global properties of a generalized C-M module.

For the proof of Theorem 2.1 we shall need the following auxiliary result:

LEMMA 2.2. Let
$$a_1, \dots, a_d$$
 be an arbitrary s.o.p. of M . Then $I(a_1^{n_1}, \dots, a_d^{n_d}; M) \leq I(a_1^{m_1}, \dots, a_d^{m_d}; M)$

for all positive integers $n_1 \leq m_1, \dots, n_d \leq m_d$.

Proof. By induction we may assume that $n_i = m_i$ for i < d. Then

$$\begin{split} l((a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}})M;\,a_d^{n_d}/(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}})M) \\ &\leq l((a_a^{n_1},\cdots,a_{d-1}^{n_d-1})M;\,a_d^{n_d}/(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}})M)\,, \\ e(a_1^{n_1},\cdots,a_d^{n_d};\,(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M;\,a_i^{n_i}/(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M) \\ &= n_d e(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}},a_d;\,(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M;\,a_i^{n_i}/(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M) \\ &\leq m_d e(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}},a_d;\,(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M;\,a_i^{n_i}/(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M) \\ &= e(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}},a_d^{m_d};\,(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M;\,a_i^{n_i}/(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M) \end{split}$$

for $i = 1, \dots, d - 1$. Hence, applying Remark 1.3 (1) we get

$$I(a_1^{n_1}, \cdots, a_d^{n_d}; M) \leq I(a_1^{n_1}, \cdots, a_{d-1}^{n_{d-1}}, a_d^{n_d}; M).$$

Proof of Theorem 2.1. (\Rightarrow) By Lemma 1.1 (iii) and Lemma 1.5 we only need to show that

$$I(a_1^{n_1}, \cdots, a_d^{n_d}, M) = I(\mathfrak{q}; M)$$

for all positive integers n_1, \dots, n_d . First, using Lemma 2.2 and the definition of standard s.o.p.'s we get equality for $n_1, \dots, n_d \in \{1, 2\}$. If there exist positive integers n_1, \dots, n_d such that

$$I(a_1^{n_1}, \cdots, a_d^{n_d}; M)
eq I(\mathfrak{q}; M)$$
,

we must have $\max\{n_1, \dots, n_d\} > 2$. Without restriction we may assume that

$$n_{\scriptscriptstyle d} = \max\left\{n_{\scriptscriptstyle 1},\,\cdots,\,n_{\scriptscriptstyle d}
ight\} > 2$$
 .

Then, by induction, we may further assume that

$$I(a_1^{n_1}, \cdots, a_{d-1}^{n_{d-1}}, a_d; M) = I(a_1^{n_1}, \cdots, a_{d-1}^{n_{d-1}}, a_d^{n_{d-1}}; M) = I(q; M).$$

Hence, looking at the proof of Lemma 2.2, we can conclude that

$$\begin{split} l((a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}})M:a_d/(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}})M) \\ &= l((a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}})M:a_d^{n_{d-1}}/(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}})M), \\ e(a_1^{n_1},\cdots,a_{d-1}^{n_{d-1}},a_d;(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M:a_i^{n_i}/(a_1^{n_1},\cdots,a_{i-1}^{n_{i-1}})M) = 0 \end{split}$$

for $i = 1, \dots, d - 1$. From the first equation we get

$$(a_1^{n_1}, \cdots, a_{d-1}^{n_{d-1}})M: a_d = (a_1^{n_1}, \cdots, a_{d-1}^{n_{d-1}})M: a_d^{n_{d-1}} = (a_1^{n_1}, \cdots, a_{d-1}^{n_{d-1}})M: a_d^{n_d},$$

hence, applying Remark 1.3 (1),

$$I(a_1^{n_1}, \cdots, a_d^{n_d}; M) = I(a_1^{n_1}, \cdots, a_{d-1}^{n_{d-1}}, a_d; M) = I(q; M)$$
,

a contradiction.

(\Leftarrow) Since $I(a_1^2, \dots, a_d^2; M) = I(M) = I(q; M)$, applying Lemma 2.2 we must have $I(a_1^2, \dots, a_d^2; M) = I(q; M)$, as required.

For reduction process we shall need the following consequences of Theorem 2.1.

COROLLARY 2.3. a_1, \dots, a_d is a standard s.o.p. of M iff a_1, \dots, a_d is a standard s.o.p. of \overline{M} and $\mathfrak{q}M \cap H^0_{\mathfrak{m}}(M) = 0$.

Proof. Since $H^{0}_{\mathfrak{m}}(M)$ is of finite length, we have $e(\mathfrak{q}; \overline{M}) = e(\mathfrak{q}; M)$. Thus,

$$egin{aligned} I(\mathfrak{q};\overline{M}) &= l(M/\mathfrak{q}M + H^{\mathfrak{o}}_{\mathfrak{m}}(M)) - e(\mathfrak{q};\overline{M}) \ &= l(M/\mathfrak{q}M) - l(\mathfrak{q}M + H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}M) - e(\mathfrak{q};M) \ &= I(\mathfrak{q};M) - l(H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}M \cap H^{\mathfrak{o}}_{\mathfrak{m}}(M)) \ &= I(\mathfrak{q};M) - l(H^{\mathfrak{o}}_{\mathfrak{m}}(M)) + l(\mathfrak{q}M \cap H^{\mathfrak{o}}_{\mathfrak{m}}(M)) \ . \end{aligned}$$

Now, using the relation $I(\overline{M}) = I(M) - l(H^0_{\mathfrak{m}}(M))$ of Lemma 1.6 (ii), we easily get the statement.

COROLLARY 2.4. Let M be a generalized C-M module with $d \ge 2$. Then a_1, \dots, a_d is a standard s.o.p. of M iff a_2, \dots, a_d is a standard s.o.p. of M/a_1M and $I(M/a_1M) = I(M)$.

Proof. By Lemma 1.2 (ii) and Lemma 1.7, we have

$$I(a_2, \cdots, a_d; M/a_1M) = l(\mathfrak{q}_{d-1}M; a_d/M) = I(\mathfrak{q}; M).$$

Hence the statement can be easily derived from Lemma 1.7 (ii).

Now we shall show that standard s.o.p.'s may be characterized by means of local cohomology (see Theorem 3.4 for further homological characterization).

THEOREM 2.5. a_1, \dots, a_d is a standard s.o.p. of M iff

 $\mathfrak{q}H^i_{\mathfrak{m}}(M/\mathfrak{q}_{\mathfrak{k}}M)=0$

for all non-negative integers i, j with i + j < d.

Proof. Without restriction we may assume that M is a generalized C-M module. If d = 1, we have

$$I(a_1; M) = l(0_M; a_1)$$

 $I(a_1^2; M) = l(0_M; a_1^2)$

by Lemma 1.2 (ii). Therefore, a_1 is a standard s.o.p. of M iff $0_M: a_1 = 0_M: a_1^2$ or, equivalently,

$$\mathbf{0}_{\scriptscriptstyle M} \colon a_1 = \sum_{n=1}^{\infty} \mathbf{0}_{\scriptscriptstyle M} \colon a_1^n = \bigcup_{n=1}^{\infty} \mathbf{0}_{\scriptscriptstyle M} \colon \mathfrak{m}^n = H^0_{\mathfrak{m}}(M).$$

So we have proved the case d = 1. For d > 1 we set $M_1 = M/a_1M$.

If a_1, \dots, a_d is a standard s.o.p. of M, then a_1, \dots, a_d is also a standard s.o.p. of M_1 and $I(M_1) = I(M)$ by Corollary 2.4. By induction we have

$$\mathfrak{q}H^i_{\mathfrak{m}}(M/\mathfrak{q}_{\mathfrak{l}}M)=0$$

for all $j \ge 1$, i + j < d. Moreover, $a_1 H^i_m(M) = 0$ for all $i = 0, \dots, d-1$ by Lemma 1.7. Hence, permuting a_1, \dots, a_d we also get $\mathfrak{q} H^i_m(M) = 0$ for $i = 0, \dots, d-1$.

Conversely, if

$$\mathfrak{q}H^i_{\mathfrak{m}}(M/\mathfrak{q}_iM)=0$$

for all i + j < d, then a_2, \dots, a_d is a standard s.o.p. of M_1 by induction and $I(M_1) = I(M)$ by Lemma 1.7. Hence a_1, \dots, a_d is a standard s.o.p. of M by Corollary 2.4. The proof of Theorem 2.5 is now complete.

In [3], [4], M. Brodmann calls a sequence b_1, \dots, b_r of elements of \mathfrak{m} an \mathfrak{m} -standard M-sequence if b_1, \dots, b_r is a filter-regular M-sequence and

$$(b_1, \cdots, b_r)H^i_{\mathfrak{m}}(M/(b_1, \cdots, b_r)M) = 0$$

for all non-negative integers i, j with

$$i+j < \max\{n; l(H^t_{\mathfrak{m}}(M)) < \infty \text{ for } t < n\}.$$

Hence, by Theorem 2.5, standard s.o.p.'s are m-standard sequences. That is why we choose the name "standard".

Theorem 2.5 has some interesting consequences.

COROLLARY 2.6. Let a_1, \dots, a_d be a standard s.o.p. of M. Then (i) a_1, \dots, a_d is a d-sequence of M, i.e.

$$\mathfrak{q}_{i-1}M$$
: $a_ia_j = \mathfrak{q}_{i-1}M$: a_i^2

for $i = 1, \dots, d$ and j > i.

(ii) a_1, \dots, a_d is an absolutely superficial M-sequence, i.e.

$$[(\mathfrak{q}^{n+1},\mathfrak{q}_{i-1})M:a_i]\cap\mathfrak{q}M=(\mathfrak{q}^n,\mathfrak{q}_{i-1})M$$

for all $n \geq 0$, $i = 1, \dots, d$.

(iii) $(\mathfrak{q}_{i-1}M:a_i)\cap\mathfrak{q}(a_i,\cdots,a_d)^nM=\mathfrak{q}_{i-1}(a_i,\cdots,a_d)^nM$ for all $n\geq 0,$ $i=1,\cdots,d.$

- (iv) $\mathfrak{q}_{i-1}M$: $a_i^n = \mathfrak{q}_{i-1}M$: \mathfrak{q}^m for all $m, n > 0, i = 1, \dots, d$.
- (v) $(q^{n+1}, q_{i-1})M: a_i = q^n M + (q_{i-1}M: a_i)$ for all $n > 0, i = 1, \dots, d$.

Proof. By [27, Theorem 1.1, Corollary 1,2 (iii), and Acknowledgement], conditions (i) to (iv) are equivalent to each other and to the condition

$$\mathfrak{q}_{i-1}M$$
: $a_i = igcup_{n=1}^{\infty} \mathfrak{q}_{i-1}M$: \mathfrak{m}^n

for all $i = 1, \dots, d$, and they imply (v). By Lemma 1.1 (iv), it is sufficient to show that

$$\mathfrak{q}_{i-1}M: a_i \supseteq igcup_{n=1}^{\infty} \mathfrak{q}_{i-1}M: \mathfrak{m}^n$$
 ,

which follows from the fact

$$a_i H^0_{\mathfrak{m}}(M/\mathfrak{g}_{i-1}M) = 0$$

of Theorem 2.5.

In particular, one can characterize standard s.o.p.'s by means of d-sequences as follows.

PROPOSITION 2.7. a_1, \dots, a_d is a standard s.o.p. of M iff by every permutation, $a_1^{n_1}, \dots, a_d^{n_d}$ is a d-sequence of M for all $n_1, \dots, n_d \in \{1, 2\}$.

Proof. (\Rightarrow) By Theorem 2.1 and Lemma 2.2,

$$I(M) = I(\mathfrak{q}; M) \leq I(a_1^{n_1}, \cdots, a_d^{n_d}; M) \leq I(M)$$
.

Therefore, $a_1^{n_1}, \dots, a_d^{n_d}$ is also a standard s.o.p., hence a *d*-sequence of *M* by Corollary 2.6 (i).

(\Leftarrow) By [27, Theorem 1.1 (vii)] and Remark 1.3 (2), $a_1^{n_1}, \dots, a_d^{n_d}$ is a reducing s.o.p. of *M*. Hence, using [27, Theorem 1.1 (vi)], we get

$$egin{aligned} I(a_1^{n_1},\,\cdots,\,a_{d-1}^{n_d})M&:=l((a_1^{n_1},\,\cdots,\,a_{d-1}^{n_{d-1}})M):a_d^{n_d}/(a_1^{n_1},\,\cdots,\,a_{d-1}^{n_{d-1}})M)\ &=l((a_1^{n_1},\,\cdots,\,a_{d-1}^{n_{d-1}})M):a_d/(a_1^{n_1},\,\cdots,\,a_{d-1}^{n_{d-1}})M)\ &=I(a_1^{n_1},\,\cdots,\,a_{d-1}^{n_{d-1}},\,a_d\,;\,M)\,. \end{aligned}$$

Now, permuting a_1, \dots, a_d , we can easily show that

$$I(a_1^2, \cdots, a_d^2; M) = I(\mathfrak{q}; M)$$
 .

Remark 2.8. There are many criteria for a_1, \dots, a_d to be a *d*-sequence of M [27, Theorem 1.1]. The simplest ones are the following:

- (1) $(\mathfrak{q}_{i-1}M:a_i) \cap \mathfrak{q}M = \mathfrak{q}_{i-1}M$ for $i = 1, \dots, d$.
- (2) $q_{i-1}M: a_i^2 \subseteq q_{i-1}M: q \text{ for } i = 1, \dots, d.$
- (3) $q_{i-1}M: a_i = \bigcup_{n=1}^{\infty} q_{i-1}M: \mathfrak{m}^n$ for $i = 1, \dots, d$.

The following result shows, together with Theorem 2.1, that some numerical invariants of a_1, \dots, a_d relative to M will reach their maximal value iff a_1, \dots, a_d is a standard s.o.p. of M (see also Theorem 4.1 and Corollary 4.2).

PROPOSITION 2.9. Let M be a generalized C-M module. Then

$$l(H^i_{\mathfrak{m}}(M/\mathfrak{q}_jM)) \leq \sum_{t=i}^{i+j} {j \choose t-1} l(H^t_{\mathfrak{m}}(M))$$

for all non-negative integers i, j with i + j < d. Equalities hold above by every permutation of a_1, \dots, a_d iff a_1, \dots, a_d is a standard s.o.p. of M.

Proof. For j = 0 there is nothing to prove, For j > 0 we have the following inequality

$$l(H^{i}_{\mathfrak{m}}(M/\mathfrak{q}_{i}M)) \leq l(H^{i}_{\mathfrak{m}}(M/\mathfrak{q}_{i-1}M)) + l(H^{i+1}_{\mathfrak{m}}(M/\mathfrak{q}_{i-1}M))$$

by Lemma 1.7 (i). Applying this inequality successively, we then get the first statement. Moreover, by Lemma 1.7, equality holds above for a fixed j < d and all $i = 0, \dots, d - j - 1$ iff

$$a_j H^i_{\mathfrak{m}}(M/\mathfrak{q}_{j-1}M) = 0$$

for all $i = 0, \dots, d - j$. Hence, using Theorem 2.5, we also get the second statement.

We conclude this section by establishing, explicitly, the ubiquity of standard s.o.p.'s in a generalized C-M module, cf. Lemma 1.5.

PROPOSITION 2.10. Let M be a generalized C-M module. Let $\alpha_i(M)$ denote the annihilator of $H^i_{\mathfrak{m}}(M)$, $i = 0, \dots, d-1$, and set

$$\mathfrak{a}_{\scriptscriptstyle M}=\prod_{i=0}^{d-1}a_i(M)^{\binom{d-1}{i}}.$$

Then every s.o.p. of M contained in α_M is standard.

Proof. Let a_1, \dots, a_d be a s.o.p. of M contained in α_M . By Theorem 2.5, to show that a_1, \dots, a_d is a standard s.o.p. of M, it is sufficient to show that

$$a_i(M/\mathfrak{q}_jM) \supseteq \mathfrak{a}_M$$

for all non-negative integers i, j with i + j + d. For j = 0, that is immediate. For j > 0, we have

$$a_i(M/\mathfrak{q}_jM) \supseteq a_i(M/\mathfrak{q}_{j-1}M)a_{i+1}(M/\mathfrak{q}_{j-1}M)$$

by the proof of Lemma 1.7 (i). Using this relation successively, we get

$$a_i(M/\mathfrak{q}_jM)\supseteq \prod_{\iota=i}^{i+j}a_\iota(M)^{\binom{j}{\iota-i}}\supseteq \mathfrak{a}_M$$
 ,

because

$$\binom{j}{t-i} = \binom{j}{i+j-t} \leq \binom{i+j}{i+j-t} = \binom{i+j}{t} \leq \binom{d-1}{t}.$$

§ 3. Standard ideals

Throughout this section, M will be a generalized C-M module and α an ideal of A with $l(M|\alpha M) < \infty$.

DEFINITION. α is called an *M*-standard ideal if every s.o.p. of *M* contained in α is standard.

This notion extends the one introduced in [3], [4], where standard ideals are, roughly speaking, ideals generated by standard s.o.p.'s, cf. Corollary 3.3 below. The existence of standard ideals is guaranteed by Lemma 1.5 or, explicitly, by Proposition 2.10. In particular, M being a Buchsbaum module just means that m is M-standard.

First, we shall see that standard ideals may be also characterized by means of d-sequences and weak sequences. The latter ones were introduced in [27] as follows. DEFINITION. A sequence of elements b_1, \dots, b_r of A is called an aweak M-sequence if

$$(b_1, \cdots, b_{i-1})M$$
: $b_i \subseteq (b_1, \cdots, b_{i-1})M$: a

for all $i = 1, \dots, r$.

It should be mentioned that m-weak sequences are known as weak sequences and play an important role in the theory of Buchsbaum modules [22], [23].

PROPOSITION 3.1. The following conditions are equivalent:

- (i) a is M-standard.
- (ii) Every s.o.p. of M contained in α is an α -weak M-sequence.
- (iii) Every s.o.p. of M contained in α is a d-sequence of M.

Proof. (i) \Rightarrow (ii). Let a_1, \dots, a_d be an arbitrary s.o.p. of M contained in α . Let S be a generating set for α such that every d element subset of $S \cup \{a_1, \dots, a_d\}$ forms a s.o.p. of M, where the existence of such a set S can be easily shown as in [21, Lemma 2] or [25, Lemma 3]. Then, by Corollary 2.6 (iv),

$$\mathfrak{q}_{i-1}M$$
: $a_i = igcup_{n=1}^{\infty}\mathfrak{q}_{i-1}M$: $\mathfrak{m}^n = igcup_{a\in S}\mathfrak{q}_{i-1}M$: $a = \mathfrak{q}_{i-1}M$: a

for all $i = 1, \dots, d$. (ii) \Rightarrow (iii) follows from [27, Proposition 2.2]. (iii) \Rightarrow (i) follows from Proposition 2.7.

For practical uses, the following characterization of standard ideals is more convenient than Proposition 3.1 because it depends only on a finite system of elements.

In order to simplify our statement, we call a finite generating set S for α an M-base of α if every d element subset of S forms a s.o.p. of M, see [21, Lemma 2] or [25, Lemma 3] for the existence of M-bases of α .

PROPOSITION 3.2. a is M-standard iff one of the following conditions holds for all d element subsets $\{a_1, \dots, a_d\}$ of an M-base of a:

- (i) a_1, \dots, a_d is a standard s.o.p. of M.
- (ii) $a_1^{n_1}, \dots, a_d^{n_d}$ is an α -weak M-sequence for all $n_1, \dots, n_d \in \{1, 2\}$.
- (iii) $a_1^{n_1}, \dots, a_d^{n_d}$ is a d-sequence of M for all $n_1, \dots, n_d \in \{1, 2\}$.

Proof. That a being *M*-standard implies (ii) follows from Proposition 3.1. (ii) \Rightarrow (iii) is a consequence of [27, Proposition 2.2]. (iii) \Rightarrow (i) follows from Proposition 2.7. Now suppose that (i) is satisfied. Then we have

to show that every s.o.p. b_1, \dots, b_d of M contained in α is standard. If d = 1, using Corollary 2.6 (iv) we have

$$0_M: b_1 \supseteq 0_M: \mathfrak{a} = \bigcap_{a \in S} 0_M: a = \bigcup_{n=1}^{\infty} 0_M: \mathfrak{m}^n \supseteq 0_M: b_1.$$

Thus, $0_M: b_1 \supseteq H^0_{\mathfrak{m}}(M)$. Hence b_1 is a standard s.o.p. of M by Theorem 2.5. If d > 1, we can find a generating set S' for a such that a_1, \dots, a_{d-1}, b and b_1, \dots, b_{d-1}, b are s.o.p.'s of M for all $b \in S'$ and $\{a_1, \dots, a_{d-1}\} \subset S$ by the same method of [25, Lemma 3]. Using Corollary 2.6 (iv), we first have

$$\mathfrak{q}_{d-1}M:b\supseteq\mathfrak{q}_{d-1}M:\mathfrak{a}=igcap_{d\in S}\mathfrak{q}_{d-1}M:a=igcup_{n=1}^{\infty}\mathfrak{q}_{d-1}M:\mathfrak{m}^n\supseteq\mathfrak{q}_{d-1}M:b$$

and then

$$\mathfrak{q}_{d-1}M:b=\bigcup_{n=1}^{\infty}\mathfrak{q}_{d-1}M:\mathfrak{m}^n=\mathfrak{q}_{d-1}M:a_d$$

Therefore, by virtue of Lemma 1.2 (ii) and Theorem 2.1,

$$I(a_1, \dots, a_{d-1}, b; M) = l(\mathfrak{q}_{d-1}M; b/\mathfrak{q}_{-1}M) = l(\mathfrak{q}_{d-1}M; a_d/\mathfrak{q}_{d-1}M)$$

= $I(\mathfrak{q}; M) = I(M)$,

i.e. a_1, \dots, a_{d-1}, b is a standard s.o.p. of M. It follows by Corollary 2.4 that a_1, \dots, a_{d-1} is a standard s.o.p. of M/bM and I(M/bM) = I(M). Now, by induction, we may assume that a is M/bM-standard. Then

$$I(b_1, \dots, b_{d-1}, b; M) = I(M/bM) = I(M)$$

i.e. b_1, \dots, b_{d-1} , b is a standard s.o.p. of M too. Since the elements b generate a, we can show, similarly as above, that

$$I(b_1, \cdots, b_d; M) = I(M)$$
.

The proof of Proposition 3.2 is now complete.

Proposition 3.2 immediately leads to the following consequence which justifies our notion of standard ideals from Brodmann's notion in [3], [4].

COROLLARY 3.3. Every ideal of A generated by a standard s.o.p. of M is M-standard.

Next, we shall show that standard ideals may be characterized by homological means, inspired from the so-called surjectivity criterion of Buchsbaum modules [21, Satz 1]. We point out that the proof for [21, Satz 1] could not be extended for our case.

First, we recall some facts about Koszul cohomology.

Let K(S; N) denote the Koszul complex of an arbitrary A-module N with respect to a generating set S of a. If $S = \{b_1, \dots, b_r\}$, then K(S; N)may be viewed as the complex of the exterior products generated over N by r indeterminates X_1, \dots, X_r with the boundary map $X_i \rightarrow b_i$, i = 1, \dots, r . Let $H_i(S; N)$ and $H^i(S; N)$ denote the homology and cohomology of K(S; N), respectively. Then

$$H^{i}(S; N) \cong H_{r-i}(S; N)$$

does not depend on the choice of S and will be denoted by $H^{i}(\alpha; N)$, $i = 0, \dots, r$. It is well-known that

$$H^i_{\mathfrak{m}}(M) = \varinjlim_n H^i(\mathfrak{a}^n; M)$$

for all $i = 1, \dots, d$.

THEOREM 3.4. a is M-standard iff the natural homomorphism

 $\varphi_i: H^i(\mathfrak{a}; M) \longrightarrow H^i_{\mathfrak{m}}(M)$

is surjective for $i = 0, \dots, d - 1$.

Proof. (\Rightarrow) Let S be an M-base of \mathfrak{a} . Then

$$\mathbf{0}_M:\mathfrak{a}=\bigcap_{a\in S}\mathbf{0}_M:a=\bigcup_{n=1}^{\infty}\mathbf{0}_M:\mathfrak{m}^n$$

by Corollary 2.6 (iv). Hence

$$\varphi_0: H^0(\mathfrak{a}; M) = 0_M: \mathfrak{a} \longrightarrow H^0_{\mathfrak{m}}(M) = \bigcup_{n=1}^{\infty} 0_M: \mathfrak{m}^n$$

is surjective. Thus, we may assume that d > 1, and, we only need to show that φ_i is surjective for $i = 1, \dots, d - 1$. Note that $\overline{M} = M/H^0_{\mathfrak{m}}(M)$. Then we have the commutative diagram

Consequently, φ_i is surjective if α_i and $\overline{\varphi}_i$ are surjective.

Assume that $S = \{a_1, \dots, a_r\}$. Then α_i is surjective if every (r - i)th cycle \overline{e} of $K(S; \overline{M})$ is the natural image of some (r - i)th cycle e of

K(S; M). Write

$$ar{e} = \sum \overline{m}_{(u)} X_{u_1} \cdots X_{u_{r-i}}$$
 ,

 $\overline{m}_{(u)} \in \overline{M}$, where (u) runs through all sets $\{u_1, \dots, u_{r-i}\}$ of integers between 1 and r. Let $m_{(u)}$ be elements of M whose images in \overline{M} are $\overline{m}_{(u)}$. Let $(v) = \{v_1, \dots, v_{r-i-1}\}$ be a set of integers with $i \leq v_1 < \dots < v_{r-i-1} \leq r$ and $\{t_1, \dots, t_{i+1}\}$ the complement of (v) in $\{1, \dots, r\}$. Put

$$n_{(v)} = \sum_{j=1}^{i+1} (-1)^{\operatorname{sig}(t_j,v)} a_{t_j} m_{(t_j,v)}$$

Then $n_{(v)} \in H^0_{\mathfrak{m}}(M)$ because \overline{e} is a (r-i)th cycle of $K(S; \overline{M})$. Since

$$H^0_{\mathfrak{m}}(M)\cap (a_{t_1},\cdots,a_{t_{i+1}})M=0$$

by Corollary 2.3, we must have $n_{(v)} = 0$. That means

$$e = \sum m_{(u)} X_{u_1} \cdots X_{u_{r-u}}$$

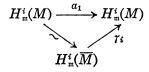

is a (r - i)th cycle of K(S; M), as required.

To show that $\bar{\varphi}_i$ is surjective we consider the exact sequence

$$0 \longrightarrow M/0_{\scriptscriptstyle M} : a_1 \xrightarrow{a_1} M \longrightarrow M/a_1 M \longrightarrow 0.$$

Note that $0_M: a_1 = \bigcup_{n=1}^{\infty} 0_M: \mathfrak{m}^n$ by Corollary 2.6 (iv). Then $M/0_M: a_1 = \overline{M}$ and we get the following commutative diagram

Since a is M/a_1M -standard by Corollary 2.3, by induction we may assume that ϕ_{i-1} is surjective. Further, since $a_1H^i_{\mathfrak{m}}(M) = 0$ by Theorem 2.5, from the commutative diagram

we can deduce that γ_i is zero. Hence β_i is surjective and so is $\overline{\varphi}_i$ too. So we have proved the necessary part.

 (\Rightarrow) We will show that every s.o.p. a_1, \dots, a_b of M contained in a

is a d-sequence of M, which then implies that α is M-standard by Proposition 3.1. By Remark 2.8 (2) it suffices to show that

$$\mathfrak{q}_{i-1}M$$
: $a_i^2 \subseteq \mathfrak{q}_{i-1}M$: \mathfrak{q}

for $i = 1, \dots, d$. First, we have $\alpha H^0_m(M) = 0$ because φ_0 is surjective. From this and Lemma 1.1 (iv) it follows that

$$0_{\scriptscriptstyle M}$$
: $a_1^2 \subseteq igcup_{n=1}^\infty 0_{\scriptscriptstyle M}$: $\mathfrak{m}^n \subseteq 0_{\scriptscriptstyle M}$: $\mathfrak{a} \subseteq 0_{\scriptscriptstyle M}$: \mathfrak{q} .

Hence the case i = 1 is immediate. For i > 1 we consider the following exact sequences

$$H^{i-1}(a_1^n, \cdots, a_j^n; M) \xrightarrow{\gamma_j^n} H^{i-1}(a_1^n, \cdots, a_{j-1}^n; M) \xrightarrow{a_j^n} H^{i-1}(a_1^n, \cdots, a_{j-1}^n; M),$$

 $j = i + 1, \dots, d$ [2, Proposition 1.1]. Note that for *n* large, a_1^n, \dots, a_d^n is a standard s.o.p. of *M* by Lemma 1.5, hence a *d*-sequence by Corollary 2.6 (i). Then

$$a_{j}^{n}H^{i-1}(a_{1}^{n}, \cdots, a_{j-1}^{n}; M) = 0$$

by [13, § 5] (which was proved for rings but could be easily extended for modules). Hence $\tilde{\tau}_j^n$ is surjective and so is

$$\Upsilon_d^n \circ \cdots \circ \Upsilon_{i+1}^n \colon H^{i-1}(a_1^n, \cdots, a_d^n; M) \longrightarrow H^{i-1}(a_1^n, \cdots, a_i^n; M)$$
.

Thus, we have the following commutative diagram

Now let $m_i \in q_{i-1}M$: a_i^2 arbitrary. Then

$$a_i^2 m_i = -\sum_{j=1}^{i-1} a_j m_j$$

for some $m_j \in M$. Clearly, m_1, \dots, m_i define a cycle of $K(a_1, \dots, a_{i-1}, a_i^2; M)$

$$e=\sum_{j=1}^{i}m_{j}X_{j}$$
.

By virtue of the above diagram, we can find a cycle of $K(a_1, \dots, a_{i-1}, a_i^2; M)$

$$f = \sum_{j=1}^{i} n_j X_j$$

such that

- (1) f is the image of some (d i 1)th cycle of $K(a_1, \dots, a_d; M)$,
- (2) The image of e f in $H^{i-1}_{q_i}(M)$ is zero.

From (1) we can deduce that $a_j n_i \in q_{i-1}M$ for all $j = 1, \dots, d$, i.e. $n_i \in q_{i-1}M$: q. From (2) we can deduce that there exist integers n such that the image of e - f in $K(a_1^n, \dots, a_i^n; M)$ is a boundary. From this it follows that

$$(a_1 \cdots a_{i-1})^{n-1}(m_i - n_i) \in (a_1^n, \cdots, a_{i-1}^n)M$$

Note that by induction we have

$$\mathfrak{q}_{j-1}M$$
: $a_j^2\subseteq\mathfrak{q}_{j-1}M$: $\mathfrak{q}\subseteq\mathfrak{q}_{j-1}M$: $\mathfrak{q}_{i-1}\subseteq\mathfrak{q}_{j-1}M$: a_j^2

and hence $q_{j-1}M: a_j^2 = q_{j-1}M: q_{i-1}$ for $j = 1, \dots, i-1$. Then a_1, \dots, a_{i-1} is a *d*-sequence of *M* by [27, Theorem 1.1 (v)]. So we may assume that every subsystem of parameters of *M* of i-1 elements contained in q is a *d*-sequence of *M* and therefore a q-weak *M*-sequence by [27, Proposition 2.3]. Now, by virtue of the following Lemma 3.5, we have

$$m_i - n_i \in (a_1^n, \cdots, a_{i-1}^n) M$$
: $(a_1 \cdots a_{i-1})^{n-1} \subseteq \mathfrak{q}_{i-1} M$: \mathfrak{q} .

Hence, $m_i \in q_{i-1}M$: q, as required. The proof of Theorem 3.4 is now complete.

The following auxiliary result is of independent interest because it establishes the monomial property of certain kind of sequences of elements of A.

LEMMA 3.5 (cf. [9, Theorem 4.7]). Suppose that b_1, \dots, b_r is a system of elements in some ideal b of A such that by every permutation, $b_1^{n_1}, \dots, b_r^{n_r}$ is a b-weak M-sequence for all positive integers n_1, \dots, n_r . Then

$$(b_1^n, \cdots, b_r^n)M; (b_1 \cdots b_r)^{n-1} = (b_1, \cdots, b_r)M + \sum_{j=1}^r (b_1, \cdots, b_j, \cdots, b_r)M; \mathfrak{b}$$

for all $n \geq 2$.

Proof. It is sufficient to show that

$$(b_1^n, \cdots, b_r^n)M$$
: $(b_1 \cdots b_r)^{n-1} \subseteq (b_1, \cdots, b_r)M + \sum_{j=1}^r (b_1, \cdots, b_j, \cdots, b_r)M$: \mathfrak{b} .

The case r = 1 is immediate. For r > 1 let *m* be an arbitrary element of $(b_1^n, \dots, b_r^n)M: (b_1 \dots b_r)^{n-1}$. Then, by induction,

$$b_1^{n-1}m \in (b_1^n, \, b_2, \, \cdots, \, b_r)M + \sum_{j=2}^r (b_1^n, \, b_2, \, \cdots, \, b_j, \, \cdots, \, b_r)M$$
: b.

Thus, there exist elements $m_j \in (b_1^n, b_2, \dots, b_j, \dots, b_r)M$: b such that

$$b_1^{n-1}m=\sum\limits_{j=2}^rm_j \mod (b_2,\,\cdots,\,b_r)M$$
 .

Now we want to show that

$$b_1m_j \in b_1^n[(b_1, \cdots, b_j, \cdots, b_r)M: \mathfrak{b}] + (b_2, \cdots, b_r)M$$

First, we can find elements n_j , $n'_j \in M$ such that

$$egin{array}{lll} b_1m_j &= b_1^nn_j\ b_jm_j &= b_1^nn_j' \end{array}$$

modulo $(b_2, \dots, b_j, \dots, b_r)M$. From this it follows that

$$egin{aligned} b_j n_j &- b_1 n_j' \in (b_2, \ \cdots, \ b_j, \ \cdots, \ b_r) M \colon b_1^n \ &\subseteq (b_2, \ \cdots, \ b_j, \ \cdots, \ b_r) M \colon \mathfrak{b} \subseteq (b_2, \ \cdots, \ b_r) M \colon b_j \,. \end{aligned}$$

Hence

$$n_j \in (b_1, \cdots, b_j, \cdots, b_r)M$$
: $b_j^2 \subseteq (b_1, \cdots, b_j, \cdots, b_r)M$: \mathfrak{b} .

Thus, since

$$m-\sum_{j=2}^r n_j \in (b_2, \cdots, b_r)M$$
: $b_1^n=(b_2, \cdots, b_r)M$: \mathfrak{b} ,

 $m \in \sum_{j=1}^{r} (b_1, \dots, b_j, \dots, b_r) M$: b, as required.

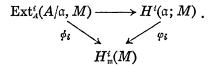

Theorem 3.4 has many interesting consequences.

COROLLARY 3.6 (cf. [23, Theorem 1]). α is M-standard if the natural homomorphism

$$\phi_i \colon \operatorname{Ext}^i_A(A/\mathfrak{a}, M) \longrightarrow H^i_{\mathfrak{m}}(M)$$

is surjective for $i = 0, \dots, d - 1$. If a is generated by a regular A-sequence, the converse also holds.

Proof. The first statement is easily seen from the following commutative diagram

For the second statement we only need to note that if α is generated by a regular A-sequence, then $\operatorname{Ext}_{A}^{i}(A/\mathfrak{a}, M) \cong H^{i}(\alpha; M)$.

COROLLARY 3.7 (cf. [23], Corollary 1.1]). Suppose that there exists a non-negative integer r < d such that $H^i_{\mathfrak{m}}(M) = 0$ for $i \neq r$, d. Then a is *M*-standard iff $\mathfrak{a}H^r_{\mathfrak{m}}(M) = 0$.

Proof. It is sufficient to prove the sufficient part. First, we have

$$H^r(\mathfrak{a}; M) \cong H^0(\mathfrak{a}; M/(a_1, \cdots, a_r)M) = (a_1, \cdots, a_r)M: a/(a_1, \cdots, a_r)M$$

 $H^r_\mathfrak{m}(M) \cong H^0_\mathfrak{m}(M/(a_1, \cdots, a_r)M) = \bigcup_{n=1}^{\infty} (a_1, \cdots, a_r)M: \mathfrak{a}^n/(a_1, \cdots, a_r)M$

for some regular *M*-sequence a_1, \dots, a_r in a. Since $\mathfrak{a}H^r_{\mathfrak{m}}(M) = 0$, we must have

$$(a_1, \cdots, a_r)M$$
: $\mathfrak{a} = \bigcup_{n=1}^{\infty} (a_1, \cdots, a_r)M$: \mathfrak{a}^n ,

hence $H^{r}(\mathfrak{a}; M) \cong H^{r}_{\mathfrak{m}}(M)$.

Further, we can show that there exists a practical reduction process to check where a given ideal is *M*-standard.

First, we note that by Corollary 2.4, α is M/aM-standard for every element $a \in \alpha$ which forms part of a s.o.p. of M, porvided that α is Mstandard. However, the existence of such an element a does not imply (even in the case depth M > 0) that α is M-standard, see [31]. But we still have the following non-zerodivisor characterization of standard ideals in case depth M > 0:

COROLLARY 3.8 (cf. [24, Satz 6.5] or [31, Theorem]). Suppose that depth M > 0. Then α is M-standard iff α is M/aM-standard for some non-zerodivisor $a \in \alpha$ of M with one of the following two properties:

- (i) $a \in a^2$.
- (ii) $aH^i_{\mathfrak{m}}(M) = 0$ for all $i = 1, \dots, d-1$.

The case depth M = 0 can be transferred to the case depth M > 0 by the following result:

COROLLARY 3.9 (cf. [25, Theorem 4]). a is M-standard iff the following conditions are satisfied:

(i) a is \overline{M} -standard.

(ii) $(a_1, \dots, a_d)M \subset H^0_m(M) = 0$ for every d element subset $\{a_1, \dots, a_d\}$ of some M-base of \mathfrak{a} .

The proofs for Corollaries 3.8 and 3.9 (based on Theorem 3.4) are similar to the ones for [24, Satz 6.5], [25, Theorem 4]. Hence we omit them.

For the remainder of this section, let $R = \bigoplus_{n=0}^{\infty} R_n$ be a noetherian graded ring such that R_0 is a local ring. Note that with respect to the theory of graded modules, R behaves as though it were local. Then we say that a graded structure over R will have some property (C) which can be only formulated over local rings if (C) holds for the corresponded structure over R_P , where P denotes the maximal graded ideal of R. So we can use the notions of (homogeneous) generalized C-M modules, standard s.o.p.'s, standard ideals, etc. over R.

Let *E* be a finitely generated graded *R*-module with $d:=\dim E \ge 1$ and *I* a graded ideal contained in the ideal R^+ of elements of positive degree of *R* with $l(E/IE) < \infty$. Put

$$N_i := \{n; [H^i_P(E)]_n \neq 0\}$$

for $i = 0, \dots, d - 1$. Then under certain assumption on N_i , we can give a criterion for I to be a E-standard ideal.

THEOREM 3.10. Suppose that E is a generalized C-M module with

$$\max N_i \leq \min N_{i+1} + 1$$
 ,

 $i = 0, \dots, d - 2$. Then I is a E-standard ideal iff

 $IH_P^i(E) = 0$

for $i = 0, \dots, d - 1$.

For the proof of Theorem 3.10 we shall need the following

LEMMA 3.11. Let a_1, \dots, a_d be a system of homogeneous parameters of E of positive degree. Then, by the assumption of Theorem 3.10, there exists a graded homomorphism

$$\varphi_j^i: H^i_P(E|\mathfrak{q}_j E) \longrightarrow H^{i+j}_P(E)$$

of degree $t_j := -\sum_{i=1}^{j} \deg(a_i)$ which is injective in degree $> \min N_{i+j} - t_j$ for all non-negative integers i, j with i + j < d.

Proof. We go by induction on j. For j = 0 there is nothing to prove. For j > 0 we consider the exact sequence

$$0 \longrightarrow E/\mathfrak{q}_{j-1}E \colon a_j \longrightarrow E/\mathfrak{q}_{j-1}E \longrightarrow E/\mathfrak{q}_jE \longrightarrow 0 \;.$$

Note that by Lemma 1.1 (iv), $q_{j-1}E: a_j/q_{j-1}E \subseteq H^0_P(E/q_{j-1}E)$ is of finite length. Then the natural homomorphism

$$H_P^{i+1}(E/\mathfrak{q}_{j-1}E) \longrightarrow H_P^{i+1}(E/\mathfrak{q}_{j-1}E;a_j)$$

is an isomorphism. Hence we have an exact sequence

$$H^{i}_{P}(E/\mathfrak{q}_{j-1}E) \xrightarrow{\alpha} H^{i}_{P}(E/\mathfrak{q}_{j}E) \xrightarrow{\beta} H^{i+1}_{P}(E/\mathfrak{q}_{j-1}E)$$

with deg $\alpha = 0$ and deg $\beta = -\deg(a_j)$. Put

$$\varphi_j^i = \varphi_{j-1}^{i+1} \beta$$

where the existence of φ_{j-1}^{i+1} follows from the induction hypothesis. Then φ_j^i is a graded homomorphism from $H_P^i(E|\mathfrak{q}_j E)$ to $H_P^{i+j}(E)$ of degree $t_j = t_{j-1} - \deg(a_j)$. To show that φ_j^i is injective in degree $> \min N_{i+j} - t_j$, we only need to show that $[H_P^i(E|\mathfrak{q}_{j-1}E)]_n = 0$ for $n > \min N_{i+j} - t_j$. Note that

$$\min N_{i+j} - t_j \ge \max N_{i+j-1} - 1 - t_{j-1} + \deg(a_j)$$

 $\ge \max N_{i+j-1} - t_{j-1}.$

Then $[H_P^{i+j-1}(E)]_{n+t_{j-1}} = 0$ by the definition of N_{i+j-1} , hence so is $[H_P^i(E/\mathfrak{q}_j E)]_n$ as a submodule of $[H_P^{i+j-1}(E)]_{n+t_{j-1}}$ by the induction hypothesis on φ_{j-1}^i .

Proof of Theorem 3.10. It suffices to show the sufficient part. Suppose that $IH_P^i(E) = 0$ for $i = 0, \dots, d-1$. Then we want to show that every homogeneous s.o.p. a_1, \dots, a_d of E contained in I is a d-sequence of E, which then implies that I is a E-standard ideal by Proposition 3.1. By Remark 2.8 (2), we only need to show that

$$\mathfrak{q}_{i-1}E$$
: $a_i^2 \subseteq \mathfrak{q}_{i-1}E$: \mathfrak{q}

for $i = 1, \dots, d$. First, by Lemma 1.1 (iv), we have

$$\mathfrak{q}_{i-1}E\colon a_i^2/\mathfrak{q}_{i-1}E\subseteq H^0_P(E/\mathfrak{q}_{i-1}E)$$
 .

Hence the case i = 1 immediately follows from the fact $\mathfrak{q} H_P^0(E) \subseteq IH_P^0(E)$ = 0. Now let i > 1. Since I contains only elements of positive degree, from Lemma 3.11 we can easily see that via the homomorphism φ_{i-1}^0 ,

$$\mathfrak{q}[\mathfrak{q}_{i-1}E:a_i^2/\mathfrak{q}_{i-1}E]_t \subseteq I[H^0_P(E/\mathfrak{q}_{i-1}E)]_t \subseteq IH^{i-1}_P(E) = 0$$

for $t \ge \min N_{i-1} - t_{i-1}$. It remains to show that

$$[\mathfrak{q}_{i-1}E:\mathfrak{a}_i^2]_t\subseteq\mathfrak{q}_{i-1}E:\mathfrak{q}$$

for $t < \min N_{i-1} - t_{i-1}$. Let m_i be an arbitrary element of such $[q_{i-1}E:a_1^2]_t$. Then

$$a_i^2 m_i = -\sum_{j=1}^{i-1} a_j m_j$$

for some $m_j \in E$. Thus, m_1, \dots, m_i define a cycle of $K(a_1, \dots, a_{i-1}, a_i^2; E)$

$$e = \sum_{j=1}^{i} m_j X_j$$

with

$$\deg{(e)} = t - \sum_{j=1}^{i-1} \deg{(a_j)} = t + t_{i-1} < \min{N_{i-1}}$$

Note that by the proof for the sufficient part of Theorem 3.4, we have a surjective homomorphism of degree 0 from $H_P^{i-1}(E)$ onto $H_{q_i}^{i-1}(E)$. Then $H_{q_i}^{i-1}(E) = 0$ in degree $< \min N_{i-1}$. Hence there exist integers *n* such that the image of *e* in $K(a_1^n, \dots, a_i^n; E)$ is a boundary. From this it follows that

$$(a_1 \cdots a_{i-1})^{n-1} m_i \in (a_1^n, \cdots, a_{i-1}^n) E$$
.

Now, proceeding as at the end of the proof for the sufficient part of Theorem 3.4, we get

$$m_i \in (a_1^n, \cdots, a_{i-1}^n) E: (a_1 \cdots a_{i-1})^{n-1} \subseteq \mathfrak{q}_{i-1} E: \mathfrak{q},$$

as required. The proof of Theorem 3.10 is now complete.

From Theorem 3.10 we immediately get the following consequence which generalizes a well-known criterion for graded Buchsbaum rings.

COROLLARY 3.12 (cf. [8, Proposition 3.1]). Suppose that there exist integers t_0, \dots, t_{d-1} with $t_i \leq t_{i+1} + 1$, $i = 0, \dots, d-2$, such that

$$[H^i_P(E)]_n = 0$$

for $n \neq t_i$, $i = 0, \dots, d - 1$. Then R^+ is an E-standard ideal.

§4. Hilbert-Samuel functions

Throughout this section, M will be a generalized C-M module. In [27, Theorem 4.1] we showed that the Hilbert-Samuel (abbr. H-S)

function $l(M/\mathfrak{q}^{n+1}M)$ of M relative to a parameter ideal $\mathfrak{q} = (a_1, \dots, a_d)$ is bounded above by a polynomial of the form

$$\sum\limits_{i=0}^{d} {n+d-i \choose d-i} e_i(\mathfrak{q};M)$$
 ,

where $e_i(q; M)$ may be expressed explicitly in terms of a_1, \dots, a_d , and that they coincide iff a_1, \dots, a_d is a *d*-sequence of *M*. Now we shall show a similar but stronger result for generalized C-M modules.

THEOREM 4.1. Let a_1, \dots, a_d be an arbitrary s.o.p. of M. Then

$$l(M/\mathfrak{q}^{n+1}M) \leq {n+d \choose d} e(\mathfrak{q};M) + \sum_{i=1}^d \sum_{j=0}^{d-i} {n+d-i \choose d-i} {d-i-1 \choose j-1} l(H^j_\mathfrak{m}(M))$$

for all $n \ge 0$, where $\binom{d-i-1}{-1} := 0$ if $i \ne d$ and $\binom{-1}{-1} := 1$. Equality holds for some fixed n iff the following conditions are satisfied:

- (i) $q^{n+1}M \cap H^0_{\mathfrak{m}}(M) = 0.$
- (ii) a_1, \dots, a_d is a standard s.o.p. of \overline{M} .

Proof. We first consider the case depth M > 0. Let M_1 denote the factor module M/a_1M . Then we have the following exact sequence:

$$0 \longrightarrow \mathfrak{q}^{\iota+1}M; a_1/\mathfrak{q}^\iota M \longrightarrow M/\mathfrak{q}^\iota M \xrightarrow{a_1} M/\mathfrak{q}^{\iota+1}M \longrightarrow M_1/\mathfrak{q}^{\iota+1}M_1 \longrightarrow 0$$

for all $t \ge 0$. From this sequence we get

(1)
$$l(\mathfrak{q}^t M/\mathfrak{q}^{t+1}M) \leq l(M_1/\mathfrak{q}^{t+1}M_1).$$

By induction on d (we include the case d = 0 which is trivial), we may assume that

(2)
$$l(M_1/\mathfrak{q}^{t+1}M_1) \leq {\binom{t+d-1}{d-1}}e(a_2, \cdots, a_d; M_1) + \sum_{i=1}^{d-1} \sum_{j=0}^{d-i-1} {\binom{t+d-i-1}{d-i-1}} {\binom{d-i-2}{j-1}}l(H_\mathfrak{m}^j(M)).$$

Since $e(a_2, \dots, a_d; M_1) = e(q; M)$ and, by Lemma 1.7 (i),

$$l(H^{j}_{\mathfrak{m}}(M_{\mathfrak{l}})) \leq l(H^{j}_{\mathfrak{m}}(M)) + l(H^{j+1}_{\mathfrak{m}}(M)),$$

we get

NGÔ VIÊT TRUNG

$$l(\mathfrak{q}^{t}M/\mathfrak{q}^{t+1}M) \leq \binom{t+d-1}{d-1}e(\mathfrak{q};M) \\ + \sum_{i=1}^{d-1} \sum_{j=0}^{d-i-1} \binom{t+d-i-1}{d-i-1} \binom{d-i-2}{j-1} [l(H_{\mathfrak{m}}^{j}(M)) + l(H_{\mathfrak{m}}^{j+1}(M))] \\ = \binom{t+d-1}{d-1}e(\mathfrak{q};M) + \sum_{i=1}^{d} \sum_{j=0}^{d-i} \binom{t+d-i-1}{d-i-1} \binom{d-i-1}{j-1} l(H_{\mathfrak{m}}^{j}(M))$$

(we omit a detailed calculation here and below). Thus,

$$l(M/\mathfrak{q}^{n+1}M) = \sum_{i=0}^{n} l(\mathfrak{q}^{i}M/\mathfrak{q}^{i+1}M) \leq \sum_{i=0}^{n} \binom{t+d-1}{d-1} e(\mathfrak{q};M) \\ + \sum_{i=0}^{n} \sum_{i=1}^{d} \sum_{j=0}^{d-1} \binom{t+d-i-1}{d-i-1} \binom{d-i-1}{j-1} l(H^{j}_{\mathfrak{m}}(M)) \\ = \binom{n+d}{d} e(\mathfrak{q};M) + \sum_{i=1}^{d} \sum_{j=0}^{d-i} \binom{n+d-i}{j-1} \binom{d-i-1}{j-1} l(H^{j}_{\mathfrak{m}}(M)).$$

In particular, according to (3), equality for some $n \ge 0$ will imply

$$egin{aligned} l(M/\mathfrak{q}M) &= e(\mathfrak{q};M) + \sum\limits_{i=1}^d \sum\limits_{j=0}^{d-i} {d-i-1 \choose d-i-1} {d-i-1 \choose j-1} l(H_\mathfrak{m}^j(M)) \ &= e(\mathfrak{q};M) + I(M) \end{aligned}$$

by Lemma 1.5. Hence a_1, \dots, a_d is a standard s.o.p. of M.

For the case depth M = 0, we pass to \overline{M} (depth $\overline{M} > 0$) as follows:

$$\begin{split} l(M/\mathfrak{q}^{n+1}M) &= l(M/\mathfrak{q}^{n+1}M + H^{0}_{\mathfrak{m}}(M)) + l(\mathfrak{q}^{n+1}M + H^{0}_{\mathfrak{m}}(M)/\mathfrak{q}^{n+1}M) \\ &= l(\overline{M}/\mathfrak{q}^{n+1}\overline{M}) + l(H^{0}_{\mathfrak{m}}(M)/\mathfrak{q}^{n+1}M \cap H^{0}_{\mathfrak{m}}(M)) \\ (5) &= \binom{n+d}{d} e(\mathfrak{q}; \overline{M}) + \sum_{i=1}^{d} \sum_{j=0}^{d-i} \binom{n+d-i}{d-i} \binom{d-i-1}{j-1} l(H^{j}_{\mathfrak{m}}(\overline{M})) \\ &+ l(H^{0}_{\mathfrak{m}}(M)) \\ &= \binom{n+d}{d} e(\mathfrak{q}; M) + \sum_{i=1}^{d} \sum_{j=0}^{d-i} \binom{n+d-i}{d-i} \binom{d-i-1}{j-1} l(H^{j}_{\mathfrak{m}}(M)) \end{split}$$

because $e(q; \overline{M}) = e(q; M)$, $H^{\circ}_{\mathfrak{m}}(\overline{M}) = 0$, $H^{j}_{\mathfrak{m}}(\overline{M}) = H^{j}_{\mathfrak{m}}(M)$ for $j = 1, \dots, d-1$. From this proof we can easily see that equality in (5) implies the conditions (i) and (ii).

Conversely, assume that (i) and (ii) are satisfied. Then using (5), we may assume that depth M > 0. By Corollary 2.6 (v), we have

$$\mathfrak{q}^{t+1}M$$
: $a_1 = \mathfrak{q}^t M$

for all $t \ge 0$. Hence (1) is an equality. By induction, we may also assume

that (2) is an equality. Further, since by Theorem 2.5 $a_1H_m^j(M) = 0$ for all $j = 0, \dots, d-1$, we have

$$l(H^j_{\mathfrak{m}}(M_{\mathfrak{l}})) = l(H^j_{\mathfrak{m}}(M)) + l(H^{j+1}_{\mathfrak{m}}(M))$$

for $j = 0, \dots, d - 2$ by Lemma 1.7. Hence (3) is an equality too. Thus, (4) is an equality, as required.

From Corollary 2.3 and Theorem 4.1 we immediately get the following consequence which generalizes the main result of [18].

COROLLARY 4.2. a_1, \dots, a_d is a standard s.o.p. of M iff

$$l(M/\mathfrak{q}^{n+1}M) = \binom{n+d}{d} e(\mathfrak{q};M) + \sum_{i=1}^{d} \sum_{j=0}^{d-i} \binom{n+d-i}{d-i} \binom{d-i-1}{j-1} l(H_{\mathfrak{m}}^{j}(M))$$

for all $n \ge 0$.

Now we will use Theorem 4.1 to study the H-S function of an arbitrary submodule N of M with $l(M/N) < \infty$ relative to an ideal α of A with $l(M/\alpha M) < \infty$.

We shall need the following notion of [27]:

DEFINITION. a_1, \dots, a_d is called *N*-independent if every homogeneous form in *d* indeterminates over *M* vanishing at a_1, \dots, a_d has all its coefficients in *N*.

If a_1, \dots, a_d is a standard s.o.p. of M, one can use the following result to check whether a_1, \dots, a_d is N-independent:

LEMMA 4.3 [27, Corollary 3.4]. Let a_1, \dots, a_d be a d-sequence of M. Then the following conditions are equivalent:

- (i) a_1, \dots, a_d are N-independent.
- (ii) $q_{d-1}M: a_d \subseteq N$ by every permutation of a_1, \dots, a_d .

(iii)
$$l(\mathfrak{q}^n M/\mathfrak{q}^u N) = \binom{n+d-1}{d-1} l(M/N)$$
 for some (or all) $n \ge 1$.

Moreover, we call a_1, \dots, a_d a minimal reduction of a relative to N if $a_1, \dots, a_d \in a \setminus a^2$ and their initial forms in $G_a(A)$ forms a homogeneous s.o.p. of $G_a(N)$. In this case, we have

$$e(\mathfrak{q};N)=e(\mathfrak{a};N).$$

It is well-known that minimal reductions always exist if the residue field $k:=A/\mathfrak{m}$ is infinite, a hypothesis which never cause us any problem because we can replace A by the local ring $A[u]_{\mathfrak{m}[u]}$, where u is some indeterminate. See [16].

Our result concerning the H-S function of N relative to α may be formulated as follows.

PROPOSITION 4.4. Let N and α be as above. Then $l(M/\alpha^n N)$

$$egin{aligned} &\leq {n+d-1 \choose d} e(\mathfrak{a};M) + \sum\limits_{i=1}^{d} \sum\limits_{j=0}^{d-i} {n+d-i-1 \choose d-i} {d-i-1 \choose j-1} l(H_{\mathfrak{m}}^{j}(M)) \ &+ {n+d-1 \choose d-1} l(M/N+H_{\mathfrak{m}}^{\mathfrak{o}}(M)) \end{aligned}$$

for all $n \ge 1$. If k is infinite, equality holds for some fixed n iff for every or some minimal reduction a_1, \dots, a_d of a relative to N, the following conditions are satisfied:

(i)
$$q^n N = a^n N$$
.

(ii) a_1, \dots, a_d is a standard s.o.p. of \overline{M} .

(iii) $[\mathfrak{q}_{d-1}M + H^0_{\mathfrak{m}}(M)]: a_d \subseteq N + H^0_{\mathfrak{m}}(M)$ by every permutation of a_1 ,

$$\cdots, u_d$$
.

(iv) $\mathfrak{q}^n N \cap H^0_\mathfrak{m}(M) = 0.$

Proof. Without restriction we may assume that k is infinite. Then there exists a minimal reduction a_1, \dots, a_d of a relative to N. We have

(1)
$$\begin{split} l(M/\mathfrak{a}^n N) &\leq l(M/\mathfrak{q}^n N) = l(M/\mathfrak{q}^n M + H^0_\mathfrak{m}(M)) + l(\mathfrak{q}^n M + H^0_\mathfrak{m}(M)/\mathfrak{q}^n M) \\ &+ l(\mathfrak{q}^n M/\mathfrak{q}^n N + \mathfrak{q}^n H^0_\mathfrak{m}(M)) + l(\mathfrak{q}^n N + \mathfrak{q}^n H^0_\mathfrak{m}/M)/\mathfrak{q}^n. \end{split}$$

By Theorem 4.1, it is easy to verify that

(2)
$$l(M/\mathfrak{q}^{n}M + H^{0}_{\mathfrak{m}}(M)) = l(\overline{M}/\mathfrak{q}^{n}\overline{M}) \leq \binom{n+d-1}{d}e(\mathfrak{a}; M) + \sum_{i=1}^{d} \sum_{j=1}^{d-i} \binom{n+d-i-1}{d-i}\binom{d-i-1}{j-1}l(H^{j}_{\mathfrak{m}}(M))$$

Further, we have

$$\begin{aligned} &l(\mathfrak{q}^nM+H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}^nM)+l(\mathfrak{q}^nN+\mathfrak{q}^nH^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}^nN)\\ &=l(H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}^nM\cap H^{\mathfrak{o}}_{\mathfrak{m}}(M))+l(\mathfrak{q}^nH^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}^nN\cap \mathfrak{q}^nH^{\mathfrak{o}}_{\mathfrak{m}}(M))\\ &\leq l(H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}^nN\cap \mathfrak{q}^nH^{\mathfrak{o}}_{\mathfrak{m}}(M))\leq l(H^{\mathfrak{o}}_{\mathfrak{m}}(M))\ . \end{aligned}$$

Moreover, since q^n is generated by $\binom{n+d-1}{d-1}$ monomials of degree n in a_1, \dots, a_d ,

(4)
$$l(\mathfrak{q}^n M/\mathfrak{q}^n N + \mathfrak{q}^n H^{\mathfrak{o}}_{\mathfrak{m}}(M)) \leq \binom{n+d-1}{d-1} l(M/N + H^{\mathfrak{o}}_{\mathfrak{m}}(M)).$$

Hence, summing up, we get

$$egin{aligned} &l(M/\mathfrak{a}^nM)\ &\leq {n+d-1 \choose d}e(\mathfrak{a};M)+\sum\limits_{i=1}^d\sum\limits_{j=0}^{d-i}{n+d-i-1 \choose d-1}{d-i-1 \choose j-1}l(M/\mathfrak{a}^nM)\ &+{n+d-1 \choose d}l(M/N+H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathrm{m}}(M))\,. \end{aligned}$$

Equality holds above iff we have equalities in (1) to (4). Clearly, (1) is an equality iff (i) is satisfied. By Theorem 4.1, (2) is an equality iff (ii) is satisfied. (3) is an equality iff

$$(5) \qquad \qquad \mathfrak{q}^{n}M\cap H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)=\mathfrak{q}^{n}H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M) \quad \text{and} \quad \mathfrak{q}^{n}N\cap \mathfrak{q}^{n}H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)=0\,.$$

By Lemma 4.3, (4) is an equality iff (iii) is satisfied, provided that a_1 , \cdots , a_d is a standard s.o.p. of \overline{M} . Thus, to prove the last statement of Proposition 4.4, we only need to show that (5) is equivalent to (iv) under the assumption that (ii) and (iii) are already satisfied. It suffices to show that (iv) implies

$$\mathfrak{q}^n M \cap H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M) = q^n H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)$$
 .

Since a_1, \dots, a_d are $(N + H^0_m(M)/H^0_m(M))$ -independent by Lemma 4.3, we first have

$$\mathfrak{q}^n M \cap H^{\scriptscriptstyle 0}_{\mathfrak{m}}(M) = \mathfrak{q}^n (N + H^{\scriptscriptstyle 0}_{\mathfrak{m}}(M)) \cap H^{\scriptscriptstyle 0}_{\mathfrak{m}}(M)$$
 .

Hence, applying (iv), we get $q^n M \cap H^0_m(M) = q^n H^0_m(M)$, as required. The proof of Proposition 4.4 is now complete.

COROLLARY 4.5. Suppose that the inequality of Proposition 4.4 is an equality for some $n \ge 1$. Then α is a standard ideal of \overline{M} .

Proof. By Theorem 3.4, we may assume that k is an infinite field. Then there exists a generating set S for α such that every d element subset of S forms a minimal reduction of α relative to N. Hence, applying Proposition 3.2 and Proposition 4.4, we get the statement.

From Proposition 4.4 we get the following estimation of the H-S function of M relative to α :

COROLLARY 4.6 (cf. [26, Lemma 1.1]). Let $r \ge 0$ and $s \ge 1$ be arbitrary integers. Then $l(M/a^{ns+r}M)$

$$\begin{split} & \leq {n+d-1 \choose d} s^{\scriptscriptstyle d} e(\mathfrak{a};M) + \sum_{i=1}^{d} \sum_{j=0}^{d-i} {n+d-i-1 \choose d-i} {d-i-1 \choose j-1} l(H_{\mathfrak{m}}^{\scriptscriptstyle j}(M)) \\ & + {n+d-1 \choose d-1} l(M/\mathfrak{a}^{\scriptscriptstyle r}M + H_{\mathfrak{m}}^{\scriptscriptstyle 0}(M)) \end{split}$$

for all $n \ge 1$. Moreover, if r > s, the inequality is proper.

Proof. For the first statement, we only need to replace α and N of Proposition 4.4 by α^s and $\alpha^r M$. If r > s, equality can not happen. Otherwise, we have

$$\mathfrak{q}_{d-1}M\subseteq (\mathfrak{q}_{d-1}M+H^0_\mathfrak{m}(M))\colon a_d\subseteq \mathfrak{a}^rM+H^0_\mathfrak{m}(M)$$

for every minimal reduction a_1, \dots, a_d of α^s relative to $\alpha^r M$ by Proposition 4.4 (iii). Since we may assume that k is infinite, there exists a generating set S for α^s such that every d element subset of S forms a minimal reduction of α^s relative to $\alpha^r M$. Hence we must have

$$\mathfrak{a}^{s}M\subseteq\mathfrak{a}^{r}M+H^{\mathfrak{o}}_{\mathfrak{m}}(M)\subseteq\mathfrak{m}\mathfrak{a}^{s}M+H^{\mathfrak{o}}_{\mathfrak{m}}(M)$$
,

which then implies that $\alpha^s M = H^0_{\mathfrak{m}}(M)$, a contradiction to the assumption $d \ge 1$.

Corollary 4.6 has the following interesting consequence which may be used to study the relationship between degree, genus, and local cohomology of a projective curve.

COROLLARY 4.7. Let M be a two-dimensional generalized C-M module. Let $H(n) = l(M/\alpha M^{n+1})$ denote the Hilbert-Samuel polynomial of M with respect to α . Then

$$H(n)+l(H^1_{\mathfrak{m}}(M))-l(H^0_{\mathfrak{m}}(M))\geqq 0$$

for all integers n. Moreover, if n < 0, the inequality is proper.

Proof. Put

$$H(n):=rac{n(n+1)}{2}e_0+ne_1+e_2.$$

Note that

$$egin{aligned} l(M/\mathfrak{a}^rM+H^{\mathfrak{o}}_{\mathfrak{m}}(M))&=l(M/\mathfrak{a}^rM)-l(\mathfrak{a}^rM+H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{a}^rM)\ &=l(M/\mathfrak{a}^rM)-l(H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{a}^rM\cap H^{\mathfrak{o}}_{\mathfrak{m}}(M))\ &=H(r)-l(H^{\mathfrak{o}}_{\mathfrak{m}}(M)) \end{aligned}$$

for r sufficiently large. Then, using Corollary 4.6, we have

$$egin{aligned} &rac{(ns+r)(ns+r+1)}{2}e_{\scriptscriptstyle 0}+(ns+r)e_{\scriptscriptstyle 1}+e_{\scriptscriptstyle 2}\ &\leq rac{n(n+1)}{2}s^{\scriptscriptstyle 2}e_{\scriptscriptstyle 0}+nl(H^{\scriptscriptstyle 1}_{\scriptscriptstyle
m m}(M))+l(H^{\scriptscriptstyle 0}_{\scriptscriptstyle
m m}(M))\ &+(n+1)\Big[rac{r(r+1)}{2}e_{\scriptscriptstyle 0}+re_{\scriptscriptstyle 1}+e_{\scriptscriptstyle 2}-l(H^{\scriptscriptstyle 0}_{\scriptscriptstyle
m m}(M))\Big] \end{aligned}$$

for arbitrary s, $n \ge 1$. From this it follows, by elementary computation, that

$$rac{(r-s)(r-s+1)}{2}e_{_0}+(r-s)e_{_1}+e_{_2}+l(H^{_1}_{_{\mathfrak{m}}}(M))-l(H^{_0}_{_{\mathfrak{m}}}(M))\geqq 0\,.$$

Since r - s can take any value, we get the statement.

For n = 1, the inequality of Proposition 4.4 yields

$$l(M/\mathfrak{a}N) \leqq e(\mathfrak{a}\,;\,M) + I(M) + dl(M/N + H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathrm{m}}(M))\,.$$

From this it follows, for M = A and N = a = m, that

$$l(\mathfrak{m}/\mathfrak{m}^2) \leq e(\mathfrak{m}; A) + I(A) + d - 1$$

which gives a bound for the embedding dimension of generalized C-M rings, cf. [1], [17], [26]. If this bound is attained, we call A a local ring of maximal embedding dimension. J. Sally [17] and S. Goto [8] have found that C-M and Buchsbaum local rings of maximal embedding dimension behave well. So we want to extend their results for generalized C-M modules.

Our starting point is the following:

PROPOSITION 4.8. Let k be an infinite field. Then

 $l(M/\mathfrak{a}N) = e(\mathfrak{a}; M) + I(M) + dl(M/N)$

iff for some or every minimal reduction a_1, \dots, a_d of a relative to N, the following conditions are satisfied:

- (i) qN = aN.
- (ii) a_1, \dots, a_d is a standard s.o.p. of M.
- (iii) $q_{d-1}M: a_d \subseteq N$ by every permutation of a_1, \dots, a_d .

Proof. (\Rightarrow) By the inequality of Proposition 4.4, we must have $H^{\circ}_{\mathfrak{m}}(M) \subset N$. Hence, by the conditions for equality of Proposition 4.4, we only need to show (ii). Since a_1, \dots, a_d is already a standard s.o.p. of \overline{M} , by Corollary 2.3, it suffices to show that $qM \cap H^{\circ}_{\mathfrak{m}}(M) = 0$. Note that a_1, \dots, a_e are $(N/H^{\circ}_{\mathfrak{m}}(M))$ -independent by Lemma 4.3. Then we have

$$\mathfrak{q}M\cap H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathrm{m}}(M)=\mathfrak{q}N\cap H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathrm{m}}(M)=0$$

by Proposition 4.4 (iv).

(\Leftarrow) By Corollary 2.6 (iv), we have

$$H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathrm{m}}(M)=0_{\scriptscriptstyle M}\colon a_{\scriptscriptstyle d}\subseteq \mathfrak{q}_{\scriptscriptstyle e-1}M\colon a_{\scriptscriptstyle d}\subseteq N$$
 .

Hence the conclusion follows from Proposition 4.4 by using Corollary 2.3.

COROLLARY 4.9. Suppose that

$$l(M/\alpha N) = e(\alpha; M) + I(M) + dl(M/N).$$

Then the following statements holds:

(i)
$$l(M/a^n N) = \binom{n+d-1}{d} e(a; M) + \sum_{i=1}^{d} \sum_{j=0}^{d-i} \binom{n+d-i-1}{d-i} \binom{d-i-1}{d-1} l(H_{\mathfrak{m}}^j(M)) + \binom{n+d-1}{d-1} l(M/N)$$

for all $n \geq 0$.

(ii) α is a standard ideal of M and N.

Proof. Without restriction we may assume that k is infinite. Note that $H^{0}_{\mathfrak{m}}(M) \subset N$. Then (i) can be easily deduced from Proposition 4.4. Since there exists a generating set S for \mathfrak{a} such that every d element subset of S forms a minimal reduction of \mathfrak{a} relative to N, \mathfrak{a} is M-standard by Proposition 4.8 (ii) and Proposition 3.2. To show that \mathfrak{a} is N-standard, we only need to show that every minimal reduction a_1, \dots, a_d of \mathfrak{a} relative to N is a standard s.o.p. of N. Note that $\mathfrak{q}N = \mathfrak{a}N$ by Proposition 4.8 (i). Then

$$\begin{split} I(q; N) &= l(M/qN) - l(M/N) - e(q; M) \\ &= l(M/aN) - l(M/N) - e(a; M) \\ &= I(M) + (d-1)l(M/N) \,. \end{split}$$

To compute I(N) we consider the exact sequence

 $0 \longrightarrow N \longrightarrow M \longrightarrow M/N \longrightarrow 0.$

Note that

$$H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(N)=N\cap H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)=H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)$$
 .

Then from the above exact sequence we get the exact sequence

$$0 \longrightarrow M/N \longrightarrow H^1_{\mathfrak{m}}(N) \longrightarrow H^1_{\mathfrak{m}}(M) \longrightarrow 0.$$

Thus, since $H^i_{\mathfrak{m}}(N) \cong H^i_{\mathfrak{m}}(M)$ for $i \ge 2$, using Lemma 1.5 we get

$$\begin{split} I(N) &= \sum_{i=0}^{d-1} \binom{d-1}{i} l(H^i_{\mathfrak{m}}(N)) = \sum_{i=0}^{d-1} \binom{d-1}{i} l(H^i_{\mathfrak{m}}(M)) + (d-1)l(M/N) \\ &= I(M) + (d-1)l(M/N) = I(\mathfrak{q};N) \,. \end{split}$$

Hence a_1, \dots, a_d is a standard s.o.p. of N, as required.

In particular, if

$$l(M/\mathfrak{a}^{2}M) = e(\mathfrak{a};M) + I(M) + dl(M/\mathfrak{a}M)$$
,

Corollary 4.9 (i) gives an explicit formula for $l(M/a^{n+1}M)$ (by replacing N by aM), which recovers all known results on H-S functions of C-M and Buchsbaum local rings of maximal embedding dimension, cf. [8] and [17].

It should be pointed out that there do not exist generalized C-M non-Buchsbaum rings of maximal embedding dimension. This fact follows from the following consequence of Corollary 4.9 (ii):

COROLLARY 4.10. Suppose that

$$l(M/\mathfrak{m}N) = e(\mathfrak{m}; M) + I(M) + dl(M/N)$$
.

Then M and N are Buchsbaum modules.

EXAMPLE. Let a_1, \dots, a_d be a standard s.o.p. of M, then

$$l(M/\mathfrak{a}N) = e(\mathfrak{a}; M) + I(M) + dl(M/N)$$

for any module $N \supseteq qM + \sum_{i=1}^{d} (a_1, \dots, a_i, \dots, a_d) M: a_i$ and any ideal a such that $q \subseteq a \subseteq qN: N$. For, we have qN = aN, hence e(q; N) = e(a; N) or, equivalently, e(q; M) = e(a; M) which we really need in the proof of Proposition 4.8 for the above equality instead of the assumption that a_1, \dots, a_d is a minimal reduction of a relative to N.

§5. Associated graded modules

In this section, we will study when the associated graded module

$$G_{\mathfrak{a}}(M) := \bigoplus_{n=0}^{\infty} \mathfrak{a}^n M / \mathfrak{a}^{n+1} M$$

of M relative to an ideal α of A with $l(M/\alpha M) < \infty$ is a graded generalized C-M module over $G_{\alpha}(A)$.

We shall denote by a^* the initial form of an element a of A in $G_a(A)$, i.e. the image of a in a^n/a^{n+1} where n is the largest integer such that $a \in a^n$.

We start with the following result which is originally due to S. Goto $[10, \S 3]:$

LEMMA 5.1. Let a_1, \dots, a_d be a minimal reduction of α relative to M. Let n_1, \dots, n_d be arbitrary positive integers. Then

$$I(a_{\scriptscriptstyle 1}^{st n_{\scriptscriptstyle 1}},\,\cdots,\,a_{\scriptscriptstyle d}^{st n_{\scriptscriptstyle d}};\,G_{\scriptscriptstyle a}(M)) \geqq I(a_{\scriptscriptstyle 1}^{n_{\scriptscriptstyle 1}},\,\cdots,\,a_{\scriptscriptstyle d}^{n_{\scriptscriptstyle d}};\,M)$$
 .

Equality holds iff

$$\mathfrak{a}^n M \cap (a_1^{n_1}, \, \cdots, \, a_d^{n_d}) M = \sum\limits_{i=1}^d a_i^{n_i} \mathfrak{a}^{n-n_i} M$$

for all $n \ge 0$, where we set $a^m = A$ if m < 0.

Proof. We have

$$\begin{split} l(G_{\mathfrak{a}}(M)/(a_{1}^{*n_{1}},\cdots,a_{d}^{*n_{d}})G_{\mathfrak{a}}(M)) &= \sum_{n=0}^{\infty} l\left(\mathfrak{a}^{n}M \big/ \sum_{i=1}^{d} a_{i}^{n_{i}}\mathfrak{a}^{n-n_{i}}M + \mathfrak{a}^{n+1}M\right) \\ &\geq \sum_{n=0}^{\infty} l(\mathfrak{a}^{n}M/\mathfrak{a}^{n}M \cap (a_{1}^{n_{1}},\cdots,a_{d}^{n_{d}})M + \mathfrak{a}^{n+1}M) \\ &= \sum_{n=0}^{\infty} l((a_{1}^{n_{1}},\cdots,a_{d}^{n_{d}})M + \mathfrak{a}^{n}M/(a_{1}^{n_{1}},\cdots,a_{d}^{n_{d}})M + \mathfrak{a}^{n+1}M) \\ &= l\left(M \big/ \bigcap_{n=0}^{\infty} ((a_{1}^{n_{1}},\cdots,a_{d}^{n_{d}})M + \mathfrak{a}^{n+1}M)\right) = l(M/(a_{1}^{n_{1}},\cdots,a_{d}^{n_{d}})M) \,. \end{split}$$

Note that

$$e(a_1^{*n_1}, \cdots, a_d^{*n_d}; G_{\mathfrak{a}}(M)) = n_1 \cdots n_d e(a_1^*, \cdots, a_d^*; G_{\mathfrak{a}}(M))$$

 $= n_1 \cdots n_d e(\mathfrak{a}; M) = e(a_1^{n_1}, \cdots, a_d^{n_d}; M).$

Then we get

(1)
$$I(a_1^{*n_1}, \dots, a_d^{*n_d}; G_a(M)) \ge I(a_1^{n_1}, \dots, a_d^{n_d}; M)$$
,

which will be an equality if

(2)
$$\mathfrak{a}^n M \cap (a_1^{n_1}, \cdots, a_d^{n_d}) M = \sum_{i=1}^d a_i^{n_i} \mathfrak{a}^{n-n_i} M.$$

Conversely, assume that (1) is an equality. Then we must have

$$\mathfrak{a}^n M \cap (a_1^{n_1}, \cdots, a_d^{n_d}) M \subseteq \sum_{i=1}^d a_i^{n_i} \mathfrak{a}^{n-n_i} M + \mathfrak{a}^{n+1} M$$

for all $n \ge 0$. Hence

$$\mathfrak{a}^n M \cap (a_1^{n_1}, \cdots, a_d^{n_d}) M = \sum_{i=1}^d a_i^{n_i} \mathfrak{a}^{n-n_i} M + \mathfrak{a}^{n+1} M \cap (a_1^{n_1}, \cdots, a_d^{n_d}) M$$
 $\subseteq \sum_{i=1}^d a_i^{n_i} \mathfrak{a}^{n-n_i} M + \mathfrak{a}^{n+2} M \subseteq \cdots \subseteq$
 $\subseteq \bigcap_{m=n+1}^\infty \left(\sum_{i=1}^d a_i^{n_i} \mathfrak{a}^{n-n_i} M + \mathfrak{a}^m M \right) = \sum_{i=1}^d a_i^{n_i} \mathfrak{a}^{n-n_i} M ,$

which then implies (2), as required.

From Lemma 5.1 we can conclude that the property of being a generalized C-M module is transferred from $G_{a}(M)$ to M.

COROLLARY 5.2 [10, Proposition 3.1]. Suppose that $G_{a}(M)$ is a generalized C-M module. Then so is M with $I(M) \leq I(G_{a}(M))$.

Proof. Without restriction we may assume that k is an infinite field. Then we can find a minimal reduction a_1, \dots, a_d of a relative to M. By Lemma 5.1, we have

$$I(a_1^{n_1},\,\cdots,\,a_d^{n_d};M) \leqq I(G_{\mathfrak{a}}(M))$$

for all positive integers n_1, \dots, n_d . Hence *M* is a generalized C-M module with $I(M) \leq I(G_a(M))$ by Lemma 1.1 (iii) and Lemma 1.5.

In general, it is hard to find conditions for the converse of Corollary 5.2. We can only prove this converse if α is generated by a standard s.o.p. of M or if $l(M/\alpha^2 M)$ attains some extreme value.

First, we will exhibit some properties of d-sequences (hence of standard s.o.p.'s) related to this topic.

LEMMA 5.3 (see e.g. [27, § 3]). Let a_1, \dots, a_d be a d-sequence of M. Then

(i) $G_{\mathfrak{q}}(M)/(a_1^*, \cdots, a_i^*)G_{\mathfrak{q}}(M) \cong G_{\mathfrak{q}}(M/\mathfrak{q}_iM), \ i = 1, \cdots, d-1.$

(ii) $G_{\mathfrak{q}}(M) \cong S_{\mathfrak{q}}(M)/\mathfrak{q}S_{\mathfrak{q}}(M)$, where $S_{\mathfrak{q}}(M)$ denotes the symmetric module of M with respect to \mathfrak{q} .

Now we are ready to investigate the associated graded module $G_{\mathfrak{q}}(M)$ of a standard parameter ideal \mathfrak{q} of M. We will denote by P the maximal graded ideal of $G_{\mathfrak{q}}(A)$.

THEOREM 5.4 (cf. [4, (10.1)] and [9, Theorem 1.1]). Let a_1, \dots, a_a be a standard s.o.p. of M. Then $G_a(M)$ is a generalized C-M module with

$${H}^i_{\scriptscriptstyle P}(G_{\scriptscriptstyle \mathfrak{a}}(M))={H}^i_{\scriptscriptstyle \mathfrak{m}}(M)(i)$$

for $i = 0, \dots, d - 1$, where $H^i_{\mathfrak{m}}(M)$ is considered as a graded module concentrated in degree 0 (the integer in the round brackets denotes the shifting degree), and $[H^d_P(G_{\mathfrak{q}}(M))]_n = 0$ for n > -d.

Proof. Note that $\mathfrak{q}M \cap H^{\mathfrak{o}}_{\mathfrak{m}}(M) = 0$ by Corollary 2.3. Then

$$egin{aligned} & [G_{\mathfrak{q}}(\overline{M})]_n = \mathfrak{q}^n M + H^{\mathfrak{o}}_{\mathfrak{m}}(M)/\mathfrak{q}^{n+1}M + H^{\mathfrak{o}}_{\mathfrak{m}}(M) \cong \mathfrak{q}^n M/\mathfrak{q}^n M \cap H^{\mathfrak{o}}_{\mathfrak{m}}(M) + \mathfrak{q}^{n+1}M \ &= \mathfrak{q}^n M/\mathfrak{q}^{n+1}M = [G_{\mathfrak{q}}(M)]_n \end{aligned}$$

for all n > 0. Hence we have the exact sequence

(1)
$$0 \longrightarrow H^0_{\mathfrak{m}}(M) \longrightarrow G_{\mathfrak{q}}(M) \longrightarrow G_{\mathfrak{q}}(\overline{M}) \longrightarrow 0 .$$

Now, it is clear that we only need to prove the statement for \overline{M} , i.e. we may assume that depth M > 0. In this case, using Corollary 2.6 (v), we have

$$[0_{{}_{G_q(M)}} \colon a_1^*]_n = \mathfrak{q}^n M \cap (\mathfrak{q}^{n+2}M; a_1)/\mathfrak{q}^{n+1}M = 0$$

for all $n \ge 0$. Therefore, a_1^* is a non-zerodivisor of $G_{\mathfrak{q}}(M)$. Hence $H^{\mathfrak{g}}_{\mathcal{P}}(G_{\mathfrak{q}}(M)) = 0$. Moreover, we have the exact sequence

(2)
$$0 \longrightarrow G_{\mathfrak{q}}(M) \xrightarrow{a_1^*} G_{\mathfrak{q}}(M) \longrightarrow G_{\mathfrak{q}}(M) / a_1^* G_{\mathfrak{q}}(M) \longrightarrow 0 .$$

Note that by Lemma 5.2 (i),

$$G_{\mathfrak{q}}(M)/a_1^*G_{\mathfrak{q}}(M)\cong G_{\mathfrak{q}}(M/a_1M)$$
 .

If d = 1, $G_{q}(M/a_{1}M) = M/a_{1}M$. Hence from (2) we get

$$[H^1_P(G_q(M))]_n \xrightarrow{a_1^*} [H^1_P(G_q(M))]_{n+1}$$

for all $n \ge 0$. Since every element of $H^1_P(G_q(M))$ is annihilated by some power of a_1^* , we must have $[H^1_P(G_q(M))]_n = 0$ for all $n \ge 0$. So we have proved the case d = 1. If d > 1, by induction we may assume that

$$H^i_P(G_{\mathfrak{a}}(M/a_1M))=H^i_{\mathfrak{m}}(M/a_1M)(i)$$

for $i = 0, \dots, d-2$, and $[H_P^{d-1}(G_q(M/a_1M))]_n = 0$ for n > 1 - d. Then from (2) we can deduce that

$$[H^i_P(G_q(M))]_n \xrightarrow{a_1^*} [H^i_P(G_q(M))]_{n+1}$$

and, therefore, $[H_P^i(G_q(M))]_n = 0$ for all n > -i, $i = 1, \dots, d$. For n = -i, $i = 1, \dots, d - 1$, we may assume, by induction, that there exist isomorphisms δ_{i-1} and ε_{i-1} which make the following diagram commutative:

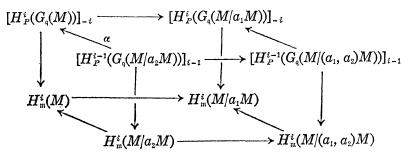

$$\begin{array}{cccc} 0 \longrightarrow [H_{P}^{i-1}(G_{\mathfrak{q}}(M))]_{1-i} \longrightarrow [H_{P}^{i-1}(G_{\mathfrak{q}}(M/a_{1}M))]_{1-i} \longrightarrow [H_{P}^{i}(G_{\mathfrak{q}}(M))]_{-i} \longrightarrow 0 \\ (3) & & & & & & & \\ 0 \longrightarrow H_{\mathfrak{m}}^{i-1}(M) \longrightarrow H_{\mathfrak{m}}^{i-1}(M/a_{1}M) \longrightarrow H_{\mathfrak{m}}^{i}(M) \longrightarrow 0 \end{array}$$

where the short exactness of the lower sequence follows from the fact $a_1H_{\mathfrak{m}}^{i-1}(M) = a_1H_{\mathfrak{m}}^i(M) = 0$ of Theorem 2.5, and δ_i is the induced isomor-

phism. It remains to show, for the induction proof, that the diagram

(4)
$$\begin{array}{c} [H^{i}_{P}(G_{q}(M))]_{-i} \longrightarrow [H^{i}_{P}(G_{q}(M/a_{1}M)]_{-i} \\ & \downarrow^{\delta_{i}} \qquad \qquad \downarrow^{\varepsilon_{i}} \\ H^{i}_{\mathfrak{m}}(M) \longrightarrow H^{i}_{\mathfrak{m}}(M/a_{1}M) \end{array}$$

is commutative. For that we consider the following cubic diagram:

where the top face is derived from the commutative diagram

$$\begin{array}{ccc} G_{\mathfrak{q}}(M) & \longrightarrow & G_{\mathfrak{q}}(M)/a_{1}^{*}G_{\mathfrak{q}}(M) \\ & & & \downarrow \\ & & & \downarrow \\ & & & G_{\mathfrak{q}}(M)/a_{2}^{*}G_{\mathfrak{q}}(M) & \longrightarrow & G_{\mathfrak{q}}(M)/(a_{1}^{*}, a_{2}^{*})G_{\mathfrak{q}}(M) \end{array}$$

by using Lemma 5.3 (i). The commutativity of the left face has been shown in (3) by replacing a_1 by a_2 . By induction we may also assume that the front and right faces are commutative (the assumption depth M > 0 does not cause us any problem because (1)). That the bottom face is commutative is immediate. Thus, since α is surjective by virtue of (3), we can conclude that the back face, i.e. (4), is commutative too. So we have proved that

$$[H^i_P(G_q(M))]_{-i} \cong H^i_m(M).$$

For n = 1 - i, we consider the commutative diagram

Then we can see that $[H^i_P(G_q(M))]_{1-i} = 0$. For n < 1 - i, we have

$$[H^i_P(G_q(M))]_n \cong [H^i_P(G_q(M))]_{n+1}$$

by (2) and the induction hypothesis on M/a_1M . Hence

$$[H^{i}_{P}(G_{q}(M))]_{n} \cong [H^{i}_{P}(G_{q}(M))]_{1-i} = 0,$$

as required. The proof of Theorem 5.4 is now complete.

Theorem 5.4 has some interesting consequences. First, we can show that the property of being a standard s.o.p. is reserved between M and $G_{a}(M)$ in the following sense:

COROLLARY 5.5. a_1, \dots, a_d is a standard s.o.p. of M iff a_1^*, \dots, a_d^* is a standard s.o.p. of $G_q(M)$.

Proof. (\Rightarrow) follows from Corollary 3.12 and Theorem 5.4. For (\Leftarrow) we know, by Corollary 5.2, that *M* is a generalized C-M module with

$$I(M) \leq I(G_{\mathfrak{a}}(M)) = I(a_1^*, \cdots, a_d^*; G_{\mathfrak{a}}(M)) = I(\mathfrak{q}; M) \leq I(M)$$

Therefore, we must have I(q; M) = I(M).

Moreover, we have the following property of powers of standard parameter ideals:

COROLLARY 5.6 (cf. [9, Corollary 1.2]). Let a_1, \dots, a_d be a standard s.o.p. of M. Then

$$(a_1^{n_1},\,\cdots,\,a_d^{n_d})M\cap \mathfrak{q}^nM=\sum\limits_{i=1}^da_i^{n_i}\mathfrak{q}^{n-n_i}M$$

for all positive integers n_1, \dots, n_d and $n \ge 0$.

Proof. By Lemma 1.5 and Theorem 5.4, we have $I(G_q(M)) = I(M)$. By Corollary 3.3 and Corollary 5.5, $a_1^{*n_1}, \dots, a_d^{*n_d}$ and $a_1^{n_1}, \dots, a_d^{n_d}$ are standard s.o.p.'s $G_q(M)$ and M, respectively. Hence

$$I(a_1^{*n_1},\,\cdots,\,a_d^{*n_d};\,G_{\scriptscriptstyle ext{
m q}}(M))=I(a_1^{n_1},\,\cdots,\,a_d^{n_d};\,M)\,,$$

which then implies the statement by Lemma 5.1.

Now, we will give a criterion for an irrelevant graded ideal of $G_{\mathfrak{q}}(M)$ to be $G_{\mathfrak{q}}(M)$ -standard.

THEOREM 5.7. Let a_1, \dots, a_d be an arbitrary s.o.p. of M. Let $\alpha \supseteq q$ be an ideal of A. Let α^* denote the ideal of $G_q(A)$ generated by the initial forms of the elements of α . Then α^* is $G_q(M)$ -standard iff the following conditions are satisfied:

- (i) a_1, \dots, a_d is a standard s.o.p. of M.
- (ii) $\mathfrak{q}_{d-1}M$: $a_d \subseteq \mathfrak{q}_{d-1}M$: \mathfrak{a} by every permutation of a_1, \dots, a_d .

Proof. (\Rightarrow) (i) follows from Corollary 5.5. For (ii) it suffices to show that $\alpha H^0_{\mathfrak{m}}(M/\mathfrak{q}_{d-1}M) = 0$. Since a_d is a standard s.o.p. of $M/\mathfrak{q}_{d-1}M$ by Corollary 2.4, we have

$$H^0_{\mathfrak{m}}(M/\mathfrak{q}_{d-1}M) = H^0_P(G_q(M/\mathfrak{q}_{d-1}M))$$

by Theorem 5.4. But

$$G_{\mathfrak{q}}(M/\mathfrak{q}_{d-1}M) \cong G_{\mathfrak{q}}(M)/(a_1^*, \cdots, a_{d-1}^*)G_{\mathfrak{q}}(M)$$

by Lemma 5.3 (i). Hence, from the fact that

$$\mathfrak{a}^{*}H^{\scriptscriptstyle 0}_{\scriptscriptstyle P}(G_{\scriptscriptstyle \mathfrak{q}}(M)/(a_{\scriptscriptstyle 1}^{*},\,\cdots,\,a_{d-1}^{*})G_{\scriptscriptstyle \mathfrak{q}}(M)=0$$

 $(a_1^*, \dots, a_d^* \text{ is a } \mathfrak{a}^*\text{-weak } G_{\mathfrak{q}}(M)\text{-sequence by Proposition 3.1})$, we can easily conclude that $\mathfrak{a}H^0_{\mathfrak{m}}(M/\mathfrak{q}_{d-1}M) = 0$.

(\Leftarrow) From (i) and Theorem 5.4 we get $H^0_P(G_q(M)) \cong H^0_m(M)$, where $H^0_m(M)$ is considered as a graded module concentrated in degree 0. Thus, if d = 1, we have $\mathfrak{a}^*H^0_P(G_q(M)) = 0$ because $\mathfrak{a}H^0_m(M) = 0$ by (ii). Hence \mathfrak{a}^* is $G_q(M)$ -standard by Theorem 2.4. For d > 1, we first consider the case depth M > 0.

In this case, a_1^* is a non-zerodivisor of $G_q(M)$. Further, by induction, we may assume that a^* is $G_q(M/a_1M)$ -standard. Note that

$$G_{\mathfrak{q}}(M/a_1M) \cong G_{\mathfrak{q}}(M)/a_1^*G_{\mathfrak{q}}(M)$$

by Lemma 5.3 (i) and that

$$a_1^*H^i_P(G_{\mathfrak{a}}(M))=0$$

by Theorem 5.4. Then α^* is $G_{\mathfrak{q}}(M)$ -standard by Corollary 3.8.

For the case depth M = 0, we first note that

$$G_{\mathfrak{q}}(M)/H^{\mathfrak{o}}_{P}(G_{\mathfrak{q}}(M))\cong G_{\mathfrak{q}}(\overline{M})$$

by the proof of Theorem 5.4. By Corollary 2.3, a_1, \dots, a_d is still a standard s.o.p. of \overline{M} . Moreover, using Corollary 2.6 (iv), we also have

$$(\mathfrak{q}_{d-1}M + H^0_\mathfrak{m}(M))$$
: $a_d \subseteq \bigcup_{n=1}^{\infty} \mathfrak{q}_{d-1}M$: $m^n = \mathfrak{q}_{d-1}M$: $a_d \subseteq q_{d-1}M$: \mathfrak{a}
 $\subseteq (q_{d-1}M + H^0_\mathfrak{m}(M))$: \mathfrak{a} .

Hence \mathfrak{a}^* is $G_{\mathfrak{q}}(\overline{M})$ -standard by the above proof for the case depth M < 0. Now, by Corollary 3.9, it remains to find a $G_{\mathfrak{q}}(M)$ -base S for \mathfrak{a}^* such that for every d element subset $\{f_1, \dots, f_d\}$ of S,

$$(f_1, \cdots, f_d)G_{\mathfrak{a}}(M) \cap H^{\mathfrak{o}}_P(G_{\mathfrak{a}}(M)) = 0$$
.

Of course, we may assume that the residue field k is infinite. Since $a^*/Pa^* = a/\mathfrak{m}a \oplus \mathfrak{q}/\mathfrak{m}\mathfrak{q}$, we can find a $G_\mathfrak{q}(M)$ -base S for a^* such that every element $f \in S$ has the form $b^* + c^*$ for some $b \in \mathfrak{a}$, $c \in \mathfrak{q}\setminus\mathfrak{m}\mathfrak{q}$. Let $b_1^* + c_1^*$, \cdots , $b_d^* + c_d^*$ be d elements of S. Note that

$$(b_i^* + c_i^*)^n \in c_i^*G_{\mathfrak{q}}(M)$$

for all $i = 1, \dots, d$, *n* large. Then c_1^*, \dots, c_d^* also form a s.o.p. of $G_{\mathfrak{q}}(M)$. From this it follows that

$$(c_1^*, \cdots, c_d^*)G_{\mathfrak{q}}(A) = (a_1^*, \cdots, a_d^*)G_{\mathfrak{q}}(M)$$
 .

Hence we can write

$$c_i = \sum_{j=1}^d c_{ij} a_j + d_i$$

for some units c_{ij} of A and $d_i \in mq$, $i = 1, \dots, d$, such that det (a_{ij}) is a unit of A. Now, by Lemma 5.3 (ii), we will represent $G_q(M)$ as $S_q(M)/qS_q(M)$. If we denote by A[X] the polynomial ring over A in d indeterminates X_1, \dots, X_d , then $S_q(M)$ is defined to be the factor of $M[X] = M \bigotimes_A A[X]$ by the submodule F generated by all elements $m_1X_1 + \dots + m_dX_d$ such that $a_1m_1 + \dots + a_dm_d = 0$. Hence

$$G_{\mathfrak{q}}(M) = M[X]/\mathfrak{q}M[X] + F.$$

Put

$$Y_{i} = \sum\limits_{j=1}^{d} c_{ij} X_{j} + d_{i} + b_{i}$$
 ,

 $i = 1, \dots, d$. Then $A[X] = A[Y_1, \dots, Y_d]$. Further, using (ii) we can easily verify that

$$F \subseteq (Y_1, \cdots, Y_d, \mathfrak{q})M[X]$$
.

Let g be an arbitrary element of $(b_1^* + c_1^*, \dots, b_d^* + c_d^*)G_q(M) \cap H_P^0(G_q(M))$. Note that $H_P^0(G_q(M)) \cong H_m^0(M)$. Then we can find a representative h of g in $(Y_1, \dots, Y_d, q)M[X] \cap H_m^0(M)$. Since Y_1, \dots, Y_d may be considered as indeterminates over A, we must have $h \in qM \cap H_m^0(M) = 0$ by Corollary 2.3. Hence g = 0, as required. The proof of Theorem 5.7 is now complete.

Remark 5.8. From the above proof one can easily verify that the conditions of Theorem 5.7 may be replaced by the condition

$$\mathfrak{a} H^i_{\mathfrak{m}}(M/\mathfrak{q}_j M) = 0$$

for all non-negative integers i, j with i + j < d and every permutation of a_1, \dots, a_d . In particular, that is always satisfied if α is a standard ideal of M.

Concerning the theory of Buchsbaum modules we have the following interesting consequences:

COROLLARY 5.9. M is a Buchsbaum module iff so is $G_q(M)$ for every parameter ideal q of M.

Proof. Straightforward.

COROLLARY 5.10. *M* is a quasi-Buchsbaum module, i.e. $\mathfrak{m}H^{i}_{\mathfrak{m}}(M) = 0$ for $i = 0, \dots, d-1$, iff $G_{\mathfrak{q}}(M)$ is a Buchsbaum module for some parameter ideal \mathfrak{q} of *M*.

Proof. (\Rightarrow) follows from Theorem 5.7 and the fact that every s.o.p. of M contained in large powers of m is standard and m-weak [20]. For (\Leftarrow) we first note that a_1, \dots, a_d is a standard s.o.p. of M by Corollary 5.5. Thus, we can apply Theorem 5.4 to show that $\mathfrak{m}H^i_{\mathfrak{m}}(M) = 0$ by using the fact $PH^i_P(G_{\mathfrak{q}}(M)) = 0$, $i = 0, \dots, d-1$.

Now we will study $G_{a}(M)$ in the case $l(M/\alpha^{2}M)$ attains some extreme value (the module-version of Buchsbaum rings with maximal embedding dimension).

PROPOSITION 5.11 (cf. [8, Theorem 1.1]). Suppose that M is a generalized C-M module and

$$l(M/\mathfrak{a}^{2}M) = e(\mathfrak{a}; M) + I(M) + dl(M/\mathfrak{a}M).$$

Then $G_{\mathfrak{s}}(M)$ is a generalized C-M module with

$$H^i_{\mathcal{Q}}(G_{\mathfrak{a}}(M)) \cong H^i_{\mathfrak{m}}(M)(i-1)$$

for $i = 0, \dots, d-1$, and $[H^d_Q(G_a(M))]_n = 0$ for n > 1 - d, where Q denotes the maximal graded ideal of $G_a(A)$. Moreover, the ideal a^* of $G_a(A)$ generated by the initial forms of the elements of α is $G_a(M)$ -standard.

Proof. Without restriction we may assume that the residue field k is infinite. Let a_1, \dots, a_d be a minimal reduction of a relative to aM. Then $qaM = a^2M$ by Proposition 4.8 (i). Hence we have the following exact sequence of $G_q(A)$ -modules: NGÔ VIÊT TRUNG

$$0 \longrightarrow \sum_{t=0}^{\infty} \mathfrak{q}^{t} M/\mathfrak{q}^{t} \mathfrak{a} M \longrightarrow \bigoplus_{t=0}^{\infty} \mathfrak{a}^{t} M/\mathfrak{a}^{t+1} M \longrightarrow \left(\bigoplus_{t=0}^{\infty} \mathfrak{q}^{t} \mathfrak{a} M/\mathfrak{q}^{t+1} M \right) (-1) \longrightarrow 0.$$

By Lemma 4.3, from Proposition 4.8 (ii) and (iii) we get

$$\bigoplus_{t=0}^{\infty} \mathfrak{q}^t M/\mathfrak{q}^t \mathfrak{a} M \cong (M/\mathfrak{a} M)[X_1, \cdots, X_d],$$

which is a C-M module over $G_{\mathfrak{q}}(A)$ whose dth local cohomology module concentrated in degree $\leq -d$. Thus, from the above exact sequence we can deduce that

$$H^i_P(G_{\mathfrak{a}}(M)) \cong \left(H^i_P\left(\bigoplus_{t=0}^{\infty} \mathfrak{q}^t \mathfrak{a} M/\mathfrak{q}^{t+1} M \right) \right) (-1)$$

for $i = 0, \dots, d - 1$, and

$$[H^d_P(G_{\mathfrak{a}}(M))]_n \cong \left[H^d_P\left(\bigoplus_{t=0}^{\infty} \mathfrak{q}^t \mathfrak{a} M/\mathfrak{q}^{t+1} M\right)\right]_{n+1}$$

for n > -d. On the other hand, we also have the exact sequence

$$0 \longrightarrow \bigoplus_{t=0} \mathfrak{q}^t \mathfrak{a} M/\mathfrak{q}^{t+1} M \longrightarrow \bigoplus_{t=0} \mathfrak{q}^t M/\mathfrak{q}^{t+1} M \longrightarrow \bigoplus_{t=0} \mathfrak{q}^t M/\mathfrak{q}^t \mathfrak{a} M \longrightarrow 0.$$

From this it follows that

$$H^i_P \Bigl(\bigoplus_{t=0}^{\infty} \mathfrak{q}^t \mathfrak{a} M / \mathfrak{q}^{t+1} M \Bigr) \cong H^i_P (G_{\mathfrak{q}}(M))$$

for $i = 0, \dots, d - 1$, and

$$\left[H^d_P\left(\bigoplus_{t=0}^{\infty}\mathfrak{q}^t\mathfrak{a} M/\mathfrak{q}^{t+1}M\right)\right]_n\cong \left[H^d_P(G_q(M))\right]_n$$

for n > -d. But by Proposition 4.8 (ii), a_1, \dots, a_d is a standard s.o.p. of M. Hence we can estimate the local cohomology modules of $G_q(M)$ by Theorem 5.4. Note that

$$H^i_{\scriptscriptstyle Q}(G_{\mathfrak{a}}(M)) = \varinjlim_{\iota} H^i(a_1^{*\iota}, \cdots, a_d^{*\iota}; G_{\mathfrak{a}}(M)) = H^i_{\scriptscriptstyle P}(G_{\mathfrak{a}}(M)) \,,$$

 $i = 0, \dots, d$, where a_1^*, \dots, a_a^* may be understood both as elements of $G_{\mathfrak{a}}(A)$ and $G_{\mathfrak{q}}(A)$. Then from the above relations we can easily derive the formulas for $H^i_{\mathcal{Q}}(G_{\mathfrak{a}}(M))$ as required. The fact that \mathfrak{a}^* is $G_{\mathfrak{a}}(M)$ -standard follows from Corollary 3.12.

Similar to Corollary 5.6 of Theorem 5.4, we have the following consequence:

42

COROLLARY 5.12. Let M and a be as in Proposition 5.11. Let a_1, \dots, a_d be a minimal reduction of a relative to M. Then

$$(a_1^{n_1},\,\cdots,\,a_d^{n_d})M\cap \mathfrak{a}^n M=\sum\limits_{i=1}^d a_i^{n_i}\mathfrak{a}^{n-n_i}M$$

for all positive integers n_1, \dots, n_d and $n \ge 0$.

§6. Rees modules

Let a be an ideal of A with $l(M/aM) < \infty$. Then we call the graded module

$$R_{\mathfrak{a}}(M) := \bigoplus_{n=0}^{\infty} \mathfrak{a}^n M$$

over the Rees algebra $R_{\alpha}(A)$ the Rees module of M relative to α . It is also known under the name arithmetical blowing-up [3], [4].

It is well-known that $G_a(M) = R_a(M)/aR_a(M)$ and that $aR_a(M)$ may be identified with the positively graded part of $R_a(M)$ by an isomorphism of degree -1. From these facts we can show that concerning the property of being a generalized C-M module, there is a close relationship between $G_a(M)$ and $R_a(M)$.

We shall denote by Q the maximal graded ideal of $G_{a}(A)$.

- **PROPOSITION 6.1.** The following conditions are equivalent:
- (i) M and $R_{\alpha}(M)$ are generalized C-M modules.
- (ii) $G_{\alpha}(M)$ is a generalized C-M module.

Proof. (i) \Rightarrow (ii). From the exact sequences

$$0 \longrightarrow \alpha R_{\mathfrak{a}}(M)(-1) \longrightarrow R_{\mathfrak{a}}(M) \longrightarrow M \longrightarrow 0$$
$$0 \longrightarrow \alpha R_{\mathfrak{a}}(M) \longrightarrow R_{\mathfrak{a}}(M) \longrightarrow G_{\mathfrak{a}}(M) \longrightarrow 0$$

we can easily deduce that first, $\alpha R_{\alpha}(M)$ and then $G_{\alpha}(M)$ is a generalized C-M module.

(ii) \Rightarrow (i). That *M* is a generalized C-M module follows from Corollary 5.2. To show that $R_{a}(M)$ is a generalized C-M module, we may assume, without loss of generality, that *A* is a complete local ring. Then *A* is a factor of a regular ring, hence so is $R_{a}(A)$. By Lemma 1.2 (iv) and Lemma 1.4, it suffices to show:

(1) dim $R_{a}(A)/P = d + 1$ for any minimal prime divisor P of $R_{a}(M)$.

(2) $[R_{\mathfrak{a}}(M)]_{P}$ is a C-M module for every prime ideal $p \neq Q$ of Supp $(R_{\mathfrak{a}}(M))$.

For (1) we identify $R_{a}(A)$ with the subring A[aT] of A[T] (*T* is an indeterminate) generated over *A* by all elements aT, $a \in a$. It is easy to see that

$$\operatorname{Ann} \left(R_{\mathfrak{a}}(M) \right) = \operatorname{Ann} \left(M \right) A[T] \cap A[\mathfrak{a}T],$$

where Ann denotes the annihilator. From this it follows that

$$R_{\mathfrak{a}}(A)/\operatorname{Ann}\left(R_{\mathfrak{a}}(M)\right) = R_{\mathfrak{a}}(A/\operatorname{Ann}\left(M\right)).$$

Therefore, since dim $A/\mathfrak{p} = d$ for any minimal prime ideal over Ann (M) by Lemma 1.2 (iv), dim $R_{\mathfrak{a}}(A)/P = d + 1$ for any minimal prime ideal P over Ann $(R_{\mathfrak{a}}(M))$ by [28, § 1].

For (2) we set $\mathfrak{p} = P \cap A$. If $\mathfrak{a} \not\subseteq \mathfrak{p}$, we have $[A[\mathfrak{a}T]]_{\mathfrak{p}} = A_{\mathfrak{p}}[T]$. Hence $[R_{\mathfrak{a}}(M)]_{\mathfrak{p}} = M_{\mathfrak{p}}[T]$. Since by Lemma 1.2 (iv), $M_{\mathfrak{p}}$ is a C-M module, so is $[R_{\mathfrak{a}}(M)]_{P}$ as a localization of $[R_{\mathfrak{a}}(M)]_{\mathfrak{p}}$. If $\mathfrak{a} \subseteq \mathfrak{p}$, i.e. $\mathfrak{p} = \mathfrak{m}$, there exists some element $a \in \mathfrak{a}$ such that $aT \notin P$ because $P \neq Q = (\mathfrak{m}, \mathfrak{a}T)A[\mathfrak{a}T]$. Since $\mathfrak{a} \subset aA[\mathfrak{a}T, (aT)^{-1}]$,

$$[R_{\mathfrak{a}}(M)]/\mathfrak{a}[R_{\mathfrak{a}}(M)]_{P} = [R_{\mathfrak{a}}(M)]_{P}/\mathfrak{a}[R_{\mathfrak{a}}(M)]_{P} = [G_{\mathfrak{a}}(M)]_{P},$$

which is a C-M module by Lemma 1.2 (iv). Moreover, since 0_M is unmixed up to m by Lemma 1.2 (iii), using a module-version of [28, Proposition 1.1 (iii)], we can show that *a* is a non-zerodivisor of $[R_a(M)]_P$. Hence $[R_a(M)]_P$. is a C-M module, as required. The proof of Proposition 6.1 is now complete.

Now, we want to study $R_{\mathfrak{q}}(M)$ in the case $\mathfrak{a} = \mathfrak{q}$ is a standard parameter ideal. Note that in this case, $R_{\mathfrak{q}}(M) = S_{\mathfrak{q}}(M)$, which follows from property of *d*-sequences, see [13], [14], [27], [29]. Then the following result also holds for symmetric modules:

THEOREM 6.2 (cf. [4, (11.1)]). Let a_1, \dots, a_d be a standard s.o.p. of M. Then $R_q(M)$ is a generalized C-M module with

$$egin{aligned} &H^{\mathfrak{o}}_{Q}(R_{\mathfrak{q}}(M))=H^{\mathfrak{o}}_{\mathfrak{m}}(M)\ &H^{i}_{Q}(R_{\mathfrak{q}}(M))= \bigoplus_{i-2 \geq n \geq 1}H^{i-1}_{\mathfrak{m}}(M)(n) \end{aligned}$$

for $i = 1, \dots, d$, where $H^i_m(M)$ is considered as a graded module over $R_q(M)$ concentrated in degree 0, and $[H^{d+1}_Q(R_q(M))]_n = 0$ for $n \ge 0$.

Proof. For brevity we set $M^* = R_q(M)$. Since by Corollary 2.3, $qM \cap H^0_m(M) = 0$, we have

$$H^{\scriptscriptstyle 0}_{\scriptscriptstyle Q}(M^*)= \mathop{\oplus}\limits_{n=0}^{\infty} \mathfrak{q}^n M\cap H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)=H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)(0) \ .$$

To estimate $H^i_{\mathcal{Q}}(M^*)$, $i \geq 1$, we consider the exact sequences

$$\begin{array}{ccc} 0 \longrightarrow \mathfrak{q} M^*(-1) \longrightarrow M^* \longrightarrow M \longrightarrow 0 \\ 0 \longrightarrow \mathfrak{q} M^* \longrightarrow M^* \longrightarrow G_{\mathfrak{q}}(M) \longrightarrow 0 \ . \end{array}$$

From the first sequence we get

(1)
$$[H^i_Q(\mathfrak{q}M^*)]_n \cong [H^i_Q(M^*)]_{n+1}$$

for $n \neq -1$. Using Theorem 5.4, from the second sequence we get

(2)
$$[H^i_Q(\mathfrak{q}M^*)]_n \cong [H^i_Q(M^*)]_n$$

for $n \neq -i$, 1 - i, and the exact sequences

$$(3) \qquad \qquad 0 \longrightarrow [H^i_Q(\mathfrak{q}M^*)]_{-i} \longrightarrow [H^i_Q(M^*)]_{-i}$$

$$(4) \qquad [H^{i-1}_{Q}(M^{*})]_{1-i} \longrightarrow H^{i-1}_{m}(M) \longrightarrow [H^{i}_{Q}(\mathfrak{q}M^{*})]_{1-i} \longrightarrow [H^{i}_{Q}(M^{*})]_{1-i}.$$

Since $H_{Q}^{i}(M^{*})$ is an artinian module, $[H_{Q}^{i}(M^{*})]_{n} = 0$ for n large enough. Hence, from (1) and (2) we get $[H_{Q}^{i}(M^{*})]_{n} = 0$ for $n \geq 0$. Now let $i = 1, \dots, d-1$. Note that by Theorem 5.4 and Proposition 6.1 $H_{Q}^{i}(M^{*})$ is of finite length. Then $[H_{Q}^{i}(M^{*})]_{n} = 0$ for n small enough. Hence, using (1), (2) and (3) we get $[H_{Q}^{i}(M^{*})]_{n} = 0$ for $n \leq 1-i$. Now, from (1), (2) and (4) we can conclude that

$$[H^{i}_{Q}(M^{*})]_{n} = [H^{i}_{Q}(\mathfrak{q}M^{*})]_{1-i} = H^{i-1}_{m}(M)$$

$$R_{n}(A)^{+}[H^{i}_{Q}(M^{*})]_{n} = 0$$

for $i-2 \ge n \ge 1$. Thus, $H^i_{Q}(M^*)$ is the direct sum of $H^{i-1}_{\mathfrak{m}}(M)(n)$, i-2 $n \ge 1$. The proof of Theorem 6.2 is complete.

Remark 6.3. By the statement of Theorem 6.2 we always have $H^1_Q(R_q(M)) = 0$, and, if $d \ge 2$, $H^2_Q(R_q(M)) = 0$.

The following consequence of Theorem 6.2 is the content of Schenzel's paper [19] which generalizes similar result of Goto and Shimoda in the theory of Buchsbaum rings [7], [12].

COROLLARY 6.4. Let q be an arbitrary parameter ideal of M. Then $R_{0}(M)$ is a C-M module iff the following conditions are satisfied:

(i)
$$H^i_m(M) = 0$$
 for $i \neq 1, d$.

(ii) $qH^1_m(M) = 0.$

Proof. (\Rightarrow) First, we have $H^0_{\mathfrak{m}}(M) = [H^0_{\mathcal{Q}}(R_{\mathfrak{q}}(M)]_0 = 0$. For i > 0, we consider the exact sequences

$$0 \longrightarrow \mathfrak{q}R_{\mathfrak{q}}(M)(-1) \longrightarrow R_{\mathfrak{q}}(M) \longrightarrow M \longrightarrow 0$$
$$0 \longrightarrow \mathfrak{q}R_{\mathfrak{q}}(M) \longrightarrow R_{\mathfrak{q}}(M) \longrightarrow G_{\mathfrak{q}}(M) \longrightarrow 0.$$

Since $H^i_Q(R_q(M)) = 0$, $i = 0, \dots, d$, it is easily seen that

$$H^i_{\mathcal{O}}(G_{\mathfrak{g}}(M)) \cong H^i_{\mathfrak{m}}(M)(1)$$

for $i = 1, \dots, d - 1$. Thus, by Corollary 3.12, a_1^*, \dots, a_d^* is a standard s.o.p. of $G_q(M)$. Hence, by Corollary 5.5, a_1, \dots, a_d is a standard s.o.p. of M, which then implies (ii). Moreover, we can compare the above formula for $H_Q^i(G_q(M))$ with the one of Theorem 5.4 and immediately get (i).

(\Leftarrow) By Corollary 3.7, q is a standard parameter ideal of M. Hence, by Theorem 6.2, $R_{\mathfrak{q}}(M)$ is a C-M module.

Theorem 6.2 may be also applied to study the Rees modules of the module-version of Buchsbaum rings with maximal embedding dimension.

PROPOSITION 6.5. Suppose that M is a generalized C-M module with $d \ge 2$ and

$$l(M/\mathfrak{a}^{2}M) = e(\mathfrak{a}; M) + I(M) + dl(M/\mathfrak{a}M).$$

Then $R_{\alpha}(M)$ is a generalized C-M module with

$$egin{aligned} &H^{\scriptscriptstyle 0}_{\scriptscriptstyle Q}(R_{\scriptscriptstyle \mathfrak{a}}(M))=H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)\oplus H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)(-1)\ &H^{\scriptscriptstyle 1}_{\scriptscriptstyle Q}(R_{\scriptscriptstyle \mathfrak{a}}(M))=H^{\scriptscriptstyle 1}_{\scriptscriptstyle \mathfrak{m}}(M)\ &H^{\scriptscriptstyle i}_{\scriptscriptstyle Q}(R_{\scriptscriptstyle \mathfrak{a}}(M))=\bigoplus_{i=0\geq n\geq 1}H^{1-1}_{\scriptscriptstyle \mathfrak{m}}(M)(n) \end{aligned}$$

for $2 \leq i \leq d$, and $[H_Q^{d+1}(R_{\mathfrak{a}}(M))]_n = 0$ for $n \geq 0$.

Proof. Without restriction we may assume that the residue field k is infinite. Let a_1, \dots, a_d be a minimal reduction of a relative to M (hence to aM too). Then, by Proposition 4.8 (i),

$$\mathfrak{qa}^n M = \mathfrak{a}^{n+1} M$$

for all $n \ge 1$. By Proposition 4.8 (ii) and Corollary 2.3, $\mathfrak{q}M \cap H^{\mathfrak{o}}_{\mathfrak{m}}(M) = 0$. By Corollary 2.6 (iv) and Proposition 4.8 (iii),

$$H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)=0_{\scriptscriptstyle M}\colon a_{\scriptscriptstyle d}\subseteq \mathfrak{q}_{\scriptscriptstyle d-1}M\colon a_{\scriptscriptstyle d}\subseteq \mathfrak{a}M$$
 .

46

Using these facts, it is easy to see that

$$H^{\scriptscriptstyle 0}_{\scriptscriptstyle Q}(R_{\scriptscriptstyle \mathfrak{a}}(M))=H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)\oplus H^{\scriptscriptstyle 0}_{\scriptscriptstyle \mathfrak{m}}(M)(-1)$$
 .

To estimate $H^i_{\mathbb{Q}}(R_{\mathfrak{a}}(M))$, $i \geq 1$, we first consider the exact sequence

$$0 \longrightarrow \mathfrak{a} R_{\mathfrak{a}}(M)(-1) \longrightarrow R_{\mathfrak{a}}(M) \longrightarrow M \longrightarrow 0.$$

Then we have

$$[H^i_Q(R_{\mathfrak{a}}(M))]_n = [H^i_Q(\mathfrak{a}R_{\mathfrak{a}}(M))]_{n-1}$$

for $n \neq 0$. Note that $\alpha R_{\alpha}(M) = R_{\alpha}(\alpha M) = R_{\alpha}(\alpha M)$ and that a_1, \dots, a_d is a standard s.o.p. of αM by Corollary 4.9 (ii). Then we can apply Theorem 6.2 to αM and get

$$H^{i}_{Q}(\mathfrak{a}R_{\mathfrak{a}}(M)) = \bigoplus_{i-2 \ge n \ge 1} H^{i-1}_{\mathfrak{m}}(\mathfrak{a}M)(n)$$

for $i = 1, \dots, d$, and $[H_Q^{d+1}(\mathfrak{a}R_\mathfrak{a}(M))]_n = 0$ for $n \ge 0$. Since $H_\mathfrak{m}^i(\mathfrak{a}M) = H_\mathfrak{m}^i(M)$ for i > 1, from the above relations we can easily derive the formulas for $H_Q^i(R_\mathfrak{a}(M))$ of Proposition 6.5 except the following ones:

$$egin{aligned} & [H^1_Q(R_\mathfrak{a}(M))]_\mathfrak{0} = H^1_\mathfrak{m}(M) \ & [H^i_Q(R_\mathfrak{a}(M))]_\mathfrak{0} = 0 \end{aligned}$$

for i > 1. But these formulas are easily seen from the zero-graded part of the derived local cohomology sequence of the exact sequence

$$0 \longrightarrow \mathfrak{a}R_{\mathfrak{a}}(M) \longrightarrow R_{\mathfrak{a}}(M) \longrightarrow G_{\mathfrak{a}}(M) \longrightarrow 0$$

by using the above formula of $H^i_Q(\mathfrak{a}R_\mathfrak{a}(M))$ and the one of $H^i_Q(G_\mathfrak{a}(M))$ of Proposition 5.11.

Remark 6.6. (1) By the statement of Proposition 6.5 we always have $H^{\circ}_{\mathcal{Q}}(R_{\mathfrak{a}}(M)) = 0$ and, if $d \geq 3$, $H^{\circ}_{\mathcal{Q}}(R_{\mathfrak{a}}(M)) = 0$.

(2) If d = 1, we get another formula for $H^1_Q(R_a(M))$ than the one of Proposition 6.5. Namely, using the same method as in the proof of Proposition 6.5, we can show that in this case,

$$egin{aligned} &H^0_Q(R_\mathfrak{a}(M))=H^0_\mathfrak{m}(M)\oplus H^0_\mathfrak{m}(M)(-1)\ &H^1_Q(R_\mathfrak{a}(M))=0\ &[H^2_Q(R_\mathfrak{a}(M))]_n=0 & ext{for }n\geqq 0\,. \end{aligned}$$

From Proposition 5.6 and Remark 6.6 we immediately get the following interesting consequence:

NGÔ VIÊT TRUNG

COROLLARY 6.7. Let M and a be as in Proposition 6.5 Then $R_{a}(M)$ is a C-M module iff $H^{i}_{m}(M) = 0$ for $i \neq 2, d$.
