## INFINITE OUTER GALOIS THEORY OF NON COMMUTATIVE RINGS

YASUJI TAKEUCHI

(Received August 26, 1966)

In [4], T. Nagahara presented infinite Galois theory of commutative rings with no non-trivial idempotent. On the other hand, Y. Miyashita studied in [3] finite outer Galois theory of non commutative rings.

We shall introduce the notion of infinite outer Galois extension of non commutative rings and obtain a generalization of the fundamental theorem of Galois theory.

In the first place, we recall the definition of finite Galois extension of non commutative rings. Let  $\Gamma$  be a ring with identity 1,  $\Lambda$  a subring with the same identity 1 and G a finite group of automorphisms of  $\Gamma$ . Then  $\Gamma$  is called a (finite) Galois extension of  $\Lambda$  relative to a group G if the following conditions hold:

(1) There exists an element z of  $\Gamma$  such that  $t_G(z)=1$  where  $t_G(x)=\sum_{\sigma\in\mathcal{G}}\sigma(x)$  for any element x of  $\Gamma$ .

(2)  $\Lambda = \Gamma^G$  where  $\Gamma^G$  is the fixed ring of  $\Gamma$  by G, i.e.  $\Gamma^G$  is the set of all elements of  $\Gamma$  left invariant by G.

(3) There are elements  $x_1, x_2, \dots, x_n$  and  $y_1, y_2, \dots, y_n$  of  $\Gamma$  such that for all  $\sigma$  in G

$$\sum_{i=1}^{n} x_i \sigma(y_i) = \begin{cases} 1 & (\sigma=1) \\ 0 & (\sigma=1) \end{cases}$$

If  $\Gamma$  is a finite Galois extension of  $\Lambda$  relative to group G and  $V_{\Gamma}(\Lambda)$  is the center C of  $\Gamma$  where  $V_{\Gamma}(\Lambda)$  is the commutor ring of  $\Lambda$  in  $\Gamma$ , then  $\Gamma$  is called a finite outer Galois extension of  $\Lambda$  relative to a group G [cf. 3]. This notion will be extended to the following case.

Let  $\Gamma$  be a ring with identity 1,  $\Omega$  a subring of  $\Gamma$  and  $\sigma$ ,  $\tau$  are two mappings of  $\Omega$  to  $\Gamma$ . If there exists  $\omega \in \Omega$  such that  $\sigma(\omega)e \pm \tau(\omega)e$  for any central idempotent e of  $\Gamma$ , we say that the mappings  $\sigma$  and  $\tau$  are strongly distinct. Moreover let G be a group of automorphisms of  $\Gamma$  (not necessarily finite). Then by G-strong subring we mean a subring  $\Omega$  of  $\Gamma$  to which the restrictions of any two elements of G are either equal or strongly distinct as mappings

Y. TAKEUCHI

of  $\Omega$  to  $\Gamma$ . Fixing a representative system  $\{\sigma_1, \sigma_2, \dots, \sigma_n\}$  of the right cosets of Hin G for any finite index subgroup H of G,  $t_{G/H}$  means  $t_{G/H}(x) = \sum_{i=1}^n \sigma_i(x)$  for  $x \in \Gamma$ .

DEFINITION. Let  $\Gamma$  and G be as above and  $\Lambda$  a subring of  $\Gamma$  with the same identity 1. Then it is said that  $\Gamma$  is an outer Galois extension of  $\Lambda$  relative to a group G if the following conditions (from now on, we shall call them the outer Galois conditions) are satisfied:

(1)  $t_{G/N^*}(\Gamma^N) = \Lambda$  for any finite index subgroup N of G where  $N^* = \{\sigma | \sigma \in G, \sigma(x) = x \text{ for all } x \in \Gamma^N \}$ .

(2) For any finite subset F of  $\Gamma$ , there exists a subring  $\Omega$  of  $\Gamma$  containing  $\Lambda$  such that a)  $F \subset \Omega$ , b)  $\Omega$  is a separable extension<sup>1)</sup> of  $\Lambda$ , c)  $\Omega$  is G-strong, and d) H is a finite index subgroup of G where  $H = \{\sigma | \sigma \in G, \sigma(x) = x \text{ for any } x \in \Omega\}$  and there exists an element  $\omega_K$  of  $\Omega$  such that  $t_{K/H}(\omega_K) = 1$  for any subgroup K of G containing H.

(3)  $V_{\Gamma}(\Lambda) = C$  where C is the center of  $\Gamma$ .

Throughout this paper, we assume that  $\Gamma$  is an outer Galois extension of  $\Lambda$  relative to a group G and  $\Lambda$ -module means right  $\Lambda$ -module.

First we shall present a characterization of outer Galois extensions.

From the Definition we obtain clearly next Lemma.

**Lemma 1.**  $\#\{\sigma(\gamma) | \sigma \in G\}$  is finite for any  $\gamma \in \Gamma$ .

**Corollary.** If  $\Omega$  is a subring of  $\Gamma$  finitely generated as  $\Lambda$ -module, then  $\sharp(G|\Omega)$  is finite.

**Lemma 2.** Let  $\Omega$  be a subring of  $\Gamma$  such that  $\Omega$  is a separable extension of  $\Lambda$  and is G-strong. If  $\#(G|\Omega)$  is finite, then the following statements hold: 1)  $\Omega = \Gamma^{H}$  where  $H = \{\sigma | \sigma \in G, \sigma(x) = x \text{ for all } x \in \Omega\}$ . 2)  $\Omega$  is a finitely generated projective  $\Lambda$ -module.

Proof. Let  $x_1, x_2, \dots, x_n$  and  $y_1, y_2, \dots, y_n$  be elements of  $\Omega$  satisfying the separability conditions. If we write e the image of  $\sum_{i=1}^{n} x_i \otimes y_i$  by the natural mapping of  $\Omega \bigotimes_{\Lambda} \Omega$  to  $\Omega \bigotimes_{\Lambda} \Gamma$  and set  $e_{\sigma} = (1 \otimes \sigma)(e)$  for  $\sigma \in G$ , it is clear that xe = ex and  $xe_{\sigma} = e_{\sigma}\sigma(x)$  for any  $x \in \Omega$ . Let  $\varphi$  be a mapping of  $\Omega \bigotimes_{\Lambda} \Gamma$  onto  $\Gamma$  by  $\varphi(x \otimes y) = xy$  for any  $x \otimes y \in \Omega \otimes \Gamma$ . Then  $\varphi(e_{\sigma})$  belongs to the center C of  $\Gamma$ 

196

<sup>1)</sup> Let  $\Gamma$  be a ring with identity 1,  $\Lambda$  a subring of  $\Gamma$ .  $\Gamma$  is called a separable extension of  $\Lambda$  if there exist  $x_1, x_2, \dots, x_n$  and  $y_1, y_2, \dots, y_n$  of  $\Gamma$  such that  $\sum_{i=1}^n x_i y_i = 1$  and  $\sum_{i=1}^n x_i \otimes y_i = \sum_{i=1}^n x_i \otimes y_i z_i$  for any  $z \in \Gamma$  where  $\sum_{i=1}^n x_i \otimes y_i \in \Gamma \otimes \Gamma$ . In this case, we shall say that  $x_1, x_2, \dots, x_n$  and  $y_1, y_2, \dots, y_n$  satisfy the separablity conditions.

since  $x\varphi(e_{\sigma}) = \varphi(e_{\sigma})\sigma(x)$  for any  $x \in \Omega$ . We have that  $\varphi(e_{\sigma}) = (\sum_{i=1}^{n} x_i y_i)\varphi(e_{\sigma}) = (\sum_{i=1}^{n} x_i \sigma(y_i))\varphi(e_{\sigma}) = \varphi(e_{\sigma})^2$ . Therefore for all  $\sigma \in G$ 

$$\sum_{i=1}^{n} x_i \sigma(y_i) = \begin{cases} 1 & (\sigma \in H) \\ 0 & (\sigma \in H) \end{cases}$$

since  $\Omega$  is G-strong. Since the index of H in G is finite, we have  $\omega = \sum_{i=1}^{n} x_i t_{G/H}$  $(y_i \omega)$  for any  $\omega \in \Omega$ . Thus  $\Omega$  is a finitely generated projective  $\Lambda$ -module. The remaining part is trivial from the fact that  $\gamma = \sum_{i=1}^{n} x_i t_{G/H}(y_i \gamma)$  for any  $\gamma \in \Gamma^H$ .

**Lemma 3.** Let F be any finite subset of  $\Gamma$ . Then there exists a normal subgroup N of G such that the index of N in G is finite,  $F \subset \Gamma^N$  and  $\Gamma^N$  is a (finite) outer Galois extension of  $\Lambda$  relative to G/N.

Proof. If  $F^* = \{\sigma(x) | \sigma \in G, x \in F\}$ ,  $F^*$  is finite. Let  $\Omega$  be a subring of  $\Gamma$  satisfying the outer Galois conditions (2) for a finite subset  $F^*$  of  $\Gamma$ . Then  $\Omega = \Gamma^H$  where  $H = \{\sigma | \sigma \in G, \sigma(x) = x \text{ for all } x \in \Omega\}$ . If N is the normal subgroup of G generated by H, we have  $F \subset \Gamma^N$ . Let  $x_1, x_2, \dots, x_n$  and  $y_1, y_2, \dots, y_n$  be elements of  $\Omega$  satisfying the separability conditions. Then we have already known

$$\sum_{i=1}^{n} x_i \sigma(y_i) = \begin{cases} 1 & (\sigma \in H) \\ 0 & (\sigma \notin H) \end{cases}$$

for all  $\sigma \in G$ . Since there exists  $\omega_N \in \Omega$  such that  $t_{N/H}(\omega_N) = 1$ , we obtain

$$\sum_{i=1}^{n} t_{N/H}(\omega_N x_i) \sigma(t_{N/H}(y_i)) = \begin{cases} 1 & (\sigma \in N) \\ 0 & (\sigma \in N) \end{cases}$$

for all  $\sigma \in G$ . Hence  $N = \{\sigma \mid \sigma \in G, \sigma(x) = x \text{ for all } x \in \Gamma^N\}$ , so that there exists  $\gamma_N \in \Gamma^N$  such that  $t_{G/N}(\gamma_N) = 1$ . Since  $V_{\Gamma^N}(\Lambda)$  is clearly the center of  $\Gamma^N$ ,  $\Gamma^N$  is a (finite) outer Galois extension of  $\Lambda$  relative to G/N.

**Lemma 4.** (cf. [3]). Let  $\Gamma$  be a finite outer Galois extension of  $\Lambda$  relative to G. Then if H is any subgroup of G,  $\Gamma^{H}$  is a separable extension of  $\Lambda$  finitely generated as  $\Lambda$ -module and G-strong. Moreover if H is a normal subgroup of G,  $\Gamma^{H}$ is a (finite) outer Galois extension of  $\Lambda$  relative to G/H.

**Proposition 2.** If H is a subgroup of G such that the index of H in G is finite, then we obtain that  $\Gamma^{H}$  is a separable extension of  $\Lambda$  finitely generated as  $\Lambda$ -module and G-strong.

Proof. Let  $\gamma_1$  be one of generators of  $\Gamma^H$  as  $\Lambda$ -module. Then there exists a normal subgroup  $N_1$  of G such that  $\gamma_1 \in \Gamma^{N_1}$  and  $\Gamma^{N_1}$  is a Galois exten-

Y. TAKEUCHI

sion of  $\Lambda$  relative to  $G/N_1$ . Assume that  $N_{k-1}$  exists. If we can take out  $\gamma_k$  being one of generators of  $\Gamma^H$  as  $\Lambda$ -module not included in  $\Gamma^{N_{k-1}}$ ,  $N_k$  is a normal subgroup of G such that  $\gamma_k \in \Gamma^{N_k}$ ,  $\Gamma^{N_{k-1}} \subset \Gamma^{N_k}$  and  $\Gamma^{N_k}$  is a finite Galois extension of  $\Lambda$  relative to  $G/N_k$ . Then we have a chain

$$G \supset HN_1 \supset HN_2 \supset \cdots \supset HN_k \supseteq H.$$

Hence

$$[G:H] > [HN_1:H] > [HN_2:H] > \dots > [HN_k:H] \ge 1$$

Since [G:H] is finite, there is a rational integer  $k_0$  such that  $\Gamma^H \subset \Gamma^N k_0$ .  $\Gamma^H$  is the fixed ring of  $\Gamma^N k_0$  by  $HN_{k_0}/N_{k_0}$ , so that  $\Gamma^H$  is a separable extension of  $\Lambda$  finitely generated as  $\Lambda$ -module and G-strong.

**Corollary.** If N is a normal subgroup of finite index in G,  $\Gamma^N$  is a (finite) outer Galois extension of  $\Lambda$  relative to a factor group of G.

Proof. (cf. [3]).

Now we summarize a characterization of outer Galois extensions.

**Proposition 3.** Let  $\tilde{\Gamma}$  be a ring with identity 1,  $\tilde{\Lambda}$  a subring of  $\tilde{\Gamma}$  with same identity 1 and G a group of automorphisms of  $\tilde{\Gamma}$ .

Then  $\tilde{\Gamma}$  is an outer Galois extension of  $\tilde{\Lambda}$  relative to G if and only if the following conditions hold:

(1)  $\tilde{\Gamma}^{G} = \tilde{\Lambda}$ .

(2) For any finite subset F of  $\tilde{\Gamma}$ , there exists a normal subgroup  $\tilde{N}$  of  $\tilde{G}$  such that  $F \subset \tilde{\Gamma}^N$ , the index of  $\tilde{N}$  in  $\tilde{G}$  is finite and  $\tilde{\Gamma}^N$  is a finite outer Galois extension of  $\tilde{\Lambda}$  relative to  $\tilde{G}/\tilde{N}$ .

Proof. Necessity. It is obvious from Lemma 3 and 4.

Sufficiency. It follows from the proof of Proposition 2 that  $\Gamma^H$  is finitely generated as  $\Lambda$ -module for any finite index subgroup H of G. Then there exists a normal subgroup N of G such that  $\Gamma^H \subset \Gamma^N$  and  $\Gamma^N$  is a finite Galois extension of  $\Lambda$  relative to G/N. Hence we have  $t_{G/\overline{H}}(\Gamma^H) = \Lambda$  where  $\overline{H} = {\sigma \mid \sigma \in G, \sigma(x) = x \text{ for all } x \in \Gamma^H}$ . The remainder of the proof is obvious.

**Lemma 5.** Let  $\Omega$  be a subring of  $\Gamma$  which is a separable extension of  $\Lambda$  finitely generated as  $\Lambda$ -module and G-strong. If M is a left free  $\Gamma$ -module  $\sum_{i=1}^{n} \oplus \Gamma \sigma'_{i}$  where  $G \mid \Omega = \{\sigma'_{1}, \sigma'_{2}, \dots, \sigma'_{m}\}$ , we may regard M as a right  $\Omega$ -module by  $x \cdot \sigma'_{i} \cdot y = x\sigma'_{i}(y)\sigma'_{i}$  for  $x \in \Gamma$ ,  $y \in \Omega$ .

Then if  $\psi$  is a mapping of M to Hom  $(\Omega_{\Lambda}, \Gamma_{\Lambda})$  by  $\psi(\sum_{i=1}^{m} \gamma_{i} \cdot \sigma'_{i})(y) = \sum_{i=1}^{m} \gamma_{i} \cdot \sigma'_{i}(y)$ for  $\sum_{i=1}^{m} \gamma_{i} \sigma'_{i} \in M$ ,  $y \in \Omega$ ,  $\psi$  is  $\Gamma$ - $\Omega$ -isomorphism.

198

Proof. (cf. [4]).

REMARK. In the above Lemma, if  $\Lambda = \Gamma^G$  and  $\#\{\sigma(\gamma) | \sigma \in G\}$  is finite for any  $\gamma \in \Gamma$ , we may omit the assumption that  $\Gamma$  is an outer Galois extension of  $\Lambda$  relative to G.

**Proposition 4.** Let  $G^*$  be the closure of G (with respect to the finite topology). Then  $\Gamma$  is an outer Galois extension of  $\Lambda$  relative to  $G^*$ .

Proof. For any finite subset F of  $\Gamma$ , there exists a normal subgroup N of G such that  $\Gamma^N$  is a finite outer Galois extension of  $\Lambda$  relative to G/N. Then we have  $G|\Gamma^N = G^*|\Gamma^N$ . Hence  $\Gamma^{N^*}$  is a finite Galois extension of  $\Lambda$  relative to  $G^*/N^*$  where  $N^* = \{\sigma \mid \sigma \in G^*, \sigma(x) = x \text{ for all } x \in \Gamma^N\}$ .

DEFINITION. Let  $\Omega$  be a subring of  $\Gamma$  containing  $\Lambda$ . Then we shall call  $\Omega$  is a locally separable G-strong extension of  $\Lambda$  if, for any finite subset F of  $\Omega$ , there exists a subring  $\Omega'$  of  $\Omega$  containing F which is a separable extension of  $\Lambda$  finitely generated as  $\Lambda$ -module and G-strong.

**Proposition 5.** If H is a closed subgroup of G (with respect to the finite topology), then  $\Gamma^H$  is a locally separable G-strong extension of  $\Lambda$  and  $H=H^*$  where  $H^* = \{\sigma | \sigma \in G, \sigma(x) = x \text{ for all } x \in \Gamma^H \}$ .

Proof. Let F be a finite subset of  $\Gamma^{H}$ . Then there exists a normal subgroup N of G such that the index of N in G is finite,  $F \subset \Gamma^{N}$  and  $\Gamma^{N}$  is an outer Galois extension of  $\Lambda$  relative to G/N. Since  $\Gamma^{H} \cap \Gamma^{N} = \Gamma^{HN} = (\Gamma^{N})^{HN/N}$ ,  $\Gamma^{H} \cap \Gamma^{N}$  is a separable extension of  $\Lambda$  finitely generated as  $\Lambda$ -module and G-strong. Hence  $\Gamma^{H}$  is a locally separable G-strong extension of  $\Lambda$ . We shall show the remaining part. Let F be any finite subset of  $\Gamma$ . Then there exists a subring  $\Omega$  of  $\Gamma$  which is a finite outer Galois extension of  $\Lambda$  relative to a factor group of G and contain F. Then  $H \mid \Omega = H^* \mid \Omega$  by finite Galois theory (cf. [2]), so that  $H \mid F = H^* \mid F$ . Thus we have  $H = H^*$  since H is dense in  $H^*$ .

**Corollary 1.** Let  $H_1$ ,  $H_2$  be two closed subgroup of G. If  $\Gamma^{H_1} \supset \Gamma^{H_2}$ , we have  $H_1 \subset H_2$ .

**Corollary 2.** Let  $H_1$ ,  $H_2$  be as above. If  $H_1 \neq H_2$ , then  $\Gamma^{H_1} \neq \Gamma^{H_2}$ . Now we may exhibit the fundamental theorem of outer Galois theory.

**Theorem.** 1) Let  $\Gamma$  be an outer Galois extension of  $\Lambda$  relative to a group G and assume that G is compact (with respect to the finite topology). Then there is one-to-one lattice-inverting correspondence between closed subgroups of G and subrings of  $\Gamma$  which are locally separable G-strong extension of  $\Lambda$ . If  $\Omega$  is a locally separable G-strong extension of  $\Lambda$ , which is a subring of  $\Gamma$ , then the corresponding subgroup is  $H_{\Omega} = \{\sigma \mid \sigma \in G, \sigma(x) = x \text{ for all } x \in \Omega\}$ .

## Y. TAKEUCHI

2) A closed subgroup N of G is normal in G if and only if  $\Gamma^N$  is mapped onto itself by every elements of G, in which case  $\Gamma^N$  is an outer Galois extension of  $\Lambda$ relative to G/N.

Proof. 2) is obvious. We need only show that if  $\Omega$  is a subring of  $\Gamma$ which is a locally separable G-strong extension of  $\Lambda$ , then  $\Omega = \Gamma^H$  where  $H = \{\sigma \mid \sigma \in G, \sigma(x) = x \text{ for all } x \in \Omega\}$ . Suppose that there exists  $\gamma \in \Gamma^H$  such that  $\gamma \notin \Omega$ . If  $C = \{\sigma \mid \sigma \in G, \sigma(\gamma) \neq \gamma\}$ , C is closed in G. Let X be the set of subring  $\Omega_{\alpha}$  of  $\Omega$  which is separable extension of  $\Lambda$  finitely generated as  $\Lambda$ module and G-strong (Let I be the set of suffixes of  $\Omega_{\alpha}$ 's). If  $H_{\alpha} = \{\sigma \mid \sigma \in G, \sigma(x) = x \text{ for all } x \in \Omega_{\alpha}\}$  for each  $\Omega_{\alpha} \in X$ ,  $H_{\alpha}$  is closed subgroup of G. Let  $\{\Omega_{1}, \Omega_{2}, \dots, \Omega_{n}\}$  be any finite subset of X. Then there exists a subring  $\Omega'$  of  $\Omega$ such that  $\Omega_{i} \subset \Omega'$  ( $i=1, 2, \dots, n$ ), and  $\Omega'$  is a separable extension of  $\Lambda$  finitely generated as  $\Lambda$ -module and G-strong. If  $K = \{\sigma \mid \sigma \in G, \sigma(x) = x \text{ for all } x \in \Omega'\}$ ,  $\Omega' = \Gamma^{K}$  and so  $K \subseteq \bigcap_{i=1}^{n} H$ . Since  $C \cap K \neq \phi$ ,  $\bigcap_{i=1}^{n} (C \cap H_i) = C \cap (\bigcap_{i=1}^{n} H_i) \neq \phi$ . Furthermore we obtain  $\bigcap_{\alpha \in I} (C \cap H_{\alpha}) \neq \phi$  since G is compact. Hence  $C \cap H \neq \phi$ . This is contradiction. Therefore  $\Omega = \Gamma^{H}$ , completing the proof.
