

## NOTE ON THE LEFSCHETZ FIXED POINT THEOREM

Dedicated to Professor A. Komatu on his 60th birthday

MINORU NAKAOKA

(Received November 28, 1968)

### 1. Introduction

Let  $V$  be an open set of the  $n$ -dimensional euclidean space  $\mathbf{R}^n$ , and  $f: V \rightarrow \mathbf{R}^n$  be a continuous map such that the fixed point set  $F = \{x \in V \mid f(x) = x\}$  is compact. If  $i: V \subset \mathbf{R}^n$ , then  $i-f$  maps  $(V, V-F)$  to  $(\mathbf{R}^n, \mathbf{R}^n-0)$ . Considering the homomorphism of the integral homology groups induced by  $i-f$ , A. Dold [2] defines the *fixed point index*  $I_f \in \mathbf{Z}$  by

$$(i-f)_* \mu_F^V = I_f \mu_0,$$

where  $\mu_0 \in H_n(\mathbf{R}^n, \mathbf{R}^n-0; \mathbf{Z})$  is an orientation of  $\mathbf{R}^n$  and  $\mu_F^V \in H_n(V, V-F; \mathbf{Z})$  is the 'fundamental' class corresponding to the orientation  $\mu_0$ . With this definition, he proves the following Lefschetz fixed point theorem:

**Theorem A.** *Let  $V$  be an open set of  $\mathbf{R}^n$ , and  $f: V \rightarrow V$  be a continuous map such that  $f(V)$  is contained in a compact set  $K \subset V$ . Then the fixed point index  $I_f$  of  $f$  and the Lefschetz number of  $(f|K)_*: H_*(K; \mathbf{Q}) \rightarrow H_*(K; \mathbf{Q})$  are both defined and they agree, where  $\mathbf{Q}$  is the field of rational numbers.*

Precisely, he proves the theorem in which  $V$  is replaced by a euclidean neighborhood retract  $Y$ . However this generalization follows directly from the above one, because he defines the fixed point index of  $f: Y \rightarrow Y$  to be that of the composite  $i \circ f \circ r: V \rightarrow V$ , where  $i: Y \rightarrow V$ ,  $r: V \rightarrow Y$  ( $r \circ i = id$ ) is a euclidean neighborhood retraction.

On the other hand, R. Brown [1] shows the Lefschetz fixed point theorem for a compact orientable  $n$ -dimensional topological manifold  $M$  (see also [3]). Taking an orientation of  $M$ , let  $\mu \in H_n(M; \mathbf{Z})$  and  $U \in H^n(M \times M, M \times M - d(M); \mathbf{Z})$  denote the corresponding fundamental class and Thom class respectively, where  $d(M)$  is the diagonal of  $M \times M$ . Denote by  $U' \in H^n(M \times M; \mathbf{Z})$  the image of  $U$  under the natural homomorphism. Then the theorem of Brown is as follows:

**Theorem B.** *Let  $M$  be a compact orientable  $n$ -dimensional topological*

manifold, and  $f : M \rightarrow M$  be a continuous map. Define  $\hat{f} : M \rightarrow M \times M$  by  $\hat{f}(x) = (f(x), x)$  for  $x \in M$ . Then the Kronecker product  $\langle \hat{f}^* U', \mu \rangle$  is equal to the Lefschetz number of  $f_* : H_*(M; \mathbf{Q}) \rightarrow H_*(M; \mathbf{Q})$ .

The purpose of this note is to prove a theorem which contains Theorem A and B as corollaries.

Let  $M$  be an orientable  $n$ -dimensional topological manifold which is not necessarily compact, and  $f : M \rightarrow M$  be a continuous map such that the fixed point set  $F$  of  $f$  is compact. Take an orientation of  $M$ . Then the Thom class  $U \in H^n(M \times M, M \times M - d(M); \mathbf{Z})$  and the fundamental class  $\mu_F \in H_n(M, M - F; \mathbf{Z})$  are well-defined. Considering  $\hat{f} : (M, M - F) \rightarrow (M \times M, M \times M - d(M))$ , we define the fixed point index  $I(f)$  by

$$I(f) = \langle U, \hat{f}_* \mu_F \rangle \in \mathbf{Z}.$$

Then our theorem is stated as follows:

**Theorem C.** *Let  $M$  be an orientable  $n$ -dimensional topological manifold, and  $f : M \rightarrow M$  be a continuous map such that  $f(M)$  is contained in a compact set  $K \subset M$ . Then the fixed point index  $I(f)$  of  $f$  and the Lefschetz number of  $(f|_K)_* : H_*(K; \mathbf{Q}) \rightarrow H_*(K; \mathbf{Q})$  are both defined and they agree.*

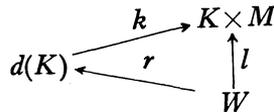

Our proof of this theorem is different from that of Theorem A due to Dold. Therefore this paper gives another proof of Theorem A.

The method we use to prove Theorem C is essentially the one due to J. Milnor [4] and is the one employed by Brown to prove Theorem B.

**2. A fundamental lemma**

Let  $M$  be an  $n$ -dimensional topological manifold, and  $d : M \rightarrow M \times M$  be the diagonal map. Let  $K$  be a compact subset of  $M$ .

**Lemma 1.** *There are an open neighborhood  $W$  of  $d(K)$  in  $K \times M$  and a retraction  $r : W \rightarrow d(K)$  such that the diagram*

*is homotopy commutative, where  $k$  and  $l$  are the inclusion maps.*

Proof. For  $r > 0$ , let

$$O_r = \{(x_1, \dots, x_n) \in \mathbf{R}^n \mid x_1^2 + \dots + x_n^2 < r\}.$$

It is easily seen that there exists a finite set  $\{V_1, \dots, V_s\}$  of coordinate neighbor-

hoods of  $M$  such that

$$\bigcup_{i=1}^s h_i^{-1}(O_1) \supset K,$$

where  $h_i : V_i \approx \mathbf{R}^n$  is a homeomorphism.

Put

$$\begin{aligned} V'_i &= h_i^{-1}(O_1), & V''_i &= h_i^{-1}(O_2), \\ V' &= \bigcup_{i=1}^s V'_i, & V'' &= \bigcup_{i=1}^s V''_i. \end{aligned}$$

The space  $\bar{V}''/\bar{V}'' - V''_i$  obtained from the closure  $\bar{V}''$  by identifying  $\bar{V}'' - V''_i$  to one point is homeomorphic with the  $n$ -sphere  $S^n$ . Therefore a homeomorphism  $f$  of  $V''$  into  $S^n \times \cdots \times S^n$  ( $s$  times) is defined by

$$f(x) = (f_1 p_1(x), \dots, f_s p_s(x)) \quad (x \in V''),$$

where  $p_i : \bar{V}'' \rightarrow \bar{V}''/\bar{V}'' - V''_i$  is the projection and  $f_i : \bar{V}''/\bar{V}'' - V''_i \approx S^n$  is a homeomorphism. Since  $\bar{V}' \subset \bar{V}''$  and  $S^n \times \cdots \times S^n \subset \mathbf{R}^m$  ( $m = (n+1)s$ ), we can regard  $\bar{V}'$  as a closed subset of  $\mathbf{R}^m$ . Since each  $V_i$  is an ANR, so is  $V = \bigcup_{i=1}^s V_i$ .

Consequently, the inclusion map  $\bar{V}' \subset V$  has an extension  $g : Q \rightarrow V$ , where  $Q$  is a neighborhood of  $\bar{V}'$  in  $\mathbf{R}^m$ . It is obvious that there exists  $\varepsilon > 0$  such that if  $x, y \in \bar{V}'$  and the distance from  $x$  to  $y$  in  $\mathbf{R}^m$  is smaller than  $\varepsilon$  then  $(1-t)x + ty \in Q$  for any  $t \in [0, 1]$ . Put

$$W = \{(x, y) \in K \times V' \mid d(x, y) < \varepsilon\},$$

and define  $r : W \rightarrow d(K)$  by  $r(x, y) = (x, x)$ .

We can now define a homotopy  $f_t : W \rightarrow K \times M$  of  $k \circ r$  to  $l$  by

$$f_t(x, y) = (x, g((1-t)x + ty)). \quad \text{q.e.d.}$$

Let  $R$  be a fixed principal ideal domain, and we shall take coefficients of homology and cohomology from  $R$ . Consider the cup product

$$\begin{aligned} \smile : H^*(K \times (M, M-K)) \otimes H^*(K \times M) \\ \rightarrow H^*(K \times (M, M-K)). \end{aligned}$$

**Lemma 2.** For  $\alpha \in H^*(M)$  and  $\gamma \in H^*(K \times M, K \times M - d(K))$  we have

$$j^* \gamma \smile p_1^* i^* \alpha = j^* \gamma \smile p_2^* \alpha,$$

where  $p_1 : K \times M \rightarrow K$ ,  $p_2 : K \times M \rightarrow M$  are the projections and  $i : K \rightarrow M$ ,  $j : K \times (M, M-K) \rightarrow (K \times M, K \times M - d(K))$  are the inclusion maps.

Proof. By Lemma 1 and the naturality of the cup product, we have a commutative diagram

$$\begin{array}{ccccc}
 & & H^*(K \times M) & \xrightarrow{\gamma \smile} & H^*(K \times M, K \times M - d(K)) \\
 & k^* \swarrow & \downarrow l^* & & \downarrow l^* \\
 H^*(d(K)) & \xleftarrow{r^*} & H^*(W) & \xrightarrow{l^* \gamma \smile} & H^*(W, W - d(K))
 \end{array}$$

If we define  $p : d(K) \rightarrow K$  by  $p(x, x) = x$  ( $x \in K$ ), then it holds that  $p_1 \circ k = p$  and  $p_2 \circ k = i \circ p$ . Therefore it follows that

$$\begin{aligned}
 l^*(\gamma \smile p_1^* i^* \alpha) &= l^* \gamma \smile r^* k^* p_1^* i^* \alpha \\
 &= l^* \gamma \smile r^* p^* i^* \alpha = l^* \gamma \smile r^* k^* p_2^* \alpha \\
 &= l^*(\gamma \smile p_2^* \alpha).
 \end{aligned}$$

Since  $l^* : H^*(K \times M, K \times M - d(K)) \cong H^*(W, W - d(K))$  is an excision isomorphism, we obtain

$$\gamma \smile p_2^* i^* \alpha = \gamma \smile p_2^* \alpha.$$

This, together with the naturality of the cup product, implies the desired result. q.e.d.

For topological pairs  $(X, A)$  and  $(Y, B)$ , consider the slant product

$$/ : H^*((X, A) \times (Y, B)) \otimes H_*(Y, B) \rightarrow H^*(X, A).$$

The following relations hold between the cup, cap and slant products: For  $\gamma \in H^*((X, A) \times (Y, B))$ ,  $\alpha \in H^*(X)$ ,  $\beta \in H^*(Y)$  and  $b \in H_*(Y, B)$ , we have

$$\begin{aligned}
 (1) \quad \alpha \smile (\gamma/b) &= (p_1^* \alpha \smile \gamma)/b, \\
 \gamma/(\beta \frown b) &= (\gamma \smile p_2^* \beta)/b
 \end{aligned}$$

in  $H^*(X, A)$ , where  $p_1 : X \times Y \rightarrow X$  and  $p_2 : X \times Y \rightarrow Y$  are the projections (see [5]).

By an *orientation*  $\mu$  over  $R$  of an  $n$ -dimensional topological manifold  $M$  we mean a function which assigns to each  $x \in M$  a generator  $\mu_x$  of  $H_n(M, M - x)$  which “varies continuously” with  $x$ , in the following sense. For each  $x$  there exist a neighborhood  $N$  and an element  $\mu_N \in H_n(M, M - N)$  such that the image of  $\mu_N$  in  $H_n(M, M - y)$  under the natural homomorphism is  $\mu_y$  for each  $y \in N$ .

If an orientation over  $R$  of the manifold  $M$  exists,  $M$  is called *orientable* over  $R$ .

Assume that  $M$  is orientable over  $R$  and an orientation  $\mu$  of  $M$  is given. Then it is known that, for each compact subset  $K$  of  $M$ , there is a unique element  $\mu_K \in H_n(M, M - K)$  whose image in  $H_n(M, M - x)$  under the natural homomorphism is  $\mu_x$  for any  $x \in K$  (see [3]). It is also known that there exists a unique

element  $U \in H^n(M \times M, M \times M - d(M))$  such that

$$\langle l_x^* U, \mu_x \rangle = 1$$

for any  $x \in M$ , where  $l_x : (M, M - x) \rightarrow (M \times M, M \times M - d(M))$  is a continuous map sending  $x' \in M$  to  $(x, x') \in M \times M$  (see [3], [5]). Denote by  $U_K \in H^n(K \times (M, M - K))$  the image of  $U$  under the natural homomorphism.

A simple calculation shows

$$(2) \quad U_K / \mu_K = 1.$$

We shall now prove the following fundamental lemma.

**Lemma 3.** *The diagram*

$$\begin{array}{ccc} H^q(M) & \xrightarrow{(-1)^{nq} i^*} & H^q(K) \\ \searrow \mu_K & & \nearrow U_K / \\ & H_{n-q}(M, M - K) & \end{array}$$

is commutative, where  $i : K \subset M$ .

Proof. For  $\alpha \in H^q(M)$ , we obtain by (1), (2) and Lemma 2

$$\begin{aligned} U_K / (\alpha \smile \mu_K) &= (U_K \smile p_2^* \alpha) / \mu_K \\ &= (U_K \smile p_1^* i^* \alpha) / \mu_K = (-1)^{nq} (p_1^* i^* \alpha \smile U_K) / \mu_K \\ &= (-1)^{nq} i^* \alpha \smile (U_K / \mu_K) = (-1)^{nq} i^* \alpha, \end{aligned}$$

which proves the desired result. q.e.d.

### 3. Lefschetz fixed point theorem

Let  $M$  be an  $n$ -dimensional topological manifold which is orientable over  $R$ . Let  $V$  be an open set of  $M$ , and  $K$  be a compact subset of  $V$ . Given an orientation  $\mu$  of  $M$ , we shall denote by  $\mu_K^V \in H_n(V, V - K)$  the element corresponding to  $\mu_K$  under the excision isomorphism  $H_n(V, V - K) \cong H_n(M, M - K)$ .

If  $f : V \rightarrow M$  is a continuous map such that the fixed point set  $F$  is compact, then we call

$$I(\hat{f}) = \langle U, \hat{f}_* \mu_F^V \rangle \in R$$

the *fixed point index* of  $f$ , where  $\hat{f} : (V, V - F) \rightarrow (M \times M, M \times M - d(M))$  is a continuous map given by  $\hat{f}(x) = (f(x), x)$  ( $x \in V$ ). It follows that  $I(f)$  is independent of the choice of orientation.

For a compact set  $K$  such that  $F \subset K \subset M$ , we have

$$(3) \quad I(f) = \langle U, \hat{f}_* \mu_K^V \rangle,$$

where  $\hat{f}_* : H_n(V, V-K) \rightarrow H_n(M \times M, M \times M - d(M))$ . This follows from that  $\mu_F^V$  is the image of  $\mu_K^V$  under the natural homomorphism.

**Lemma 4.** *In the case  $M = \mathbf{R}^n$ , we have*

$$(i-f)_* \mu_F^V = I(f) \mu_0,$$

where  $i-f : (V, V-F) \rightarrow (\mathbf{R}^n, \mathbf{R}^n-0)$  is a continuous map sending  $x \in V$  to  $x-f(x) \in \mathbf{R}^n$ .

*Proof.* Define  $\Delta : (\mathbf{R}^n \times \mathbf{R}^n, \mathbf{R}^n \times \mathbf{R}^n - d(\mathbf{R}^n)) \rightarrow (\mathbf{R}^n, \mathbf{R}^n-0)$  by  $\Delta(x, y) = y-x$  ( $x, y \in \mathbf{R}^n$ ). Then, for  $l_0 : (\mathbf{R}^n, \mathbf{R}^n-0) \rightarrow (\mathbf{R}^n \times \mathbf{R}^n, \mathbf{R}^n \times \mathbf{R}^n - d(\mathbf{R}^n))$ , we have  $\Delta \circ l_0 = id$ . Denote by  $\bar{\mu}_0 \in H^n(\mathbf{R}^n, \mathbf{R}^n-0)$  the dual to  $\mu_0 \in H_n(\mathbf{R}^n, \mathbf{R}^n-0)$ . Since  $\langle l_0^* \Delta^* \bar{\mu}_0, \mu_0 \rangle = 1$ , we have

$$\Delta^* \bar{\mu}_0 = U \in H^n(\mathbf{R}^n \times \mathbf{R}^n, \mathbf{R}^n \times \mathbf{R}^n - d(\mathbf{R}^n)).$$

Since  $\Delta \circ \hat{f} = i-f$ , we obtain

$$I(f) = \langle \Delta^* \bar{\mu}_0, \hat{f}_* \mu_F^V \rangle = \langle \bar{\mu}_0, (i-f)_* \mu_F^V \rangle,$$

which shows the desired result. q.e.d.

Let  $N$  be a graded module over a field  $R$ , and  $\varphi : N \rightarrow N$  be an endomorphism of degree 0 which factors through a finitely generated graded module. Taking a homogeneous basis  $\{a_\lambda\}$  of  $N$ , put

$$\varphi(a_\lambda) = \sum_{\mu} r_{\lambda\mu} a_\mu \quad (r_{\lambda\mu} \in R).$$

Then it follows that  $r_{\lambda\lambda}$  is zero except a finite number of  $\lambda$ , and that

$$\Lambda(\varphi) = \sum_{\lambda} (-1)^{\deg a_\lambda} r_{\lambda\lambda} \in R$$

is independent of the choice of  $\{a_\lambda\}$  (see [2]).  $\Lambda(\varphi)$  is called the *Lefschetz number* of  $\varphi$ .

**Theorem D.** *Let  $M$  be an  $n$ -dimensional topological manifold which is orientable over a field  $R$ , and let  $f : M \rightarrow M$  be a continuous map such that  $f(M)$  is contained in a compact set  $K \subset M$ . Then the fixed point index  $I(f)$  of  $f$  and the Lefschetz number  $\Lambda((f|K)_*)$  of the homomorphism  $(f|K)_* : H_*(K) \rightarrow H_*(K)$  of homology with coefficients in  $R$  are both defined and they agree.*

*Proof.* The fixed point set  $F$  of  $f$  is a closed subset of  $K$ , and hence is compact. Therefore  $I(f)$  is defined.

From Lemma 3 it follows that the diagram

$$\begin{array}{ccc}
H^q(K) & \xrightarrow{(-1)^{nq}(f|K)^*} & H^q(K) \\
\downarrow f^* & & \uparrow U_K/ \\
H^q(M) & \xrightarrow{\frown \mu_K} & H_{n-q}(M, M-K)
\end{array}$$

is commutative. It is obvious from the definition of the cap product that the image of the homomorphism  $\frown \mu_K$  is finitely generated. Therefore  $(f|K)^*$  factors through a finitely generated module, and hence  $\Delta((f|K)^*)$  is defined.

Let  $\{\alpha_\lambda\}$ ,  $\{\beta_\mu\}$  and  $\{\rho_\nu\}$  be homogeneous bases of  $H^*(M)$ ,  $H^*(M, M-K)$  and  $H^*(K)$  respectively, and put

$$\begin{aligned}
f^*(\rho_\nu) &= \sum_\lambda m_{\nu\lambda} \alpha_\lambda, \\
U_K &= \sum_{\nu, \mu} c_{\nu\mu} \rho_\nu \times \beta_\mu, \\
\langle \beta_\mu \smile \alpha_\lambda, \mu_K \rangle &= y_{\mu\lambda}.
\end{aligned}$$

Then it follows from the above commutative diagram that

$$\begin{aligned}
&(-1)^{n \deg \rho_\nu} (f|K)^* \rho_\nu = U_K / (f^* \rho_\nu \frown \mu_K) \\
&= \sum_{\kappa, \mu} (c_{\kappa\mu} \rho_\kappa \times \beta_\mu) / (f^* \rho_\nu \frown \mu_K) \\
&= \sum_{\kappa, \mu} c_{\kappa\mu} \langle \beta_\mu, f^* \rho_\nu \frown \mu_K \rangle \rho_\kappa \\
&= \sum_{\kappa, \lambda, \mu} c_{\kappa\mu} m_{\nu\lambda} \langle \beta_\mu, \alpha_\lambda \frown \mu_K \rangle \rho_\kappa \\
&= \sum_{\kappa, \lambda, \mu} c_{\kappa\mu} m_{\nu\lambda} \langle \beta_\mu \smile \alpha_\lambda, \mu_K \rangle \rho_\kappa \\
&= \sum_{\kappa, \lambda, \mu} c_{\kappa\mu} m_{\nu\lambda} y_{\mu\lambda} \rho_\kappa.
\end{aligned}$$

Therefore we have

$$\Delta((f|K)^*) = \sum_{\lambda, \mu, \nu} (-1)^{(n+1) \deg \rho_\nu} c_{\nu\mu} m_{\nu\lambda} y_{\mu\lambda}.$$

The diagram

$$\begin{array}{ccc}
H^*(M \times M, M \times M - d(M)) & \xrightarrow{\hat{f}^*} & H^*(M, M-K) \\
\downarrow i^* & & \uparrow d^* \\
H^*(K \times (M, M-K)) & \xrightarrow{(f \times id)^*} & H^*(M \times (M, M-K))
\end{array}$$

is commutative, where  $i^*$  is the natural homomorphism. Therefore it follows from (3) that

$$\begin{aligned}
I(f) &= \langle U, \hat{f}_* \mu_K \rangle = \langle \hat{f}^* U, \mu_K \rangle \\
&= \langle d^*(f \times id)^* U_K, \mu_K \rangle \\
&= \sum_{\mu, \nu} c_{\nu\mu} \langle d^*(f^* \rho_\nu \times \beta_\mu), \mu_K \rangle
\end{aligned}$$

$$\begin{aligned}
&= \sum_{\mu, \nu} c_{\nu\mu} \langle f^* \rho_\nu \smile \beta_\mu, \mu_K \rangle \\
&= \sum_{\lambda, \mu, \nu} c_{\nu\mu} m_{\nu\lambda} \langle \alpha_\lambda \smile \beta_\mu, \mu_K \rangle \\
&= \sum_{\lambda, \mu, \nu} (-1)^{(n-1) \deg \rho_\nu} c_{\nu\mu} m_{\nu\lambda} \langle \beta_\mu \smile \alpha_\lambda, \mu_K \rangle \\
&= \sum_{\lambda, \mu, \nu} (-1)^{(n-1) \deg \rho_\nu} c_{\nu\mu} m_{\nu\lambda} y_{\mu\lambda}.
\end{aligned}$$

Consequently we obtain  $I(f) = \Lambda((f|K)^*)$ . Since  $\Lambda((f|K)^*) = \Lambda((f|K)_*)$  is obvious, we have the desired result. q.e.d.

A topological manifold which is orientable (over  $\mathbf{Z}$ ) is orientable over  $\mathbf{Q}$ , and  $I(f)$  for  $R = \mathbf{Z}$  coincides with  $I(f)$  for  $R = \mathbf{Q}$ . Therefore Theorem D implies Theorem C.

Lemma 4 shows that  $I(f)$  coincides with  $I_f$  due to Dold when  $M = \mathbf{R}^n$ . Therefore Theorem C implies Theorem A. It is clear that Theorem C implies Theorem B.
