# ON THE K-THEORY OF PE 6 

Haruo MINAMI

(Received June 16, 1994)

## Introduction

Let $E_{6}$ be the exceptional compact simply-connected simple Lie group and let $P E_{6}$ be the projective group associated with $E_{6}$. In other words $P E_{6}=E_{6} / Z\left(E_{6}\right)$ with $Z\left(E_{6}\right) \cong Z / 3$ where $Z\left(E_{6}\right)$ denotes the center of $E_{6}$. The complex $K$-group $K^{*}\left(P E_{6}\right)$ of $P E_{6}$ has been calculated by Held and Suter in [5] and by Hodgkin in [7] independently. In this paper we calculate the real $K$-group $K O *\left(P E_{6}\right)$ of $P E_{6}$. To our aim, however, we begin with the computation of $K^{*}\left(P E_{6}\right)$ by a different method from [5, 7] and we compute $K O^{*}\left(P E_{6}\right)$ by applying the techniques parallel to $K^{*}\left(P E_{6}\right)$ and using some results obtained in course of calculation as well as the result on $K^{*}\left(P E_{6}\right)$.

We study these $K$-groups along the way of getting the $K$-groups of $P E_{7}$ in [10]. In the case of $E_{7}$ we used the $\boldsymbol{Z} / 2$-equivariant $K$-theories because of $Z\left(E_{7}\right) \cong \boldsymbol{Z} / 2$. In the present case we make use of the $\boldsymbol{Z} / 3$-equivariant $K$-theories and we reduce the structures of the $K$-groups of $P E_{6}$ to those of $K$-groups of $E_{6}$ and $L^{n}(3)$, the usual lens spaces, for $1 \leq n \leq 6$. We refer to [6, 12] for information about the $K$-groups of $E_{6}$.

In Section 1 we review some basic materials and give the ring structures of $K$-groups of the relevant lens spaces. In Section 2 and in Sections 3, 4 we determine the structures of $K^{*}\left(P E_{6}\right)$ and $K O^{*}\left(P E_{6}\right)$ respectively. The main results are Theorems 2.1 and 3.1.

The author wishes to express his gratitude to Professor Z. Yosimura who offered helpful advices for the computaion of $K O^{*}\left(L^{n}(3)\right)$.

## 1. Preliminaries

By $\Gamma$ we denote the center of $E_{6}$ which is a cyclic group of order 3 and set

$$
\Gamma=\left\{\gamma \mid \gamma^{3}=1\right\} .
$$

Consider the symmetric pair ( $E_{6}, \operatorname{Spin}(10) \cdot S^{1}$ ) with the subgroup of maximal rank. Then we see that $\Gamma$ coincides with the central subgroup of $S^{1} \subset \operatorname{Spin}(10) \cdot S^{1}$ or order 3 .

According to [13] we have the following irreducible representations

$$
\rho: E_{6} \rightarrow U(78), \rho_{1}: E_{6} \rightarrow U(27) \text { and } \rho_{1}^{*}: E_{6} \rightarrow U(27)
$$

where $\rho_{1}^{*}$ denotes the complex conjugate of $\rho_{1}$ and $\rho$ the adjoint representation of $E_{6}$. Moreover

$$
\operatorname{Ker} \rho=\Gamma \quad \text { and } \quad \operatorname{Ker} \rho_{1}=\operatorname{Ker} \rho_{1}^{*}=\{1\} .
$$

And the fundamental representations of $E_{6}$ are $\rho, \rho_{1}, \lambda^{2} \rho_{1}, \lambda^{3} \rho_{1}\left(=\lambda^{3} \rho_{1}^{*}\right), \lambda^{2} \rho_{1}^{*}$ and $\rho_{1}^{*}$, in which in particular $\rho$ and $\lambda^{3} \rho_{1}$ are the complexification of real representations. The same symbols $\rho$ and $\lambda^{3} \rho_{1}$ are used to denote also these real representations hereafter.

By Lemma of [9] (see also [1], Chap. 10) we have
(1.1) The restrictions of the fundamental representations to $\operatorname{Spin}(10) \cdot S^{1}$ are

$$
\begin{aligned}
& \rho=\lambda^{2} \rho_{10} \otimes 1+\Delta^{+} \otimes t^{3}+\Delta^{-} \otimes t^{-3}+1, \\
& \rho_{1}=1 \otimes t^{4}+\Delta^{-} \otimes t+\rho_{10} \otimes t^{-2}, \\
& \lambda^{2} \rho_{1}=\Delta^{-} \otimes t^{5}+\lambda^{3} \rho_{10} \otimes t^{2}+\rho_{10} \otimes t^{2}+\Delta^{-} \rho_{10} \otimes t^{-1}+\lambda^{2} \rho_{10} \otimes t^{-4}, \\
& \lambda^{3} \rho_{1}= \\
& \quad \lambda^{3} \rho_{10} \otimes t^{6}+\lambda^{3} \rho_{10} \otimes t^{-6}+\Delta^{+} \lambda^{2} \rho_{10} \otimes t^{3}+\Delta^{-} \lambda^{2} \rho_{10} \otimes t^{-3} \\
& \quad+\rho_{10} \lambda^{3} \rho_{10} \otimes 1+\lambda^{2} \rho_{10} \otimes 1
\end{aligned}
$$

and
where $\rho_{10}$ and $t$ are the canonical non-trivial 10- and 1-dimensional representations of $\operatorname{Spin}(10)$ and $S^{1}$ respectively, and $\Delta^{ \pm}$are the half-spin representations of $\operatorname{Spin}(10)$. The restrictions of $\rho_{1}^{*}$ and $\lambda^{2} \rho_{1}^{*}$ are immediate from (1.1) since ( $\left.\Delta^{ \pm}\right)^{*}=\Delta^{\mp}$.

Let $V$ be the representation space of the canonical non-trivial complex 1-dimensional representation of $\Gamma$. We write $n V$ for the direct sum of $n$ copies of $V$. Let $B\left(n V \oplus C^{k}\right)$ and $S\left(n V \oplus C^{k}\right)$ denote the unit ball and unit sphere in $n V \oplus C^{k}$ centered at the origin $o$, and let $\Sigma^{n V+2 k}=B\left(n V \oplus C^{k}\right) / S\left(n V \oplus C^{k}\right)$ with the collapsed $S\left(n V \oplus C^{k}\right)$ as base point. And then the lens space $L^{n}(3)$ is defined to be the orbit space $S((n+1) V) / \Gamma$.

Let $n V$ be embedded in $(n+k) V=n V \oplus k V$ by the assignment $v \mapsto(v, 0)$. Then there is an equivariant homeomorphism $S((n+k) V) / S(n V) \approx \Sigma^{n V} \wedge S(k V)_{+}$via which these spaces are identified below. For our computation we use mainly the following exact sequences, which are obtained from applying the equivariant $K$-functor to the cofibrations

$$
S(n V) \times X \xrightarrow{i} B(n V) \times X \xrightarrow{j} \Sigma^{n V} \wedge X_{+}
$$

and

$$
S(n V) \times X \xrightarrow{i} S((n+k) V) \times X \xrightarrow{j} \Sigma^{n V} \wedge(S(k V) \times X)_{+}
$$

where $i$ 's and $j$ 's are the canonical inclusions and projections and $Y_{+}$denotes the disjoint union of a $\Gamma$-space $Y$ and a point.

$$
\begin{equation*}
\text { (i) } \cdots \rightarrow \tilde{h}_{\Gamma}^{*}\left(\Sigma^{n V} \wedge X_{+}\right) \xrightarrow{j^{*}} h_{\Gamma}^{*}(B(n V) \times X) \xrightarrow{i^{*}} h_{\Gamma}^{*}(S(n V) \times X) \xrightarrow{\delta} \tag{1.2}
\end{equation*}
$$

$$
\tilde{h}_{\Gamma}^{*}\left(\Sigma^{n V} \wedge X_{+}\right) \rightarrow \cdots
$$

and

$$
\text { (ii) } \begin{aligned}
\cdots & \rightarrow \tilde{h}_{\Gamma}^{*}\left(\Sigma^{n V} \wedge(S(k V) \times X)_{+}\right) \xrightarrow{j^{*}} h_{\Gamma}^{*}(S((n+k) V) \times X) \xrightarrow{i^{*}} h_{\Gamma}^{*}(S(n V) \times X) \\
& \xrightarrow[\rightarrow]{\boldsymbol{\rightarrow}} \tilde{h}_{\Gamma}^{*}\left(\Sigma^{n V} \wedge(S(k V) \times X)_{+}\right) \rightarrow \cdots
\end{aligned}
$$

for $h=K, K O$, in which there holds $\delta\left(x i^{*}(y)\right)=\delta(x) y$.
If $X$ is a compact free $\Gamma$-space then we have a canonical isomorphism $h^{*}(X / \Gamma) \cong h_{\Gamma}^{*}(X)$ which we identify in the following.

Especially we consider (1.2) (ii) when $k=1$ and $X=$ a point, $E_{6}$. Then we have a homeomorphism

$$
\varphi:\left(\Sigma^{n V} \wedge(S(V) \times X)_{+}\right) / \Gamma \approx \Sigma^{2 n} \wedge\left(S^{1} \times X\right)_{+}
$$

arising from the map from $B(n V) \times S(V) \times X$ to $B\left(C^{n}\right) \times S^{1} \times X$ given by the assignment $\left(\left(z_{1}, \cdots, z_{n}\right), z, x\right) \mapsto\left(\left(z^{-1} z_{1}, \cdots, z^{-1} z_{n}\right), z^{3}, z^{-1} x\right)$ where $z^{-1} x$ is $x$ if $X=$ a point and denotes the product of $z^{-1}$ and $x$ in $E_{6}$ if $X=E_{6}$, under the identification $S(V)=S^{1}$, the circle subgroup of $E_{6}$ which is a factor of $\operatorname{Spin}(10) \cdot S^{1}$ stated above. Therefore we see that (1.2) (ii) yields the following exact sequence

$$
\begin{equation*}
\cdots \rightarrow h^{*}\left(S^{1} \times X\right) \xrightarrow{J} h_{\Gamma}^{*}(S((n+1) V) \times X) \xrightarrow{i^{*}} h_{\Gamma}^{*}(S(n V) \times X) \xrightarrow{\bar{\delta}} h^{*}\left(S^{1} \times X\right) \rightarrow \cdots \tag{1.3}
\end{equation*}
$$

for $X=$ a point, $E_{6}$, in which $J=j^{*} \varphi^{*}, \delta=\varphi^{*-1} \delta$ (up to the suspension isomorphism) and so there holds $\bar{\delta}\left(x i^{*}(y)\right)=\bar{\delta}(x) y$.

For later use we write $A \cdot g$ for the module over a ring $A$ generated by $g$. We recall from [11] the Thom isomorphism theorem in complex $K$-theory. Let $\mu \in \tilde{K}\left(S^{2}\right)$ be the Bott element. Then $\tilde{K}\left(S^{2 n}\right)=\boldsymbol{Z} \cdot \mu^{n}$ and we have by [11] the following.
(1.4) There exists an element $\tau_{n V}$ of $\tilde{K}_{r}\left(\Sigma^{n V}\right)$ such that multiplication by $\tau_{n V}$, $x \mapsto \tau_{n V} \wedge x$, induces an isomorphism $K_{I}^{*}(X) \cong \tilde{K}_{\Gamma}^{*}\left(\Sigma^{n V} \wedge X_{+}\right)$for any $\Gamma$-space $X$, the restriction of $\tau_{n V}$ to $K_{\Gamma}(o)=R(\Gamma)$ is $(1-V)^{n}$ and forgetting action $\tau_{n V}$ becomes $\mu^{n}$, where $R(\Gamma)$ is the complex representation ring of $\Gamma$.

As is well known, given a map $f: X \rightarrow U(n)$ (resp. $O(n)$ ), the homotopy class of the composite of this with an inclusion $U(n) \subset U$ (resp. $O(n) \subset O$ ) can be viewed as an element of $K^{-1}(X)$ (resp. $\left.K O^{-1}(X)\right)$ for which $\beta(f)$ we write in any case where $U($ resp. $O$ ) is the infinite unitary (resp. orthogonal) group. According to [6], then

$$
\begin{equation*}
K^{*}\left(E_{6}\right)=\Lambda\left(\beta(\rho), \beta\left(\rho_{1}\right), \beta\left(\lambda^{2} \rho_{1}\right), \beta\left(\lambda^{3} \rho_{1}\right), \beta\left(\lambda^{2} \rho_{1}^{*}\right), \beta\left(\rho_{1}^{*}\right)\right) \quad \text { as a ring. } \tag{1.5}
\end{equation*}
$$

When we deal with the real $K$-theory, we consider the complex $K$-theory to be $\boldsymbol{Z} / 8$-graded. The coefficient ring of each theory is given by $K O^{*}(+)=$ $Z\left[\eta_{1}, \eta_{4}\right] /\left(2 \eta_{1}, \eta_{1}^{3}, \eta_{1} \eta_{4}, \eta_{4}^{2}-4\right)$ where $\eta_{i} \in K O^{-i}(+)$ and $K^{*}(+)=Z[\mu] /\left(\mu^{4}-1\right)(+=$ point). Let us denote by $r$ and $c$ the realification and complexification homomorphisms as usual. In [12], Theorem $5.6 \mathrm{KO}\left(E_{6}\right)$ is determined by using (1.5) as follows.
(1.6) There exist elements $\lambda_{1}, \lambda_{2} \in K O^{0}\left(E_{6}\right)$ such that $c\left(\lambda_{1}\right)=\mu^{3} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right), c\left(\lambda_{2}\right)$ $=\mu^{3} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)$ and as a $K O^{*}(+)$-module

$$
K O^{*}\left(E_{6}\right)=F \oplus r(T)
$$

Here $F$ is the subalgebra of $K^{*}\left(E_{6}\right)$ generated by

$$
\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right), \lambda_{1}, \lambda_{2}
$$

and is a free $K O^{*}(+)$-module, and $T$ is the submodule of $K^{*}\left(E_{6}\right)$ generated by the monomials

$$
\begin{gathered}
\boldsymbol{n} \beta\left(\rho_{1}\right), \boldsymbol{n} \beta\left(\lambda^{2} \rho_{1}\right), \boldsymbol{n} \beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}\right), \\
\boldsymbol{n} \beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right), \boldsymbol{n} \beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right), \boldsymbol{n} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)
\end{gathered}
$$

where $n$ is a monomial in $\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right)$ with coefficients in $K^{*}(+)$. Further, $\lambda_{1}^{2}=\lambda_{2}^{2}=0$, and $\beta(\rho)^{2}$ and $\beta\left(\lambda^{3} \rho_{1}\right)$ are divisible by $\eta_{1}$.

Remarks 1. In fact it follows from the square formula of [4], §6 that $\beta(\rho)^{2}=\eta_{1}\left(\beta\left(\lambda^{2} \rho\right)+78 \beta(\rho)\right)$ and $\beta\left(\lambda^{3} \rho_{1}\right)^{2}=\eta_{1}\left(\beta\left(\lambda^{2}\left(\lambda^{3} \rho_{1}\right)\right)+27 \beta\left(\lambda^{3} \rho_{1}\right)\right)$. And we have $\lambda^{2} \rho=\lambda^{3} \rho_{1}+\rho$ by (1.1), so that $\beta(\rho)^{2}=\eta_{1}\left(\beta\left(\lambda^{3} \rho_{1}\right)+\beta(\rho)\right)$. Using $\eta_{1} r(x)=0$ stated in the subsequent remark we see that $\eta_{1} \beta\left(\lambda^{2}\left(\lambda^{3} \rho_{1}\right)\right)$ is only a linear combination of $\eta_{1} \beta\left(\lambda^{3} \rho_{1}\right)$ and $\eta_{1} \beta(\rho)$, and further observation of the restriction of $\lambda^{2}\left(\lambda^{3} \rho_{1}\right)$ to $\operatorname{Spin}(10) \cdot S^{1}$ leads to $\eta_{1} \beta\left(\lambda^{2}\left(\lambda^{3} \rho_{1}\right)\right)=0$ which therefore implies $\beta\left(\lambda^{3} \rho_{1}\right)^{2}=\eta_{1} \beta\left(\lambda^{3} \rho_{1}\right)$. As is noted in [12] all the other relations can be easily obtained from making use of the equality

$$
r(x) r(y)=r(x c r(y))=r(x y)+r\left(x y^{*}\right) \text { for } x, y \in T
$$

where $y^{*}$ denotes the complex conjugate of $y$.
2. The elements $\lambda_{1}, \lambda_{2}$ described above are unique. For example, if there exists another element $\lambda_{1}^{\prime}$ such that $c\left(\lambda_{1}\right)=c\left(\lambda_{1}^{\prime}\right)$ then, considering the Bott exact sequence

$$
\cdots \rightarrow K O^{*}\left(E_{6}\right) \xrightarrow{x} K O^{*}\left(E_{6}\right) \xrightarrow{c} K^{*}\left(E_{6}\right) \xrightarrow{\delta} \cdots
$$

where $\chi$ is multiplication by $\eta_{1}$ and $\delta$ is given by $\delta(\mu x)=r(x)$ [2], we see that $\lambda_{1}^{\prime}-\lambda_{1}$ can be written as $\lambda_{1}^{\prime}-\lambda_{1}=\eta_{1} a$ for some $a \in K^{-7}\left(E_{6}\right)$. But we may assume
that $a \in F$ because of $\chi \delta=0$ and the odd dimensional generators of $F$ are only $\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right)$. Hence we see that $a$ is divisible by $\eta_{1}^{2}$, so that $\eta_{1} a$ must be zero. This is quite similar to $\lambda_{2}$.

We next recall the Bott element of the equivariant $K O$-theory associated with $\Gamma$. Let $W=r(V)$, the realification of $V$, and we write $n W$ to denote the direct sum of $n$ copies of $W$ as before. We show that $W \oplus W$ is provided with a Spin $\Gamma$-module structure. It suffices to prove that the composite homomorphism $i: \Gamma \rightarrow U(1) \rightarrow S O(2) \xrightarrow{d} S O(2) \times S O(2) \rightarrow S O(4)$, where the unlabelled arrows are canonical inclusions and $d$ is the diagonal map, may be lifted to a homomorphism $\tilde{i}$ from $\Gamma$ to $\operatorname{Spin}(4)$, satisfying $\pi \tilde{i}=i$ where $\pi$ denotes the canonical projection from $\operatorname{Spin}(4)$ to $S O(4)$. Now we see that the map $\gamma \mapsto\left(\cos \frac{\pi}{3}+e_{1} e_{2} \sin \frac{\pi}{3}\right)\left(\cos \frac{\pi}{3}+e_{3} e_{4} \sin \frac{\pi}{3}\right)$, where $e_{1}, \cdots, e_{4}$ is an orthonormal basis of $R^{4}$ such that $e_{i}^{2}=-1, e_{i} e_{j}=-e_{j} e_{i}$ if $i \neq j$, defines a required lifting $\tilde{i}$. So we see further that $2 n W$ in general can be provided with a Spin $\Gamma$-module structure. To state the Thom isomorphism theorem in the equivariant $K O$-theory moreover we need the following fact [11].
(1.7) Let $X$ be a compact trivial $\Gamma$-space. Then for a real $\Gamma$-vector bundle $E$ over $X$ the assignment $E \mapsto \operatorname{Hom}_{I}(X \times R, E) \oplus W \otimes_{C} \operatorname{Hom}(X \times W, E)$ induces an isomorphism

$$
K O_{\Gamma}^{*}(X) \cong K O^{*}(X) \oplus Z \cdot W \otimes K^{*}(X)
$$

where $\boldsymbol{C}$ is identified with $\operatorname{Hom}_{\Gamma}(W, W)$ normally. In fact the 2 nd direct summand of this equality is equal to $r\left(Z \cdot V \otimes K^{*}(X)\right)$.

From [3] we then have
(1.8) There is an element $\tau_{(4 n+2 \varepsilon) W+4 \varepsilon} \in \widetilde{K O}_{I}\left(\Sigma^{(4 n+2 \varepsilon) V+4 \varepsilon}\right)$ for $\varepsilon=0,1$ such that the assignment $x \mapsto \tau_{(4 n+2 \varepsilon) W+4 \varepsilon} \wedge x$ induces an isomorphism $K O_{F}^{*}(X) \cong K O_{F}^{*}\left(\Sigma^{(4 n+2 \varepsilon) V+4 \varepsilon}\right.$ $\left.\wedge X_{+}\right)$for any $\Gamma$-space $X$ and the restriction of $\tau_{(4 n+2 \varepsilon) W+4 \varepsilon}$ to $\widetilde{K O}_{\Gamma}\left(\Sigma^{4 \varepsilon}\right)$ $=\boldsymbol{Z} \cdot \eta_{4}^{\varepsilon} \oplus \boldsymbol{Z} \cdot W \mu^{2 \varepsilon}$ is $3^{n}(r(V-1))^{n}\left(r\left(\mu^{2}-V \mu^{2}\right)\right)^{\varepsilon}$.

Finally we mention the structure of the $K$-groups of lens spaces $L^{n}(3)$ for $1 \leq n \leq 6$. This can be obtained by easy calculations using (1.3) when $X=\mathrm{a}$ point. As for the 0 -terms it can be found in [8] for any lens space $L^{n}(p)$ with $p$, prime. But the technique used here is essential for our computation in the following sections. In order to describe the results we introduce the ring generators. By $\xi_{n}$ we denote the complex line bundle $S((n+1) V) \times{ }_{\Gamma} V \rightarrow L^{n}(3)$. And we set

$$
\sigma_{n}=\xi_{n}-1 \in \tilde{K}\left(L^{n}(3)\right) \quad \text { and } \quad \bar{\sigma}_{n, i}=r\left(\mu^{i} \sigma_{n}\right) \in \widetilde{K O}^{-2 i}\left(L^{n}(3)\right) .
$$

Let $p$ be the composite $L^{n}(3) \rightarrow L^{n}(3) /\left(L^{n}(3)-N\right) \approx S^{2 n+1}$ of canonical projection and homeomorphism where $N$ is a coordinates neighborhood of some element of $L^{n}(3)$.
Then we set

$$
v_{n}=p^{*}\left(l_{n}\right) \in \tilde{K}^{2 n+1}\left(L^{n}(3)\right) \quad \text { and } \quad \bar{v}_{n}=p^{*}\left(l_{n}\right) \in K \widetilde{O}^{2 n+1}\left(L^{n}(3)\right)
$$

where $p^{*}: \tilde{h}^{2 n+1}\left(S^{2 n+1}\right) \rightarrow \tilde{h}^{2 n+1}\left(L^{n}(3)\right)$ and $t_{n}$ denotes a generator of $\tilde{h}^{2 n+1}\left(S^{2 n+1}\right)$ $\cong Z$.

Observing the exact sequence (1.3) where $X=$ a point we see that
(1.9) $\bar{\delta}\left(v_{n-1}\right)=3 \in K^{0}\left(S^{1}\right)=\boldsymbol{Z} \cdot 1, J\left(l_{0}\right)=v_{n}$ (up to sign) and $J(1)=\left(-\sigma_{n}\right)^{n}$.

Forgetting the action of $\Gamma$, the $v_{n-1}$ and $\tau_{n V}$ become $3 l_{n-1}$ and $\mu^{n}$ respectively. So we have $\delta\left(v_{n-1}\right)=3 \tau_{n V} \wedge 1$ (up to sign), so that the 1st formula follows. The 2nd formula is immediate from the definition of $v_{n-1}$ and the 3rd also follows from (1.4) immediately. We ignore the sign below because it may be exchanged if necessary. Then from this it follows that
(1.10) $\bar{\delta}\left(\bar{v}_{n-1}\right)=3 \in K O^{0}\left(S^{1}\right)=\boldsymbol{Z} \cdot 1, J\left(t_{0}\right)=\bar{v}_{n}$ and $J\left(r\left(\mu^{i+n}\right)\right)=r\left(\mu^{i}\left(-\sigma_{n}\right)^{n}\right)$.

Making use of (1.3) when $X=$ a point together with these two facts (1.9), (1.10) we can get the following results inductively by taking $n$ in turn to be $0,1, \cdots, 6$.
(i) $\quad \tilde{K}^{0}\left(L^{n}(3)\right)=\boldsymbol{Z} / 3^{s+r} \cdot \sigma_{n} \oplus \boldsymbol{Z} / 3^{s} \cdot \sigma_{n}^{2}$ and $K^{-1}\left(L^{n}(3)\right)=\boldsymbol{Z} \cdot v_{n}$
for $0 \leq n \leq 6$ where $s=\left[\frac{n}{2}\right], r=\left((-1)^{n-1}+1\right) / 2$ and the ring structure is given by

$$
\sigma_{n}^{3}+3 \sigma_{n}^{2}+3 \sigma_{n}=0 \quad \text { and } \quad v_{n}^{2}=0
$$

(ii) $\quad \widetilde{K O}^{0}\left(L^{n}(3)\right)= \begin{cases}\boldsymbol{Z} / 3^{s} \cdot \bar{\sigma}_{n, 0} \oplus \boldsymbol{Z} / 2 \cdot \eta_{1} \bar{v}_{n} & (n=0,4) \\ \boldsymbol{Z} / 3^{s} \cdot \bar{\sigma}_{n, 0} & \text { (otherwise), }\end{cases}$

$$
\begin{aligned}
& \widetilde{K O}^{-1}\left(L^{n}(3)\right)= \begin{cases}\boldsymbol{Z} \cdot \eta_{4} \bar{v}_{n} & (n=1,5) \\
0 & (n=2,6) \\
\boldsymbol{Z} \cdot \bar{v}_{n} & (n=3) \\
\boldsymbol{Z} / 2 \cdot \eta_{1}^{2} \bar{v}_{n} & (n=0,4),\end{cases} \\
& K O^{-2}\left(L^{n}(3)\right)= \begin{cases}\boldsymbol{Z} / 3^{t} \cdot \bar{\sigma}_{n, 1} \oplus \boldsymbol{Z} / 2 \cdot \eta_{1} \bar{v}_{n} & (n=3) \\
\boldsymbol{Z} / 3^{t} \cdot \bar{\sigma}_{n, 1} & (\text { otherwise }),\end{cases} \\
& \widetilde{K O}^{-3}\left(L^{n}(3)\right)= \begin{cases}0 & (n=1,5) \\
\boldsymbol{Z} \cdot \bar{v}_{n} & (n=2,6) \\
\boldsymbol{Z} / 2 \cdot \eta_{1}^{2} \bar{v}_{n} & (n=3) \\
\boldsymbol{Z} \cdot \eta_{4} \bar{v}_{n} & (n=0,4),\end{cases} \\
& \widetilde{K O^{-4}\left(L^{n}(3)\right)}= \begin{cases}\boldsymbol{Z} / 3^{s} \cdot \bar{\sigma}_{n, 2} \oplus \boldsymbol{Z} / 2 \cdot \eta_{1} \bar{v}_{n} & (n=2,6) \\
\boldsymbol{Z} / 3^{s} \cdot \bar{\sigma}_{n, 2} & \text { (otherwise), }\end{cases}
\end{aligned}
$$

and

$$
\begin{aligned}
& \widetilde{K O}^{-5}\left(L^{n}(3)\right)= \begin{cases}\boldsymbol{Z} \cdot \bar{v}_{n} & (n=1,5) \\
\boldsymbol{Z} / 2 \cdot \eta_{1}^{2} \bar{v}_{n} & (n=2,6) \\
\boldsymbol{Z} \cdot \eta_{4} \bar{v}_{n} & (n=3) \\
0 & (n=0,4)\end{cases} \\
& \widetilde{K O^{-6}}\left(L^{n}(3)\right)= \begin{cases}\boldsymbol{Z} / 3^{t} \cdot \bar{\sigma}_{n, 3} \oplus \boldsymbol{Z} / 2 \cdot \eta_{1} \bar{v}_{n} & (n=1,5) \\
\boldsymbol{Z} / 3^{s} \cdot \bar{\sigma}_{n, 3} & (n=0,2,4,6) \\
\boldsymbol{Z} / 3^{t} \cdot \bar{\sigma}_{n, 3} & (n=3)\end{cases} \\
& \widetilde{K O^{-7}}\left(L^{n}(3)\right)= \begin{cases}\boldsymbol{Z} / 2 \cdot \eta_{1}^{2} \bar{v}_{n} & (n=1,5) \\
\boldsymbol{Z} \cdot \eta_{4} \bar{v}_{n} & (n=2,6) \\
0 & (n=3) \\
\boldsymbol{Z} \cdot \bar{v}_{n} & (n=0,4)\end{cases}
\end{aligned}
$$

for $0 \leq n \leq 6$ where $s=\left[\frac{n}{2}\right], t=\left[\frac{n+1}{2}\right]$ and the ring structure is given by

$$
\begin{gathered}
\bar{\sigma}_{n, i} \bar{\sigma}_{n, j}=\left((-1)^{i+j}+(-1)^{i+1}+(-1)^{j+1}-2\right) \bar{\sigma}_{n, i+j}+\left((-1)^{i+j}+(-1)^{i+1}+(-1)^{j}\right. \\
-1) r\left(\mu^{i+j}\right) \\
\eta_{4} \bar{\sigma}_{n, i}=2 \bar{\sigma}_{n, i+2} \text { and } \bar{v}_{n}^{2}=0 .
\end{gathered}
$$

## 2. The complex $K$-group of $\mathrm{PE}_{6}$

In this section we give the structure of $K^{*}\left(P E_{6}\right)$.
We denote a canonical complex line bundle $E_{6} \times{ }_{\Gamma} V \rightarrow P E_{6}$ by $\xi$ and set

$$
\sigma=\xi-1 \in K\left(P E_{6}\right) .
$$

Since $\rho$ and $\lambda^{3} \rho_{1}$ are trivial on $Z\left(E_{6}\right)=\Gamma$, these can be regarded as representations of $P E_{6}$ and so the elements

$$
\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right) \in K^{-1}\left(P E_{6}\right)
$$

can be defined in the manner as mentioned in the preceding section. From (1.1) we see that $\rho_{1}(\gamma)$ is a $27 \times 27$ scalar matrix with all diagonal entries $\omega=\exp \left(\frac{2 \pi i}{3}\right)$ where $\gamma \in \Gamma$. Hence it follows that the assignments $g \mapsto \rho_{1}^{*}(g) \rho_{1}(g), g \mapsto \lambda^{2} \rho_{1}(g) 13 \rho_{1}(g)$ and $g \mapsto \lambda^{2} \rho_{1}^{*}(g) 13 \rho_{1}^{*}(g)$ induce three maps from $P E_{6}$ to $U$ where $g \in E_{6}$. We denote also the homotopy classes of maps by

$$
\beta\left(\rho_{1}+\rho_{1}^{*}\right), \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right), \beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right) \in K^{-1}\left(P E_{6}\right)
$$

respectively. In order to describe the result we need one more element. Let $N$ be the representation space of the (regular) representation $\Gamma \rightarrow S O(3)$ of $N$ given by the assignment

$$
\gamma \mapsto\left(\begin{array}{lll}
0 & 0 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{array}\right)
$$

and put $F=E_{6} \times C^{27} \otimes N$ which is viewed as a product bundle over $E_{6}$. We define a $\Gamma$-equivariant bundle isomorphism $f: F \rightarrow F$ by the assignment $\left(g,\left(v_{1}, v_{2}, v_{3}\right)\right)$ $\mapsto\left(g,\left(\rho_{1}\left(\gamma^{2} g\right) v_{1}, \rho_{1}(\gamma g) v_{2}, \rho_{1}(g) v_{3}\right)\right)$. Then $f$ defines an element of $K_{\Gamma}^{-1}\left(E_{6}\right)$ in the usual way, which we denote by

$$
\beta\left(\rho_{1}, \Gamma\right) \in K_{\Gamma}^{-1}\left(E_{6}\right)=K^{-1}\left(P E_{6}\right) .
$$

In fact, this coincides with $t\left(\beta\left(\rho_{1}\right)\right)$ where $t: K^{-1}\left(E_{6}\right) \rightarrow K_{I}^{-1}\left(E_{6}\right)$ is the transfer map.
Then we have

Theorem 2.1 ([5, 7]). With the notation as above

$$
\begin{gathered}
K^{*}\left(P E_{6}\right)=\Lambda\left(\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right), \beta\left(\rho_{1}+\rho_{1}^{*}\right), \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right), \beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right), \beta\left(\rho_{1}, \Gamma\right)\right) \\
\otimes P /\left(\beta\left(\rho_{1}, \Gamma\right) \sigma\right)
\end{gathered}
$$

as a ring. Here $P$ is the subring of $K^{*}\left(P E_{6}\right)$ generated by $\sigma$ such that

$$
P \cong Z \cdot 1 \oplus Z / 27 \cdot \sigma \oplus Z / 27 \cdot \sigma^{2}
$$

where the ring structure is given by

$$
\sigma^{3}+3 \sigma^{2}+3 \sigma=0 .
$$

We prepare a lemma for a proof of the theorem. According to (1.4) the restriction of $\tau_{7 V} \in \tilde{K}_{\Gamma}\left(\Sigma^{7 V}\right)$ to $R(\Gamma)$ is $27(V-1)$. From this fact we see that $\tau_{7 V}$ yields an equivariant bundle isomorphim $\alpha$ from $S(7 V) \times E_{6} \times(27 V \oplus S)$ to $S(7 V) \times E_{6}$ $\times\left(C^{27} \oplus S\right)$ for some $\Gamma$-module $S$. On the other hand, $\rho_{1}$ induces an equivariant bundle isomorphism $f$ from $S(7 V) \times E_{6} \times\left(C^{27} \oplus S\right)$ to $S(7 V) \times E_{6} \times(27 V \oplus S)$ given by $f(x, g,(u, v))=\left(x, g,\left(\rho_{1}(g) u, v\right)\right)$. Then, in the usual way, the composite $\alpha f$ defines an element of $K_{r}^{-1}\left(S(7 V) \times E_{6}\right)=K^{-1}\left(S(7 V) \times{ }_{r} E_{6}\right)$ which we denote by $\widetilde{\beta}\left(\rho_{1}\right)$. Similarly, by taking $\lambda^{2} \rho_{1}$ and $\lambda^{2} \alpha, \rho_{1}^{*}$ and $\alpha^{*}$, and $\lambda^{2} \rho_{1}^{*}$ and $\lambda^{2} \alpha^{*}$ instead of $\rho_{1}$ and $\alpha$ respectively we get the elements $\widetilde{\beta}\left(\lambda^{2} \rho_{1}\right), \widetilde{\beta}\left(\rho_{1}^{*}\right), \widetilde{\beta}\left(\lambda \rho_{1}^{*}\right) \in K_{r}^{-1}\left(S(7 V) \times E_{6}\right)$. Also we denote by the same symbols the restrictions of these elements to $K_{\Gamma}^{-1}\left(S(n V) \times E_{6}\right)$ for $1 \leq n \leq 6$.

Let $\pi_{1}$ (resp. $\pi_{2}$ ) denote the projection from $S(n V) \times E_{6}$ to the 1st (resp. 2nd) factor. Put $\widetilde{\beta}(\rho)=\pi_{2}^{*}(\beta(\rho)), \widetilde{\beta}\left(\lambda^{3} \rho_{1}\right)=\pi_{2}^{*}\left(\beta\left(\lambda^{3} \rho_{1}\right)\right), \quad \tilde{\sigma}=\pi_{1}^{*}\left(\sigma_{n-1}\right)=\pi_{2}^{*}(\sigma)$ and $\bar{v}_{n-1}$ $=\pi_{2}^{*}\left(v_{n-1}\right)$.

Then we have

Lemma 2.2. With the notation as above

$$
K_{\Gamma}^{*}\left(S((n+1) V) \times E_{6}\right)=P_{n} \otimes \Lambda_{n} /\left(\tilde{\sigma} \otimes \tilde{v}_{n}\right)
$$

as a ring for $0 \leq n \leq 6$. Here $P_{n}$ is the subring generated by $\tilde{\sigma}$ such that

$$
P_{n}=Z \cdot 1 \oplus Z / 3^{s+t} \cdot \tilde{\sigma} \oplus Z / 3^{s} \cdot \tilde{\sigma}^{2}
$$

where $s=\left[\frac{n}{2}\right], r=\left((-1)^{n-1}+1\right) / 2$ and the ring structure is given by

$$
\tilde{\sigma}^{3}+3 \tilde{\sigma}^{2}+3 \tilde{\sigma}=0,
$$

and

$$
\Lambda_{n}=\Lambda\left(\widetilde{\beta}(\rho), \widetilde{\beta}\left(\rho_{1}\right), \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right), \widetilde{\beta}\left(\lambda^{3} \rho_{1}\right), \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right), \widetilde{\beta}\left(\rho_{1}^{*}\right), \tilde{v}_{n}\right) .
$$

In other words,

$$
K^{*}\left(S((n+1) V) \times E_{6}\right) \cong \Lambda\left(\widetilde{\beta}(\rho), \widetilde{\beta}\left(\rho_{1}\right), \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right), \widetilde{\beta}\left(\lambda^{3} \rho_{1}\right), \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right), \widetilde{\beta}\left(\rho_{1}^{*}\right)\right) \otimes K^{*}\left(L^{n}(3)\right)
$$

as a ring canonically.
Proof. For a proof we make use of (1.3) when $X=E_{6}$ and we show this inductively on $n$. In this case the exact sequence (1.3) is as follows.

$$
\cdots \rightarrow K^{*}\left(S^{1} \times E_{6}\right) \xrightarrow{J} K_{I}^{*}\left(S((n+1) V) \times E_{6}\right) \xrightarrow{i^{\star}} K_{\Gamma}^{*}\left(S(n V) \times E_{6}\right) \xrightarrow{\bar{\delta}} \cdots
$$

in which the maps satisfy $\bar{\delta}\left(x i^{*}(y)\right)=\bar{\delta}(x) y$. Furthermore we see by (1.9) that there hold the equalities $\bar{\delta}\left(\tilde{v}_{n-1}\right)=3, J\left(t_{0} \times 1\right)=\tilde{v}_{n}$ and $J(1)=(-\tilde{\sigma})^{n}$. We now check the 1st stage of our induction. Because $S(V)$ may be viewed as a $\Gamma$-invariant subspace of $E_{6}$ as noted in the preceding of (1.3), it follows that $S(V) \times{ }_{r} E_{6} \approx S^{1} \times E_{6}$ which is induced by the assignment $(z, g) \mapsto\left(z^{3}, z^{-1} g\right)$ where $z \in S(V)$ and $g \in E_{6}$, and so

$$
\begin{aligned}
K_{\Gamma}^{*}\left(S(V) \times E_{6}\right) & \cong K^{*}\left(S^{1} \times E_{6}\right) \\
& \cong \Lambda\left(t_{0}\right) \otimes \Lambda\left(\beta(\rho), \beta\left(\rho_{1}\right), \beta\left(\lambda^{2} \rho_{1}\right), \beta\left(\lambda^{3} \rho_{1}\right), \beta\left(\lambda^{2} \rho_{2}^{*}\right), \beta\left(\rho_{1}^{*}\right)\right)
\end{aligned}
$$

by (1.5).
We consider the elements of $K_{I}^{*}\left(S(V) \times E_{6}\right)$ corresponding to the generators of $K^{*}\left(S^{1} \times E_{6}\right)$ via this isomorphism. By definition we see that $\widetilde{\beta}\left(\rho_{1}\right)$ of $K_{\Gamma}^{*}\left(S(V) \times E_{6}\right)$ can be decomposed into the form $\beta\left(\rho_{1}\right)+n \mu$ for some $n \in \boldsymbol{Z}$ via this isomorphism where $n \mu$ is constructed with $\rho_{1} \mid S^{1}$ and $\alpha$ described in the preceding of Lemma 2.2. Now as mentioned above $\alpha$ arises from $\tau_{7 V}$ and $\rho_{1} \mid S^{1}=t^{4}+16 t+10 t^{-2}$ which follows from the 2 nd formula of (1.1). So we get the case when $n=0$ by an inspection of the construction of $\widetilde{\beta}\left(\rho_{1}\right)$. For the same reasons the $\widetilde{\beta}(a)$ 's correspond to $\beta(a)$ 's respectively. In particular, it is immediate as for $a=\rho, \lambda^{3} \rho_{1}$. And also it is straightforward that $\tilde{v}_{0}$ corresponds to $l_{0}$ up to sign. Hence we conclude that

$$
K_{\Gamma}^{*}\left(S(V) \times E_{6}\right)=\Lambda_{0}\left(=P_{0} \otimes \Lambda_{0} /\left(\tilde{\sigma} \otimes \tilde{v}_{0}\right)\right) .
$$

For the next stage of induction we observe the above exact sequence when $n=1$. Then clearly $i^{*}(\widetilde{\beta}(a))=\widetilde{\beta}(a), i^{*}(\tilde{\sigma})=0$ and from the discussion above it follows that

$$
\bar{\delta}\left(\tilde{v}_{0}\right)=3, J\left(l_{0} \times \boldsymbol{n}\right)=\tilde{v}_{1} \tilde{n} \text { and } J(\boldsymbol{n})=-\tilde{\sigma} \tilde{\boldsymbol{n}}
$$

where $\boldsymbol{n}$ is a monomial in $\beta(\rho), \beta\left(\rho_{1}\right), \beta\left(\lambda^{2} \rho_{1}\right), \beta\left(\lambda^{3} \rho_{1}\right), \beta\left(\lambda^{2} \rho_{1}^{*}\right), \beta\left(\rho_{1}^{*}\right)$ and $\tilde{\boldsymbol{n}}$ the monomial obtained by replacing by $\beta(a)$ 's by $\widetilde{\beta}(a)$ 's in $n$. Furthermore we have

$$
\bar{\delta}\left(\tilde{v}_{0} \boldsymbol{n}\right)=3 \tilde{\boldsymbol{n}}
$$

using the equality $\bar{\delta}\left(x i^{*}(y)\right)=\bar{\delta}(x) y$. By applying these formulas and the result for $S(V) \times E_{6}$ to the exact sequence above we can get $K_{\Gamma}^{*}\left(S(2 V) \times E_{6}\right)=P_{1} \otimes \Lambda_{1}$ $/\left(\tilde{\sigma} \otimes \tilde{v}_{1}\right)$. Similarly we see that the remaining stages of induction can be done in turn as in the computation of $K^{*}\left(L^{n}(3)\right)$.

From this result and (1.11) (i) we infer that the last isomorphism is given by using the canonical action of $K_{I}^{*}(S((n+1) V))$ on $K_{I}^{*}\left(S((n+1) V) \times E_{6}\right)$ induced by the external tensor product, and the proof is completed.

Proof of Theorem 2.1. According to (1.2) (i) where $X=E_{6}$ and $n=7$ we have an exact sequence

$$
\cdots \rightarrow \tilde{K}_{\Gamma}^{*}\left(\Sigma^{7 V} \wedge E_{6+}\right) \xrightarrow{j^{*}} K^{*}\left(P E_{6}\right) \xrightarrow{i^{*}} K_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right) \xrightarrow{\delta} \cdots
$$

Here we have $j^{*}\left(\tau_{7 V} \wedge 1\right)=27 \sigma$ by (1.3). But $\rho_{1}$ induces a bundle isomorphism $E_{6} \times{ }_{r} 27 V \cong P E_{6} \times C^{27}$ in a canonical way because $\rho_{1}(\gamma)$ is the $27 \times 27$ scalar matrix with entries $\omega=\exp \left(\frac{2 \pi i}{3}\right)$ where $\gamma$ is the generator of $\Gamma$. So $27 \sigma=0$ which implies $j^{*}=0$. Therefore the above exact sequence becomes the short exact sequence

$$
\begin{equation*}
0 \rightarrow K^{*}\left(P E_{6}\right) \xrightarrow{i^{*}} K_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right) \xrightarrow{\delta} K^{*}\left(P E_{6}\right) \rightarrow 0 . \tag{2.3}
\end{equation*}
$$

where $\delta$ also denotes the composition of the $\delta$ as above with the inverse of the Thom isomorphism.

Consider the images of the elements given in the beginning of this section by $i^{*}$. Then by an inspection of definition we have

$$
\begin{align*}
& \quad i^{*}(\sigma)=\tilde{\sigma}, i^{*}(\beta(\rho))=\widetilde{\beta}(\rho), i^{*}\left(\beta\left(\lambda^{3} \rho_{1}\right)\right)=\widetilde{\beta}\left(\lambda^{3} \rho_{1}\right)  \tag{2.4}\\
& i^{*}\left(\beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)=\widetilde{\beta}\left(\rho_{1}\right)+(\tilde{\sigma}+1) \widetilde{\beta}\left(\rho_{1}^{*}\right), i^{*}\left(\beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)\right) \\
& =13 \widetilde{\beta}\left(\rho_{1}\right)+(\tilde{\sigma}+1) \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right), i^{*}\left(\beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right)\right)=13 \widetilde{\beta}\left(\rho_{1}^{*}\right)+(\tilde{\sigma}+1)^{2} \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right)
\end{align*}
$$

and

$$
i^{*}\left(\beta\left(\rho_{1}, \Gamma\right)\right)=\left(\tilde{\sigma}^{2}+3 \tilde{\sigma}+3\right) \tilde{\beta}\left(\rho_{1}\right)-\tilde{v}_{6} .
$$

By these formulas and Lemma 2.2 when $n=6$ we see easily that the right-hand
side $R$ of the equality of Theorem 2.1 becomes a subalgebra of $K^{*}\left(P E_{6}\right)$, since $i^{*}$ is injective. Moreover by definition it follows that

$$
\begin{equation*}
\delta\left(\widetilde{\beta}\left(\rho_{1}\right)\right)=1 \quad \text { and } \quad \delta\left(\tilde{v}_{6}\right)=\tilde{\sigma}^{2}+3 \tilde{\sigma}+3 . \tag{2.5}
\end{equation*}
$$

Using (2.4), (2.5) together with the equality $\delta\left(x i^{*}(y)\right)=\delta(x) y$ we can verify easily that $R$ fills $K^{*}\left(P E_{6}\right)$, because of the surjectivity of $\delta$. This completes the proof of Theorem 2.1.

## 3. The real $K$-group of $P E_{6}$

In this section and the following we study the real $K$-group of $P E_{6}$. To begin with we recall the convention done in Section 1. The representations $\rho$ and $\lambda^{3} \rho_{1}$ of $E_{6}$ are indeed real and are trivial on the center of $E_{6}$. So we view these as real representations of $P E_{6}$ and for these the same notation is used. Furthermore the complex $K$-theory is regarded as a $Z / 8$-graded cohomology theory with the coefficient ring $K^{*}(+)=Z[\mu] /\left(\mu^{4}-1\right)$. Now we set

$$
\bar{\sigma}_{i}=r\left(\mu^{i} \sigma\right) \text { for } 0 \leq i \leq 3 .
$$

Then we have
Theorem 3.1. There exist elements $\left.\lambda, \bar{\lambda}_{1} \in \widetilde{K O}{ }^{(P E} E_{6}\right)$ such that $c(\lambda)=\mu^{3} \beta\left(13 \rho_{1}\right.$ $\left.+\lambda^{2} \rho_{1}\right) \beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right), c\left(\bar{\lambda}_{1}\right)=\mu^{3} \beta\left(\rho_{1}, \Gamma\right) \beta\left(\rho_{1}+\rho_{1}^{*}\right)$, and as a KO* $(+)$-module

$$
K O^{*}\left(P E_{6}\right)=P \otimes F \oplus r(T)
$$

Here

$$
P=\boldsymbol{Z} / 27\left[\bar{\sigma}_{0}, \bar{\sigma}_{1}, \bar{\sigma}_{2}, \bar{\sigma}_{3}\right] / I
$$

where I denotes the ideal of $\boldsymbol{Z} / 27\left[\bar{\sigma}_{0}, \bar{\sigma}_{1}, \bar{\sigma}_{2}, \bar{\sigma}_{3}\right]$ generated by

$$
\left.\bar{\sigma}_{i} \bar{\sigma}_{j}-\left((-1)^{i+j}+(-1)^{i+1}+(-1)^{j+1}-2\right) \bar{\sigma}_{i+j}-\left((-1)^{i+j}+(-1)^{i+1}+(-1)^{j}-1\right) r\left(\mu^{i+j}\right)\right),
$$

$F$ denotes the subalgebra of $K O^{*}\left(P E_{6}\right)$ generated by $\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right), \lambda, \lambda_{1}$, which is a free $K O^{*}(+)$-module, and $T$ the submodule in $K^{*}\left(P E_{6}\right)$ generated by the monomials

$$
\begin{gathered}
\boldsymbol{n} \beta\left(\rho_{1}, \Gamma\right), \boldsymbol{n} \beta\left(\rho_{1}+\rho_{1}^{*}\right), \boldsymbol{n} \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}^{*}\right), \boldsymbol{n} \beta\left(\rho_{1}, \Gamma\right) \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right), \\
\boldsymbol{n} \beta\left(\rho_{1}, \Gamma\right) \beta\left(\rho_{1}+\rho_{1}^{*}\right) \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right), \beta\left(\rho_{1}, \Gamma\right) \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right) \beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right)
\end{gathered}
$$

where $n$ is a monomial in $\sigma, \beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right)$ with coefficients in $K^{*}(+)$. Further, $\lambda^{2}=\bar{\lambda}_{1}^{2}=\bar{\sigma}_{i} \bar{\lambda}_{1}=0, \beta(\rho)^{2}=\eta_{1}\left(\beta\left(\lambda^{3} \rho_{1}\right)+\beta(\rho)\right)$ and $\beta\left(\lambda^{3} \rho_{1}\right)^{2}=\eta_{1} \beta\left(\lambda^{3} \rho_{1}\right)$.

Remark. All the other relations can be obtained from the relations in $K^{*}\left(P E_{6}\right)$, $K^{*}\left(L^{6}(3)\right)$ and $K O^{*}\left(L^{6}(3)\right)$ by using the equalities $r(x) r(y)=r(x y)+r\left(x y^{*}\right), r\left(x^{*}\right)=r(x)$
and (2.4). The following is a sample calculation. For $x \in T$

$$
\begin{aligned}
& r(x) r\left(\beta\left(\rho_{1}, \Gamma\right)\right)=\left(\bar{\sigma}_{0}+3\right) r\left(x \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right), r\left(x^{*} \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)=r\left((\sigma+1)^{2} x \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right), \\
& r\left(x \sigma \beta\left(\rho_{1}, \Gamma\right)\right)=0, \bar{\sigma}_{0} r\left(\mu^{i} \beta(\rho, \Gamma)\right)=0,\left(\bar{\sigma}_{0}+3\right) r\left(\mu^{i} \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)=0, i=1,3 \\
& \left(\bar{\sigma}_{0}+3\right) r\left(\beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)=2 r\left(\beta\left(\rho_{1}, \Gamma\right)\right),\left(\bar{\sigma}_{0}+3\right) r\left(\mu^{2} \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)=\eta_{4} r\left(\beta\left(\rho_{1}, \Gamma\right)\right) .
\end{aligned}
$$

We are now going to prove the theorem. The proof is done parallel to that of the complex case. However we have a difference between the complex and real cases in the real version of (2.3) for reasons of the real Thom isomorphism theorem.

Apply (1.2) (i) to $X=E_{6}, n=7$, then we have an exact sequence

$$
\cdots \rightarrow \widetilde{O}_{\Gamma}^{*}\left(\Sigma^{7 V} \wedge E_{6+}\right) \xrightarrow{j^{*}} K O^{*}\left(P E_{6}\right) \xrightarrow{i^{*}} K O_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right) \xrightarrow{\delta} \cdots
$$

Combining this with the Thom isomorphism (1.8) such that $\widetilde{K \tilde{O}_{I}^{k+4}\left(\Sigma^{V} \wedge E_{6+}\right)}$ $\cong \widetilde{K O_{I}^{k}}\left(\Sigma^{7 V} \wedge E_{6+}\right)$ gives the following.

Lemma 3.2. We have a short exact sequence

$$
0 \rightarrow K O^{*}\left(P E_{6}\right) \xrightarrow{i^{*}} K O_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right) \xrightarrow{\bar{\delta}} \widetilde{K O}_{\Gamma}^{*}\left(\Sigma^{V} \wedge E_{6+}\right) \rightarrow 0
$$

where $\bar{\delta}$ is the composite of $\delta$ with the inverse of the Thom isomorphism, so that $\bar{\delta}$ is of degree 5 and satisfies $\bar{\delta}\left(x i^{*}(y)\right)=\bar{\delta}(x) y$.

Proof. The Thom isomorphism is given by multiplication by $\tau_{6 W+4}$. So any element of $\widetilde{K O_{\Gamma}^{*}}\left(\Sigma^{7 V} \wedge E_{6+}\right)$ may be written as $x=\tau_{6 W+4} \wedge x^{\prime}$ for some $x^{\prime}$ $\in \widetilde{K O}_{\Gamma}^{*}\left(\Sigma^{V+4} \wedge E_{6+}\right)$. Now by (1.8) the restriction of $\tau_{6 W+4}$ to $\widetilde{K_{I}}\left(\Sigma^{4}\right)$ is $9 r\left(\mu^{2} V-\mu^{2}\right)$ and by Theorem $2.127 \sigma=0$. Therefore we see that $3 j^{*}(x)=0$.

Consider $c(x) \in \tilde{K}_{r}^{*}\left(\Sigma^{7 V} \wedge E_{6+}\right)$. Then $c(x)$ may be written in the form $c(x)=\tau_{7 V} \wedge y$ for some $y \in K_{I}^{*}\left(E_{6}\right)=K^{*}\left(P E_{6}\right)$. So the restriction of $c(x)$ to $K^{*}\left(P E_{6}\right)$ is $27 \sigma y$ which is, of course, zero. This shows that $c\left(j^{*}(x)\right)=0$, so that applying $r$ to this equality yields $2 j^{*}(x)=0$. By comparing these two results we see that $j^{*}=0$ whence the assertion follows.

We are in need of $K O_{T}^{*}\left(S(7 V) \times E_{6}\right)$, which is given inductively as in the complex case by changing 7 for $0,1, \cdots, 6$ in turn.

In order to describe the result we give some elements of $K O_{I}^{*}\left(S(n V) \times E_{6}\right)$ for $1 \leq n \leq 7$. Similarly to the complex case we write $\tilde{a}$ for $\pi_{1}^{*}(a)$ (resp. $\left.\pi_{2}^{*}(a)\right)$ where $a \in K O_{\Gamma}^{*}(S(n V))=K O^{*}\left(L^{n-1}(3)\right)$ (resp. $\left.a \in K O_{\Gamma}^{*}\left(E_{6}\right)=K O^{*}\left(P E_{6}\right)\right)$. Moreover, since $K O_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right)=K O^{*}\left(S(7 V) \times{ }_{I} E_{6}\right)$, by [12], Proposition 4.7 we have elements $\tilde{\lambda}_{1}, \tilde{\lambda}_{2} \in K O_{r}\left(S(7 V) \times E_{6}\right)$ such that $c\left(\tilde{\lambda}_{1}\right)=\mu^{3} \widetilde{\beta}\left(\rho_{1}\right) \widetilde{\beta}\left(\rho_{1}^{*}\right), c\left(\tilde{\lambda}_{2}\right)=\mu^{3} \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right)$, which satisfy $\tilde{\lambda}_{1}^{2}=\tilde{\lambda}_{2}^{2}=0$. For the restriction of these elements to $K O_{\Gamma}^{*}\left(S(n V) \times E_{6}\right)$ for
$1 \leq n \leq 6$ we use the same notation. We denote by $\tilde{F}$ the subalgebra of $K O_{I}^{*}\left(S(n V) \times E_{6}\right)$ generated by $\widetilde{\beta}(\rho), \widetilde{\beta}\left(\lambda^{3} \rho_{1}\right), \tilde{\lambda}_{1}, \tilde{\lambda}_{2}$ and by $\tilde{T}$ the submodule of $K_{I}^{*}\left(S(n V) \times E_{6}\right)$ generated by the monomials $\boldsymbol{n} \widetilde{\beta}\left(\rho_{1}\right), n \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right), n \widetilde{\beta}\left(\rho_{1}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right)$, $\boldsymbol{n} \widetilde{\beta}\left(\rho_{1}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right), \boldsymbol{n} \widetilde{\beta}\left(\rho_{1}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right), \boldsymbol{n} \beta\left(\rho_{1}\right) \widetilde{\beta}\left(\rho_{1}^{*}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right)$ where $\boldsymbol{n}$ is a monomial in $\widetilde{\beta}(\rho), \widetilde{\beta}\left(\lambda^{3} \rho_{1}\right)$.

Using the canonical action of $K O^{*}\left(L^{n}(3)\right)=K O_{\Gamma}^{*}\left(S((n+1) V)\right.$ on $K O_{T}^{*}(S((n$ $+1) V) \times E_{6}$ ) induced by the external product we obtain the following isomorphism.

Lemma 3.3. With the notation as above

$$
K O_{\Gamma}^{*}\left(S((n+1) V) \times E_{6}\right) \cong K O^{*}\left(L^{n}(3)\right) \otimes_{K O^{*}(+)} \tilde{F} \oplus r\left(K^{*}\left(L^{n}(3)\right) \otimes \tilde{T}\right)
$$

for $0 \leq n \leq 6$ as a $K O^{*}(+)$-module and $\tilde{F}$ is a free $K O^{*}(+)$-module.
Proof. The proof is quite similar to that of Lemma 2.2 and so proceeds inductively on $n$. Consider the exact sequence (1.3) when $X=E_{6}$

$$
\cdots \rightarrow K O^{*}\left(S^{1} \times E_{6}\right) \xrightarrow{J} K O_{\Gamma}^{*}\left(S((n+1) V) \times E_{6}\right) \xrightarrow{i^{*}} K O_{\Gamma}^{*}\left(S(n V) \times E_{6}\right) \xrightarrow{\bar{\delta}} \cdots
$$

provided with the equality $\bar{\delta}\left(x i^{*}(y)\right)=\bar{\delta}(x) y$. Viewing $S(V)$ as a $\Gamma$-invariant subspace of $E_{6}$ as in the proof of Lemma 2.2 yields $S(V) \times{ }_{r} E_{6} \approx S^{1} \times E_{6}$ so that $K O_{\Gamma}^{*}\left(S(V) \times E_{6}\right) \cong K O^{*}\left(S^{1}\right) \otimes_{K O^{*}(+)} K O^{*}\left(E_{6}\right)$. So we may write $K O_{\Gamma}^{*}\left(S(V) \times E_{6}\right)$ $=K O^{*}\left(E_{6}\right) \oplus K O^{*}\left(E_{6}\right) \cdot l_{0}$ where $t_{0}$ is the generator of $\widetilde{K O^{1}}\left(S^{1}\right)$ as in Section 1. Hence by (1.6) and the argument as in the proof of Lemma 2.2 we get Lemma 3.3 when $n=0$. This is, of course, the 1 st stage of our induction.

Next consider the maps of the above sequence. Then clearly $i^{*}(x)=x$ for $x \in \tilde{F}, x \in \tilde{T}$ and $i^{*}\left(\tilde{\bar{\sigma}}_{n, i}\right)=\tilde{\bar{\sigma}}_{n-1, i}$. By (1.10) we have $\delta\left(\tilde{\bar{v}}_{n-1}\right)=3, J\left(l_{0}\right)=\tilde{\bar{v}}_{n}$ and $J\left(r\left(\mu^{i+\eta}\right)\right)=r\left(\mu^{i}\left(-\tilde{\sigma}^{\eta}\right)\right)$. Moreover we note that the degree of $v_{n}$ is considered to be -1 , so that $c(\bar{v})=\mu^{3-n} v_{n}$. Using these formulas together with the equality $\bar{\delta}\left(x i^{*}(y)\right)=\bar{\delta}(x) y$, (1.6) and (1.11) (ii) we can go on with our induction. Thus we get the lemma.

We are now ready to prove the theorem.

## 4. Proof of Theorem 3.1

We continue to prove the theorem. We identify the isomorphism of Lemma 3.3 below and consider the images of the elements of $K O^{*}\left(P E_{6}\right)$ described in Theorem 3.1 by $i^{*}$ of Lemma 3.2. It is immediate by definition that $i^{*}\left(\bar{\sigma}_{i}\right)=\bar{\sigma}_{6, i}$, $i^{*}(\beta(\rho))=\widetilde{\beta}(\rho), i^{*}\left(\beta\left(\lambda^{3} \rho_{1}\right)\right)=\widetilde{\beta}\left(\lambda^{3} \rho_{1}\right)$. And by (2.4) $i^{*}\left(r\left(\mu^{i} \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)\right)=r\left(\mu^{i} \widetilde{\beta}\left(\rho_{1}\right)+(\sigma\right.$ $\left.+1) \mu^{i} \widetilde{\beta}\left(\rho_{1}^{*}\right)\right), i^{*}\left(r\left(\mu^{i} \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)\right)\right)=r\left(13 \mu^{i} \widetilde{\beta}\left(\rho_{1}\right)+(\sigma+1) \mu^{i} \widetilde{\beta}\left(\lambda^{2} \rho_{1}\right)\right), i^{*}\left(r\left(\mu^{i} \beta\left(\rho_{1}, \Gamma\right)\right)\right)=$ $r\left(\left(\sigma^{2}+3 \sigma+3\right) \mu^{i} \widetilde{\beta}\left(\rho_{1}\right)-\mu^{i} v_{6}\right)$. Furthermore we may assume that

$$
\begin{equation*}
i^{*}(\lambda)=13^{2} \tilde{\lambda}_{1}+\tilde{\lambda}_{2}+13 r\left(\left(\sigma_{6}+1\right)^{2} \mu^{3} \tilde{\beta}\left(\rho_{1}\right) \tilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right)\right) . \tag{4.1}
\end{equation*}
$$

Because, by using the Bott exact sequence we see that the difference between the elements on the both sides can be written as the form $\eta_{1} a$ where $a \in K O_{\Gamma}^{-7}\left(S(7 V) \times E_{6}\right)$ which satisfies $a^{2}=0$ by [4], Example (6.6) and hence if necessary it suffices to replace either $\tilde{\lambda}_{1}$ or $\tilde{\lambda}_{2}$ by $\tilde{\lambda}_{1}+\eta_{1} a$ or $\tilde{\lambda}_{2}+\eta_{1} a$. (In fact these $a$ 's above must be zero by the same reason as mentioned in Remark 2 for (1.6).) Similarly by definition we can write as $i^{*}\left(\bar{\lambda}_{1}\right)=\left(\bar{\sigma}_{6,0}+3\right) \tilde{\lambda}_{1}-\bar{v}_{6} r\left(\mu^{2} \widetilde{\beta}\left(\rho_{1}\right)\right)+\eta_{1} a$ for some $a \in K O_{r}^{-7}\left(S(7 V) \times E_{6}\right)$. But the odd dimensional generators of the first direct summand of $K O_{I}^{*}\left(S(7 V) \times E_{6}\right)$ in Lemma 3.3 is only $\widetilde{\beta}(\rho), \widetilde{\beta}\left(\lambda^{3} \rho_{1}\right), \bar{v}_{6}$ and so we see that the component of $a$ which belongs to this direct summand is divisible by $\eta_{1}^{2}$. Therefore $\eta_{1} a$ must be zero since $\eta_{1} r(x)=0$, so that we have

$$
\begin{equation*}
i^{*}\left(\bar{\lambda}_{1}\right)=\left(\bar{\sigma}_{6,0}+3\right) \tilde{\lambda}_{1}-\bar{v}_{6} r\left(\mu^{2} \widetilde{\beta}\left(\rho_{1}\right)\right) . \tag{4.2}
\end{equation*}
$$

Since $i^{*}$ is injective by Lemma 3.2, it follows from this and the relation of (1.11) (ii) that $\bar{\sigma}_{i} \bar{\lambda}_{1}=0$.

Because of the injectivity of $i^{*}$ of (2.3), we get by (2.4)

$$
\begin{aligned}
& \beta\left(\rho_{1}, \Gamma\right)+\beta\left(\rho_{1}, \Gamma\right)^{*}=\left(\sigma^{2}+3 \sigma+3\right) \beta\left(\rho_{1}+\rho_{1}^{*}\right), \beta\left(\rho_{1}+\rho_{1}^{*}\right)^{*} \\
& \quad=(\sigma+1)^{2} \beta\left(\rho_{1}+\rho_{1}^{*}\right), \beta\left(\lambda^{2} \rho_{1}+\lambda^{2} \rho_{1}^{*}\right)=(\sigma+1)^{2}\left(\beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)\right. \\
& \left.\quad-13 \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)+\beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right) .
\end{aligned}
$$

(The last element can be defined analogously to $\beta\left(\rho_{1}+\rho_{1}^{*}\right)$.)
Denote by $R$ the algebra over $K O^{*}(+)$ on the right-hand side of the equality of Theorem 3.1. In virtue of the formulas above and (1.11), Lemmas 3.2, 3.3 and Theorem 2.1 we can then verify that $R$ is a subalgebra of $K O *\left(P E_{6}\right)$. From now on we prove that $K O^{*}\left(P E_{6}\right)$ is filled with $R$. This is sufficient to show Theorem 3.1.

Observe the following exact sequence of (1.2) (i)

$$
\cdots \rightarrow \widetilde{K O}_{\Gamma}^{*}\left(\Sigma^{V} \wedge E_{6+}\right) \xrightarrow{j_{1}^{*}} K O^{*}\left(P E_{6}\right) \xrightarrow{i_{1}} K O_{\Gamma}^{*}\left(S(V) \times E_{6}\right) \xrightarrow{\delta_{1}} \cdots
$$

When we regard $S(V)$ as the circle group which is a factor of $\operatorname{Spin}(10) \cdot S^{1} \subset E_{6}$ as before we have $S(V) \times{ }_{\Gamma} E_{6} \approx S^{1} \times E_{6}$, so that $K O_{\Gamma}^{*}\left(S(V) \times E_{6}\right) \cong K O^{*}\left(S^{1} \times E_{6}\right)$, and so this sequence can be written as

$$
\begin{equation*}
\cdots \rightarrow \widetilde{K O}_{\Gamma}^{*}\left(\Sigma^{V} \wedge E_{6+}\right) \xrightarrow{j_{1}^{1}} K O^{*}\left(P E_{6} \xrightarrow{i_{1}^{i_{1}}} K O^{*}\left(S^{1} \times E_{6}\right) \xrightarrow{\delta_{1}} \cdots\right. \tag{4.3}
\end{equation*}
$$

Moreover we can write as

$$
K O^{*}\left(S^{1} \times E_{6}\right)=K O^{*}\left(E_{6}\right) \oplus K O^{*}\left(E_{6}\right) \cdot \iota_{0}
$$

where $t_{0}$ denotes the generator of $K O^{-7}\left(S^{1}\right) \cong Z$.
To investigate $\operatorname{Im} i_{1}^{*}$ under the identification above we consider $i_{2}^{*}: h_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right)$
$\rightarrow h_{\Gamma}^{*}\left(S(V) \times E_{6}\right)$ for $h=K O, K$ where $i_{2}$ denotes an inclusion of $S(V) \times E_{6}$ into $S(7 V) \times E_{6}$. From the arguments as in the proofs of Lemmas 2.2 and 3.3 it follows that $i_{2}^{*}(\tilde{\beta}(a))=\beta(a)$ for the fundamental representations $a$ 's of $E_{6}$ so that $i_{2}^{*}\left(\tilde{\lambda_{k}}\right)=\lambda_{k}$ $(k=1,2)$, and $i_{2}^{*}\left(\sigma_{6}\right)=i_{2}^{*}\left(v_{6}\right)=0$ so that $i_{2}^{*}\left(\bar{\sigma}_{6, i}\right)=i_{2}^{*}\left(\bar{v}_{6}\right)=0$. Therefore we have $i_{2}^{*}\left(\widetilde{\beta}\left(\rho_{1}\right)\right)=\beta\left(\rho_{1}\right)$. For the same reasons we get $i_{2}^{*}\left(\widetilde{\beta}\left(\lambda^{2} \rho_{1}\right)\right)=\beta\left(\lambda^{2} \rho_{1}\right)$. As to the other generators of $K O_{I}^{*}\left(S(7 V) \times E_{6}\right)$ it follows immediately by definition that $i_{2}^{*}\left(\sigma_{6}\right)=i_{2}^{*}\left(v_{6}\right)=0, i_{2}^{*}\left(\bar{\sigma}_{6, i}\right)=i_{2}^{*}\left(\bar{v}_{6}\right)=0$. These formulas, Lemma 3.3 and (1.6) show that

$$
i_{2}^{*}\left(K O_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right)\right)=K O^{*}\left(E_{6}\right)
$$

and so because of $i_{1}^{*}=i_{2}^{*} i^{*}$ where $i^{*}$ is as in Lemma 3.2 we have

$$
i_{1}^{*}\left(K O^{*}\left(P E_{6}\right)\right) \subset K O^{*}\left(E_{6}\right)
$$

in (4.3). More precisely we have

## Lemma 4.4. <br> $$
i_{1}^{*}\left(K O^{*}\left(P E_{6}\right)\right)=i_{1}^{*}(R)
$$

Proof. We use the same notation as in (4.3) below for the maps $j_{1}^{*}, i_{1}^{*}, \delta_{1}$ of the same kind in the complex version of (4.3). Then by (2.4) we get
(4.5) $\quad i_{1}^{*}\left(\beta\left(\rho_{1}, \Gamma\right)\right)=3 \beta\left(\rho_{1}\right), i_{1}^{*}\left(\beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)=\beta\left(\rho_{1}\right)+\beta\left(\rho_{1}^{*}\right) \quad$ and $\quad i_{1}^{*}\left(\beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)\right)$

$$
=13 \beta\left(\rho_{1}\right)+\beta\left(\lambda^{2} \rho_{1}\right) .
$$

For any $x \in \widetilde{K_{O}}{ }^{*}\left(P E_{6}\right)$ we see by Theorem 2.1 that $c(x)$ can be written as a polynomial in

$$
\sigma, \beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right), \beta\left(\rho_{1}+\rho_{1}^{*}\right), \beta\left(13 \rho+\lambda^{2} \rho_{1}\right), \beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right), \beta\left(\rho_{1}, \Gamma\right)
$$

with coefficients in $Z[\mu] /\left(\mu^{4}-1\right)$. Therefore using (4.5) it follows that $i_{1}^{*}(c(x))$ is written as a polynomial in

$$
\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right), \beta\left(\rho_{1}\right)+\beta\left(\rho_{1}^{*}\right), \beta\left(\rho_{1}\right)+\beta\left(\lambda^{2} \rho_{1}\right), \beta\left(\rho_{\mathrm{i}}^{*}\right)+\beta\left(\lambda^{2} \rho_{1}^{*}\right), 3 \beta\left(\rho_{1}\right)
$$

with coefficients in $Z[\mu] /\left(\mu^{4}-1\right)$.
On the other hand it follows from (1.5), (1.6) that $c\left(i_{1}^{*}(x)\right)$ can be written as a sum of a polynomial in
$\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right), \mu^{3} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right), \mu^{3} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)$,

$$
2 \mu^{2} \beta(\rho), 2 \mu^{2} \beta\left(\lambda^{3} \rho_{1}\right), 2 \mu \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right), 2 \mu \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)
$$

and the elements in the form

$$
\boldsymbol{n} \mu^{i}\left(\beta\left(\rho_{1}\right)+(-1)^{i} \beta\left(\rho_{1}^{*}\right)\right), \boldsymbol{n} \mu^{i}\left(\beta\left(\lambda^{2} \rho_{1}\right)+(-1)^{i} \beta\left(\lambda^{2} \rho_{1}^{*}\right)\right), ~, ~ \mu^{i}\left(\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)+(-1)^{i} \beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right),
$$

$$
\boldsymbol{n} \mu^{i} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)\left(\beta\left(\rho_{1}\right)+(-1)^{i+1} \beta\left(\rho_{1}^{*}\right)\right), \boldsymbol{n} \mu^{i} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right)\left(\beta\left(\lambda^{2} \rho_{1}\right)+(-1)^{i+1} \beta\left(\lambda^{2} \rho_{1}^{*}\right)\right)
$$

where $\boldsymbol{n}$ is a monomial in $\beta(\rho), \beta\left(\lambda^{3} \rho_{1}\right)$ with coefficients in $\boldsymbol{Z}$. By combining these two facts we see that $i_{1}^{*}(c(x))$ must be written as a sum of a polynomial in

$$
\beta(\rho), \beta\left(\lambda^{3} \rho\right), 2 \mu^{2} \beta(\rho), 2 \mu^{2} \beta\left(\lambda^{3} \rho_{1}\right), 3 \mu^{3} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right), 3 \mu^{3} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right),
$$ $3 \mu^{2} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right), 6 \mu \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right), 6 \mu \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)$, $6 \mu \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right), \mu^{3}\left(\beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right)+\beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)+\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)\right.$ $\left.-\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right)$,

$$
2 \mu\left(\beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right)+\beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)+\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)-\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right)
$$

and the elements in the form

$$
\begin{gathered}
\boldsymbol{n} \mu^{2 i}\left(\beta\left(\rho_{1}\right)+\beta\left(\rho_{1}^{*}\right)\right), \boldsymbol{n} \mu^{2 i}\left(\beta\left(\lambda^{2} \rho_{1}\right)+\beta\left(\lambda^{2} \rho_{1}^{*}\right)\right), 3 \boldsymbol{n} \mu^{2 i+1}\left(\beta\left(\rho_{1}\right)-\beta\left(\rho_{1}^{*}\right)\right), \\
3 \boldsymbol{n} \mu^{2 i+1}\left(\beta\left(\lambda^{2} \rho_{1}\right)-\beta\left(\lambda^{2} \rho_{1}^{*}\right)\right), 9 \boldsymbol{n} \mu^{2 i}\left(\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)+\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right), \\
3 \boldsymbol{n} \mu^{3}\left(\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)-\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right), 6 \boldsymbol{n} \mu\left(\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)-\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right), \\
3 \boldsymbol{n} \mu^{2 i+1} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)\left(\beta\left(\rho_{1}\right)+\beta\left(\rho_{1}^{*}\right)\right), 9 \boldsymbol{n} \mu^{2 i} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)\left(\beta\left(\rho_{1}\right)-\beta\left(\rho_{1}^{*}\right)\right), \\
3 \boldsymbol{n} \mu^{2 i+1} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right)\left(\beta\left(\lambda^{2} \rho_{1}\right)+\beta\left(\lambda^{2} \rho_{1}^{*}\right)\right), 9 \boldsymbol{n} \mu^{2 i} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right)\left(\beta\left(\lambda^{2} \rho_{1}\right)-\beta\left(\lambda^{2} \rho_{1}^{*}\right)\right)
\end{gathered}
$$

where $\boldsymbol{n}$ is as above.
From (4.1), (4.2) and (4.5) we get

$$
\begin{gathered}
c i_{1}^{*}(\beta(\rho))=\beta(\rho), c i_{1}^{*}\left(\eta_{4} \beta(\rho)\right)=2 \mu^{2} \beta(\rho), c i_{1}^{*}\left(\beta\left(\lambda^{3} \rho_{1}\right)\right)=\beta\left(\lambda^{3} \rho_{1}\right), \\
c i_{1}^{*}\left(\eta_{4} \beta\left(\lambda^{3} \rho_{1}\right)\right)=2 \mu^{2} \beta\left(\lambda^{3} \rho_{1}\right), c i_{1}^{*}\left(\lambda_{1}\right)=3 \mu^{3} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right), \\
c i_{1}^{*}\left(\eta_{4} \bar{\lambda}_{1}\right)=6 \mu \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right), c i_{1}^{*}\left(r\left(\mu^{i} \beta\left(\rho_{1}, \Gamma\right)\right)\right)=3 \mu^{i}\left(\beta\left(\rho_{1}\right)+(-1)^{i} \beta\left(\rho_{1}^{*}\right)\right), \\
c i_{1}^{*}\left(r\left(\mu^{2 i}\left(\beta\left(\rho_{1}, \Gamma\right)-\beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)\right)=\mu^{2 i}\left(\beta\left(\rho_{1}\right)+\beta\left(\rho_{1}^{*}\right)\right),\right. \\
c i_{1}^{*}\left(r\left(\mu^{i}\left(3 \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)-13 \beta\left(\rho_{1}, \Gamma\right)\right)\right)\right)=3 \mu^{i}\left(\beta\left(\lambda^{2} \rho_{1}\right)+(-1)^{i} \beta\left(\lambda^{2} \rho_{1}^{*}\right)\right), \\
c i_{1}^{*}\left(r\left(\mu^{2 i}\left(\beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)-13 \beta\left(\rho_{1}, \Gamma\right)+13 \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)\right)\right)=\mu^{2 i}\left(\beta\left(\lambda^{2} \rho_{1}\right)+\beta\left(\lambda^{2} \rho_{1}^{*}\right)\right)
\end{gathered}
$$

and furthermore setting

$$
\begin{gathered}
a=r\left(\mu^{3} \beta\left(\rho_{1}, \Gamma\right) \beta\left(13 \rho_{1}+\rho_{1}^{*}\right)\right)-13 \bar{\lambda}_{1}, b=3 \lambda-299 \bar{\lambda}_{1}-13 a, c=\lambda-121 \bar{\lambda}_{1}-4 a \\
d=r\left(\mu^{2 i}\left(3 \beta\left(\rho_{1}+\rho_{1}^{*}\right)-13 \beta\left(\rho_{1}, \Gamma\right)\right)\left(3 \beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)-13 \beta\left(\rho_{1}, \Gamma\right)\right)\right)
\end{gathered}
$$

we get

$$
c i_{1}^{*}(\mathrm{a})=3 \mu^{3}\left(\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)-\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right), c i_{1}^{*}(b)=3 \mu^{3} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right),
$$

$$
\begin{gathered}
c i_{1}^{*}(c)=\mu^{3}\left(\beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right)+\beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)+\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)-\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right), \\
c i_{1}^{*}\left(a r\left(\mu^{2 i}\left(\beta\left(\rho_{1}, \Gamma\right)-\beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)\right)=3 \mu^{2 i+3} \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)\left(\beta\left(\rho_{1}\right)+\beta\left(\rho_{1}^{*}\right)\right),\right. \\
c i_{1}^{*}(a c)=3 \mu^{2} \beta\left(\rho_{1}\right) \beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right), c i_{1}^{*}(d)=9 \mu^{2 i}\left(\beta\left(\rho_{1}\right) \beta\left(\lambda^{2} \rho_{1}^{*}\right)+\beta\left(\rho_{1}^{*}\right) \beta\left(\lambda^{2} \rho_{1}\right)\right) .
\end{gathered}
$$

By comparing these formulas with the above we obtain
(4.6) For any $x \in K O^{*}\left(P E_{6}\right)$ there exists an element $y \in R$ such that $c i_{1}^{*}(x)=c i_{1}^{*}(y)$.

By (4.6) and (1.6) we have $i_{1}^{*}(x-y) \in F \cdot \eta_{1}$ using the symbols of (4.6) where $F$ is as in (1.6). But $\eta_{1} \lambda_{1}=i_{1}^{*}\left(\eta_{1} \bar{\lambda}_{1}\right), \eta_{1} \lambda_{2}=i_{1}^{*}\left(\eta_{1} \lambda+\eta_{1} \bar{\lambda}_{1}\right)$ by (4.1), (4.2) and clearly $i_{1}^{*}(\beta(\rho))=\beta(\rho), i_{1}^{*}\left(\beta\left(\lambda^{3} \rho_{1}\right)\right)=\beta\left(\lambda^{3} \rho_{1}\right)$. So we see that for any $x \in K O^{*}\left(P E_{6}\right)$ there exist elements $y, z \in R$ such that $i_{1}^{*}(x)=i_{2}^{*}\left(y+\eta_{1} z\right)$. This completes the proof of Lemma 4.4.

Finally we consider the image of of $j_{1}^{*}$ of (4.3). Then we have
Lemma 4.7.

$$
j_{1}^{*}\left(\widetilde{K O}_{\Gamma}^{*}\left(\Sigma^{V} \wedge E_{6+}\right)\right) \subset R .
$$

Proof. Consider the composition of $j_{1}^{*}$ with $\bar{\delta}$ of Lemma 3.2. Then $\operatorname{Im} j_{1}^{*} \delta=\operatorname{Im} j_{1}^{*}$ because of the surjectivity of $\bar{\delta}$. So it suffices to check that

$$
j_{1}^{*} \bar{\delta}\left(K O_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right)\right) \subset R .
$$

According to Lemma 3.3, $K O_{\Gamma}^{*}\left(S(7 V) \times E_{6}\right)=K O^{*}\left(L^{6}(3)\right) \otimes_{K O^{*}(+)} \tilde{F} \oplus r\left(K^{*}\left(L^{6}(3)\right) \otimes \tilde{T}\right)$. First we consider the image of the latter direct summand. Observe $\bar{\delta}\left(K^{*}\left(L^{6}(3)\right) \otimes \tilde{T}\right)$ where $\delta$ is the coboundary homomorphism of the same kind in the complex case. From (2.4) and the equalities $c\left(\tau_{6 W+4}\right)=\tau_{6 V} \mu^{2}, \tau_{7 V}=\tau_{6 V} \wedge \tau_{V}$ it follows that $\delta\left(\tilde{\beta}\left(\rho_{1}\right)\right)=-\tau_{V} \mu^{2}, \bar{\delta}\left(v_{6}\right)=\left(\sigma^{2}+3 \sigma+3\right) \tau_{V} \mu^{2}$. Together with this, using the formulas in the preceding of (2.4) and the equality $\bar{\delta}\left(x i^{*}(y)\right)=\bar{\delta}(x) y$ where $i^{*}$ is as in (2.3) we can get $\bar{\delta}\left(K^{*}\left(L^{6}(3)\right) \otimes \tilde{T}\right)$ and so it can be easily verified that $j_{1}^{*} \bar{\delta}\left(r\left(K^{*}\left(L^{6}(3)\right) \otimes \tilde{T}\right)\right)$ $\subset R$ by using $c\left(\tau_{6 W+4}\right)=\tau_{6 V} \mu^{2}$.

We now observe the image of another direct summand. Clearly $j_{1}^{*} \bar{\delta}(x)=0$ for $x=\bar{\sigma}_{6, i}, \widetilde{\beta}(\rho)$ and $\widetilde{\beta}\left(\lambda^{3} \rho_{1}\right)$. As to the image of $\bar{v}_{6} \in K O^{-3}\left(L^{6}(3)\right)=K O_{r}^{-3}(S(7 V))$ by $j_{1}^{*} \bar{\delta}$ we see by definition that $j_{1}^{*} \delta\left(\bar{v}_{6}\right) \in K O_{\Gamma}^{-6}(+)=Z \cdot W \mu^{3}$ and $c j_{1}^{*} \delta\left(\bar{v}_{6}\right)=0$ using $c\left(\bar{v}_{6}\right)=\mu v_{6}$. But $c\left(W \mu^{3}\right) \neq 0$, which shows that

$$
j_{1}^{*} \bar{\delta}\left(\bar{v}_{6}\right)=0 .
$$

By definiton we can write as $c\left(\tilde{\lambda}_{1}\right)=-i^{*}\left(\mu(\sigma+1)^{2} \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right) \widetilde{\beta}\left(\rho_{1}\right)$ where $i^{*}$ is as in (2.3). Therefore $c j_{1}^{*} \delta\left(\tilde{\lambda_{1}}\right)=-\left(\sigma^{2}+2 \sigma\right) \mu \beta\left(\rho_{1}+\rho_{1}^{*}\right)$, so that $c j_{1}^{*} \delta\left(\tilde{\lambda}_{1}\right)=\operatorname{cr}\left(\mu \beta\left(\rho_{1}\right.\right.$ $\left.+\rho_{1}^{*}\right)$ ). Now $i_{1}^{*} r\left(\mu \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)=0$. So we can construct an element $a_{1} \in \widetilde{K O_{\Gamma}^{-3}}\left(\Sigma^{V}\right.$ $\left.\wedge E_{6+}\right)$ such that $j_{1}^{*}\left(a_{1}\right)=r\left(\mu \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)$ and $c\left(a_{1}\right)=-\tau_{V}(\sigma+1)^{2} \mu \beta\left(\rho_{1}+\rho_{1}^{*}\right)$. Then, from the surjectivity of $\bar{\delta}$ and the uniqueness of $\tilde{\lambda}_{1}$ it follows that $\bar{\delta}\left(\tilde{\lambda}_{1}\right)=a_{1}$, so that

$$
j_{1}^{*} \bar{\delta}\left(\tilde{\lambda_{1}}\right)=r\left(\mu \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right) .
$$

Similarly we obtain

$$
j_{1}^{*} \bar{\delta}\left(\tilde{\lambda}_{2}\right)=r\left(\mu(\sigma+1)^{2}\left(\beta\left(13 \rho_{1}+\lambda^{2} \rho_{1}\right)-13 \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)+\mu \beta\left(13 \rho_{1}^{*}+\lambda^{2} \rho_{1}^{*}\right)\right) .
$$

Using these three formulas we can easily prove that $j_{\tilde{\tilde{D}}}^{*} \bar{\delta}\left(K O^{*}\left(L^{6}(3)\right) \otimes_{K o^{*}(+)} \tilde{F}\right)$ $\subset R$. For example, since $\tilde{\lambda}_{1} r\left(\left(\sigma_{6}+1\right) \mu^{3} \widetilde{\beta}\left(\rho_{1}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right)\right)=r\left(c\left(\tilde{\lambda}_{1}\right)\left(\sigma_{6}+1\right) \mu^{3} \widetilde{\beta}\left(\rho_{1}\right) \widetilde{\beta}\left(\lambda^{2} \rho_{1}^{*}\right)\right)$ $=0$, we have $\tilde{\lambda}_{1} i^{*}(\lambda)=\tilde{\lambda}_{1} \tilde{\lambda}_{2}$ by (4.1). Hence $j_{1}^{*} \bar{\delta}\left(\tilde{\lambda}_{1} \tilde{\lambda}_{2}\right)=\operatorname{\lambda r}\left(\mu \beta\left(\rho_{1}+\rho_{1}^{*}\right)\right)$. Thus the proof is completed.

From Lemmas 4.4, 4.7 and the exactness of (4.3) it follows that $K O^{*}\left(P E_{6}\right)=R$ immediately. This completes the proof of Theorem 3.1.
