# QUANTUM DEFORMATIONS OF CERTAIN PREHOMOGENEOUS VECTOR SPACES. II 

Yoshiyuki MORITA

(Received March 5, 1998)

## Introduction

Let $G$ be a reductive algebraic group over the complex number field $\mathbb{C}$ and let $\mathfrak{g}$ be its Lie algebra. The quantized coordinate algebra $A_{q}(G)$ of $G$ is constructed as a certain dual Hopf algebra of the quantized enveloping algebra $U_{q}(\mathfrak{g})$ of $\mathfrak{g}$. The Hopf algebras $U_{q}(\mathfrak{g})$ and $A_{q}(G)$ over $\mathbb{C}(q)$ tend to the ordinary enveloping algebra $U(\mathfrak{g})$ and the coordinate algebra $A(G)$ respectively when the parameter $q$ tends to 1 in a certain sense (Drinfeld [1], Jimbo [3]).

Let us consider what object we should regard as a quantum deformation of an affine variety $X$ with $G$-action.

An affine variety $X$ is endowed with an action of $G$ if and only if its coordinate algebra $A(X)$ is equipped with a right $A(G)$-comodule structure

$$
\tau: A(X) \rightarrow A(X) \otimes A(G)
$$

which is simultaneously an algebra homomorphism. By the duality between $U(\mathfrak{g})$ and $A(G)$ we obtain a locally finite left $U(\mathfrak{g})$-module structure

$$
\begin{equation*}
\gamma: U(\mathfrak{g}) \otimes A(X) \rightarrow A(X) \tag{*}
\end{equation*}
$$

given by

$$
\begin{equation*}
\tau(n)=\sum_{i} n_{i} \otimes f_{i} \Rightarrow \gamma(u \otimes n)=\sum_{i}\left\langle u, f_{i}\right\rangle n_{i}, \tag{**}
\end{equation*}
$$

where $\langle\rangle:, U(\mathfrak{g}) \times A(G) \rightarrow \mathbb{C}$ is the dual pairing. Since $\tau$ is an algebra homomorphism, we have

$$
(* * *) \quad u \in U(\mathfrak{g}), m, n \in A(X), \Delta(u)=\sum_{i} u_{i} \otimes v_{i} \Rightarrow u(m n)=\sum_{i}\left(u_{i} m\right)\left(v_{i} n\right),
$$

where $\Delta: U(\mathfrak{g}) \rightarrow U(\mathfrak{g}) \otimes U(\mathfrak{g})$ is the coproduct. Then the action of $G$ on $X$ is uniquely determined by the infinitesimal action $\gamma$. Moreover, for a locally finite left
$U(\mathfrak{g})$-module structure $(*)$ on $A(X)$ satisfying $(* * *)$ and a certain condition on irreducible $U(\mathfrak{g})$-modules appearing as submodules of $A(X)$, there exists a unique action of $G$ on $X$ whose infinitesimal action is given by $\gamma$.

Now we define the notion of a quantum deformation of an affine variety $X$ with $G$-action as follows. A (not necessarily commutative) $\mathbb{C}(q)$-algebra $A_{q}(X)$ endowed with a locally finite left $U_{q}(\mathfrak{g})$-module structure

$$
\gamma_{q}: U_{q}(\mathfrak{g}) \otimes A_{q}(X) \rightarrow A_{q}(X)
$$

is called a quantum deformation of $X$ if $A_{q}(X)$ and $\gamma_{q}$ tend to $A(X)$ and $\gamma: U(\mathfrak{g}) \otimes$ $A(X) \rightarrow A(X)$ respectively when $q$ tends to 1 and if it satisfies

$$
u \in U_{q}(\mathfrak{g}), \quad m, n \in A_{q}(X), \quad \Delta(u)=\sum_{i} u_{i} \otimes v_{i} \Rightarrow u(m n)=\sum_{i}\left(u_{i} m\right)\left(v_{i} n\right) .
$$

It seems to be an interesting problem to determine in which case $X$ admits a quantum deformation. In this paper we consider the problem when $X$ is a prehomogeneous vector space, that is, when $X$ is a vector space with a linear $G$-action containing an open $G$-orbit. Such a quantum deformation was intensively studied in the case where $G=G L_{m}(\mathbb{C}) \times G L_{n}(\mathbb{C})$ and $X=M_{m n}(\mathbb{C})$ (see Taft-Towber [10], Hashimoto-Hayashi [2] and Noumi-Yamada-Mimachi [7]), and also in the case where $G=G L_{n}(\mathbb{C})$ and $X$ is the set of skew symmetric matrices of degree $n$ (see Strickland [8]).

In our previous paper [4] we gave a general method to construct quantum deformations of prehomogeneous vector spaces of parabolic type. Moreover, for each nonopen $G$-orbit $C$ on $X$, we have shown that the defining ideal of the closure $\bar{C}$ and its canonical generators admit quantum deformations inside $A_{q}(X)$. It includes the existence of the quantum deformation of the irreducible relative invariant when $X$ is a regular prehomogeneous vector space. Indeed, the canonical generator of the defining ideal of the closure of the one-codimensional orbit is nothing but the irreducible relative invariant.

Quantum deformations of prehomogeneous vector spaces of commutative parabolic type associated to classical simple Lie algebras are intensively studied in Kamita [5]. In this paper we shall deal with the remaining two cases
(I) $\quad G=\mathbb{C}^{\times} \times \operatorname{Spin}(10, \mathbb{C}), X=\mathbb{C}^{16}$, the scalar multiplication and the half-spin representation,
(II) $G=\mathbb{C}^{\times} \times E_{6}, X=\mathbb{C}^{27}$, the scalar multiplication and the 27-dimensional irreducible representation of $E_{6}$,
which naturally arise from the exceptional simple Lie algebras of type $E_{6}$ and $E_{7}$ respectively using the method in our previous paper [4]. In Introduction we shall only state the results in case (II).

Let $\mathfrak{g}_{E_{7}}$ be a simple Lie algebra of type $E_{7}$ over $\mathbb{C}$ and let $\mathfrak{h}$ be its Cartan subalgebra. We shall use the labelling of the vertices of the Dynkin diagram 1.

Set $I_{0}=\{1,2, \ldots, 7\}, I=I_{0} \backslash\{1\}$. Let $\Delta \subset \mathfrak{h}^{*}$ be the root system of type $E_{7}$. We denote the set of simple roots by $\left\{\alpha_{i}\right\}_{i \in I_{0}}$ and the set of positive roots by $\Delta^{+}$. Let $():, \mathfrak{h}^{*} \times \mathfrak{h}^{*} \rightarrow \mathbb{C}$ be a standard symmetric bilinear form. Set $D=\Delta^{+} \backslash \sum_{i \in I} \mathbb{Z} \alpha_{i}$. Then we have $\sharp D=27$. Set $\Lambda=\{1,2, \ldots, 27\}$, and fix a bijection $\Lambda \ni j \mapsto \beta_{j} \in D$ such that $\beta_{k}-\beta_{j} \in \sum_{i \in I_{0}} \mathbb{Z}_{\geq 0} \alpha_{i}$ implies $j \leq k$, where $\mathbb{Z}_{\geq 0}=\{n \in \mathbb{Z} \mid n \geq 0\}$. Set $\delta=3 \alpha_{1}+4 \alpha_{2}+5 \alpha_{3}+6 \alpha_{4}+3 \alpha_{5}+4 \alpha_{6}+2 \alpha_{7}$. For each $n \in \Lambda$ there exist exactly five pairs $(i, j) \in \Lambda^{2}$ such that $\beta_{i}+\beta_{j}=\delta-\beta_{n}, i<j$. We denote them by $\left(i_{1}^{n}, j_{1}^{n}\right),\left(i_{2}^{n}, j_{2}^{n}\right),\left(i_{3}^{n}, j_{3}^{n}\right),\left(i_{4}^{n}, j_{4}^{n}\right),\left(i_{5}^{n}, j_{5}^{n}\right) \in \Lambda^{2}$ where $i_{5}^{n}<i_{4}^{n}<i_{3}^{n}<i_{2}^{n}<i_{1}^{n}$. Let $K_{i}^{ \pm 1}, E_{i}, F_{i}\left(i \in I_{0}\right)$ be the canonical generators of $U_{q}\left(g_{E_{7}}\right)$, and set $U_{q}(\mathfrak{g})=$ $\left\langle K_{1}^{ \pm 3}, K_{j}^{ \pm 1}, E_{j}, F_{j} \mid j \in I\right\rangle \subset U_{q}\left(g_{E_{7}}\right)$. Then $U_{q}(\mathfrak{g})$ is isomorphic to the tensor product of $\mathbb{C}(q)\left[K, K^{-1}\right]$ and the quantized enveloping algebra of type $E_{6}$, where $K=K_{1}^{3} K_{2}^{4} K_{3}^{5} K_{4}^{6} K_{5}^{3} K_{6}^{4} K_{7}^{2}$.

Theorem 0.1. A quantum deformation of the 27-dimensional irreducible prehomogeneous vector space $X$ of $G=\mathbb{C}^{\times} \times E_{6}$ is given by the following.
(a) $\quad A_{q}(X)$ is an associative $\mathbb{C}(q)$-algebra defined by the following generators and fundamental relations:
Generators: $Y_{i}$ with $i=1, \ldots, 27$.
Fundamental relations: For $i<j$
$Y_{i} Y_{j}=\left\{\begin{array}{l}q Y_{j} Y_{i} \quad \text { if } \beta_{i}+\beta_{j} \text { does not have another decomposition } \beta+\beta^{\prime}, \beta, \beta^{\prime} \in D, \\ Y_{j} Y_{i}+q Y_{b} Y_{a}-q^{-1} Y_{a} Y_{b} \\ \quad \text { if there exist } k \in I, a, b \in \Lambda \text { such that } \beta_{a}=\beta_{i}+\alpha_{k}, \beta_{b}=\beta_{j}-\alpha_{k}, \\ Y_{j} Y_{i} \quad \text { otherwise. }\end{array}\right.$
(b) The action $\gamma_{q}: U_{q}(\mathfrak{g}) \otimes A_{q}(X) \rightarrow A_{q}(X)$ is given by the following.

For $2 \leq k \leq 7,1 \leq m \leq 7$

$$
\begin{aligned}
& \gamma_{q}\left(F_{k} \otimes Y_{i}\right)= \begin{cases}Y_{j} \text { if there exists } j \text { such that } \beta_{j}=\beta_{i}+\alpha_{k}, \\
0 & \text { otherwise, }\end{cases} \\
& \gamma_{q}\left(E_{k} \otimes Y_{i}\right)= \begin{cases}Y_{j} & \text { if there exists } j \text { such that } \beta_{j}=\beta_{i}-\alpha_{k}, \\
0 & \text { otherwise, }\end{cases} \\
& \gamma_{q}\left(K_{m} \otimes Y_{i}\right)=q^{-\left(\alpha_{m}, \beta_{i}\right)} Y_{i} .
\end{aligned}
$$

(c) The quantum deformation of the irreducible relative invariant of $X$ is given by

$$
\varphi=\sum_{n \in \Lambda}(-q)^{\left|\beta_{n}\right|-1} Y_{n} \psi_{n}
$$

where $|\beta|=\sum_{i \in I_{0}} m_{i}\left(\beta=\sum_{i \in I_{0}} m_{i} \alpha_{i}\right), \psi_{n}=Y_{i_{5}^{n}} Y_{j_{5}^{n}}-q Y_{i_{4}^{n}} Y_{j_{4}^{n}}+q^{2} Y_{i_{3}^{n}} Y_{j_{3}^{n}}-$ $q^{3} Y_{i_{2}^{n}} Y_{j_{2}^{n}}+q^{4} Y_{i_{1}^{n}} Y_{i_{1}^{n}}$.

The author expresses gratitude to Professor Noriaki Kawanaka and Professor Toshiyuki Tanisaki.

## 1. Preliminaries

Let $\mathfrak{g}$ be a simple Lie algebra of type $E_{6}$ or $E_{7}$ over the complex number field $\mathbb{C}$, and let $\mathfrak{h}$ be a Cartan subalgebra of $\mathfrak{g}$. Let $\Delta \subset \mathfrak{h}^{*}$ be the root system, and let $W \subset G L(\mathfrak{h})$ be the Weyl group. We denote the set of positive roots by $\Delta^{+}$and the set of simple roots by $\left\{\alpha_{i}\right\}_{i \in I_{0}}$, where $I_{0}$ is an index set. For $i \in I_{0}$ we denote the simple reflection corresponding to $\alpha_{i}$ by $s_{i} \in W$. Let (,) : $\mathfrak{g} \times \mathfrak{g} \rightarrow \mathbb{C}$ be the invariant symmetric bilinear form such that $(\alpha, \alpha)=2$ for any $\alpha \in \Delta$. Set $a_{i j}=\left(\alpha_{i}, \alpha_{j}\right)$. The matrix $\left(a_{i j}\right)_{i, j \in l_{0}}$ is called the Cartan matrix of type $E_{6}$ or $E_{7}$. For $\alpha \in \Delta$ we denote the corresponding root space by $\mathfrak{g}_{\alpha}$. Set $\mathfrak{n}^{+}=\bigoplus_{\alpha \in \Delta^{+}} \mathfrak{g}_{\alpha}, \mathfrak{n}^{-}=\bigoplus_{\alpha \in \Delta^{+}} \mathfrak{g}_{-\alpha}$. For a subset $I \subset I_{0}$ we define

$$
\Delta_{I}=\Delta \cap \sum_{i \in I} \mathbb{Z} \alpha_{i}, \quad W_{I}=\left\langle s_{i} \mid i \in I\right\rangle .
$$

We set

$$
\mathfrak{l}_{I}=\mathfrak{h} \oplus\left(\bigoplus_{\alpha \in \Delta_{I}} \mathfrak{g}_{\alpha}\right), \quad \mathfrak{n}_{I}^{+}=\bigoplus_{\alpha \in \Delta^{+} \backslash \Delta_{I}} \mathfrak{g}_{\alpha}, \quad \mathfrak{n}_{I}^{-}=\bigoplus_{\alpha \in \Delta^{+} \backslash \Delta_{I}} \mathfrak{g}_{-\alpha} .
$$

Let $G$ be a connected algebraic group with Lie algebra $\mathfrak{g}$. We denote by $L_{I}$ the subgroup of $G$ corresponding to $\mathfrak{l}_{I}$. Then $L_{I}$ acts on $\mathfrak{n}_{I}^{ \pm}$via the adjoint action.

The quantized enveloping algebra $U_{q}(\mathfrak{g})$ (Drinfel'd [1], Jimbo [3]) is an associative algebra over the rational function field $\mathbb{C}(q)$ generated by the elements $E_{i}, F_{i}$, $K_{i}, K_{i}^{-1}\left(i \in I_{0}\right)$ satisfying the following fundamental relations:

$$
\begin{array}{ll}
K_{i} K_{j}=K_{j} K_{i}, \quad K_{i} K_{i}^{-1}=K_{i}^{-1} K_{i}=1, \\
K_{i} E_{j}=q^{a_{i j}} E_{j} K_{i}, \quad K_{i} F_{j}=q^{-a_{i j}} F_{j} K_{i}, \\
E_{i} F_{j}-F_{j} E_{i}=\delta_{i j} \frac{K_{i}-K_{i}^{-1}}{q-q^{-1},} & \\
E_{i} E_{j}=E_{j} E_{i} & \left(i \neq j, a_{i j}=0\right) \\
E_{i}^{2} E_{j}-\left(q+q^{-1}\right) E_{i} E_{j} E_{i}+E_{j} E_{i}^{2}=0 & \left(i \neq j, a_{i j}=-1\right), \\
F_{i} F_{j}=F_{j} F_{i} & \left(i \neq j, a_{i j}=0\right) \\
F_{i}^{2} F_{j}-\left(q+q^{-1}\right) F_{i} F_{j} F_{i}+F_{j} F_{i}^{2}=0 & \left(i \neq j, a_{i j}=-1\right)
\end{array}
$$

A Hopf algebra structure on $U_{q}(\mathfrak{g})$ is defined as follows. The comultiplication $\Delta: U_{q}(\mathfrak{g}) \rightarrow U_{q}(\mathfrak{g}) \otimes U_{q}(\mathfrak{g})$ is the algebra homomorphism satisfying

$$
\Delta\left(K_{i}\right)=K_{i} \otimes K_{i}, \quad \Delta\left(E_{i}\right)=E_{i} \otimes K_{i}^{-1}+1 \otimes E_{i}, \quad \Delta\left(F_{i}\right)=F_{i} \otimes 1+K_{i} \otimes F_{i}
$$

The counit $\epsilon: U_{q}(\mathfrak{g}) \rightarrow \mathbb{C}(q)$ is the algebra homomorphism satisfying

$$
\epsilon\left(K_{i}\right)=1, \quad \epsilon\left(E_{i}\right)=\epsilon\left(F_{i}\right)=0 .
$$

The antipode $S: U_{q}(\mathfrak{g}) \rightarrow U_{q}(\mathfrak{g})$ is the algebra antiautomorphism satisfying

$$
S\left(K_{i}\right)=K_{i}^{-1}, \quad S\left(E_{i}\right)=-E_{i} K_{i}, \quad S\left(F_{i}\right)=-K_{i}^{-1} F_{i}
$$

Using the Hopf algebra structure, we define the adjoint action of $U_{q}(\mathfrak{g})$ on $U_{q}(\mathfrak{g})$ as follows. For $x, y \in U_{q}(\mathfrak{g})$ write $\Delta(x)=\sum_{k} x_{k}^{1} \otimes x_{k}^{2}$ and set $\operatorname{ad}(x) y=\sum_{k} x_{k}^{1} y S\left(x_{k}^{2}\right)$. Then ad : $U_{q}(\mathfrak{g}) \rightarrow \operatorname{End}_{\mathbb{C}(q)}\left(U_{q}(\mathfrak{g})\right)$ is an algebra homomorphism. For $x, y, z \in U_{q}(\mathfrak{g})$ we have $\operatorname{ad}(x)(y z)=\sum_{k}\left(\operatorname{ad}\left(x_{k}^{1}\right) y\right)\left(\operatorname{ad}\left(x_{k}^{2}\right) z\right)$, where $\Delta(x)=\sum_{k} x_{k}^{1} \otimes x_{k}^{2}$.

We define subalgebras $U_{q}\left(\mathfrak{n}^{-}\right)$and $U_{q}\left(\mathrm{I}_{I}\right)$ for $I \subset I_{0}$ by

$$
U_{q}\left(\mathfrak{n}^{-}\right)=\left\langle F_{i} \mid i \in I_{0}\right\rangle, \quad U_{q}\left(l_{l}\right)=\left\langle E_{i}, F_{i}, K_{j}, K_{j}^{-1} \mid i \in I, j \in I_{0}\right\rangle
$$

For $i \in I_{0}$ we define an algebra automorphism $T_{i}$ of $U_{q}(\mathfrak{g})$ by

$$
\begin{aligned}
& T_{i}\left(K_{j}\right)=K_{j} K_{i}^{-a_{i j}}, \\
& T_{i}\left(E_{j}\right)= \begin{cases}-F_{i} K_{i} & (i=j) \\
E_{j} & \left(i \neq j, a_{i j}=0\right) \\
E_{i} E_{j}-q^{-1} E_{j} E_{i}\left(i \neq j, a_{i j}=-1\right),\end{cases} \\
& T_{i}\left(F_{j}\right)= \begin{cases}-K_{i}^{-1} E_{i} & (i=j) \\
F_{j} & \left(i \neq j, a_{i j}=0\right) \\
F_{j} F_{i}-q F_{i} F_{j}\left(i \neq j, a_{i j}=-1\right)\end{cases}
\end{aligned}
$$

(see Lusztig [6]). For $w \in W$ choose a reduced expression $w=s_{i_{1}} \cdots s_{i_{r}}$ and set $T_{w}=$ $T_{i_{1}} \cdots T_{i_{r}}$. It is known that $T_{w}$ does not depend on the choice of a reduced expression.

We shall use the following later (see Lusztig [6]).
Lemma 1.1. If $w\left(\alpha_{i}\right)=\alpha_{j}$ for $w \in W$ and $i, j \in I_{0}$, then we have $T_{w}\left(F_{i}\right)=F_{j}$.
For $I \subset I_{0}$ let $w_{I}$ be the longest element of $W_{I}$ and let $w_{0}$ be the longest element of $W$. Choose a reduced expression $w_{I} w_{0}=s_{i_{1}} \cdots s_{i_{r}}$ of $w_{I} w_{0}$ and set

$$
\beta_{j}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{j-1}}\left(\alpha_{i_{j}}\right), \quad Y_{j}=Y_{\beta_{j}}=T_{i_{1}} \cdots T_{i_{j-1}}\left(F_{i_{j}}\right)
$$

for $1 \leq j \leq r$. Then it is known that $\left\{\beta_{j} \mid 1 \leq j \leq r\right\}=\Delta^{+} \backslash \Delta_{I}$. Set

$$
U_{q}\left(\mathfrak{n}_{I}^{-}\right)=\sum_{d_{j} \geq 0} \mathbb{C}(q) Y_{1}^{d_{1}} \cdots Y_{r}^{d_{r}} .
$$

Then $\left\{Y_{1}^{d_{1}} \cdots Y_{r}^{d_{r}} \mid d_{j} \in \mathbb{Z}_{\geq 0}, 1 \leq j \leq r\right\}$ is a basis of $U_{q}\left(\mathfrak{n}_{I}^{-}\right)$and $U_{q}\left(\mathfrak{n}_{I}^{-}\right)$is a subalgebra of $U_{q}\left(\mathfrak{n}^{-}\right)$. we have

$$
U_{q}\left(\mathfrak{n}_{I}^{-}\right)=U_{q}\left(\mathfrak{n}^{-}\right) \cap T_{w_{l}}^{-1} U_{q}\left(\mathfrak{n}^{-}\right)
$$

and $U_{q}\left(\mathfrak{n}_{I}^{-}\right)$does not depend on the choice of a reduced expression of $w_{I} w_{0}$ (see Lusztig [6]).

If $\mathfrak{n}_{I}^{+} \neq\{0\},\left[\mathfrak{n}_{I}^{+}, \mathfrak{n}_{I}^{+}\right]=\{0\}$, then $Y_{\beta}$ for $\beta \in \Delta^{+} \backslash \Delta_{I}$ does not depend on the choice of a reduced expression of $w_{I} w_{0}$ (see [4]). In this case we denote the $\mathbb{C}(q)$ algebra $U_{q}\left(\mathfrak{n}_{I}^{-}\right)$by $A_{q}$. We can regard it as a quantum deformation of the coordinate algebra $A=\mathbb{C}\left[\mathfrak{n}_{I}^{+}\right]$of $\mathfrak{n}_{I}^{+}$as explained in [4].

## 2. Case of type $\boldsymbol{E}_{\mathbf{6}}$

Let $\mathfrak{g}$ be a simple Lie algebra of type $E_{6}$. We shall use the labelling of the vertices of the Dynkin diagram 2.

Dynkin diagram 2.
Hence we have $I_{0}=\{1,2,3,4,5,6\}$. Set $I=\{2,3,4,5,6\}$. In this case we have $\mathfrak{n}_{I}^{+} \neq$ $\{0\},\left[\mathfrak{n}_{I}^{+}, \mathfrak{n}_{I}^{+}\right]=\{0\}$. Then $\mathfrak{l}_{I}$ is isomorphic to $\mathbb{C} \oplus \mathfrak{o}(10, \mathbb{C})$ and $\mathfrak{n}_{I}^{+}$is a 16 -dimensional irreducible prehomogeneous vector space. There are three $L_{I}$-orbits $\{0\}, C_{0}, O$ on $\mathfrak{n}_{I}^{+}$ satisfying $\{0\} \subset \overline{C_{0}} \subset \bar{O}$. Let $J_{C_{0}} \subset \mathbb{C}\left[\mathfrak{n}_{I}^{+}\right]$be the defining ideal of the closure of $C_{0}$, and let $J_{C_{0}}^{0}$ denote the subspace of $J_{C_{0}}$ consisting of the polynomials in $J_{C_{0}}$ with homogeneous degree 2. Then $J_{C_{0}}^{0}$ is a ten-dimensional irreducible $\mathfrak{l}_{1}$-module, and it generates the ideal $J_{C_{0}}$.

We fix a reduced expression

$$
w_{I} w_{0}=s_{1} s_{2} s_{3} s_{4} s_{5} s_{3} s_{2} s_{1} s_{6} s_{5} s_{3} s_{2} s_{4} s_{3} s_{5} s_{6}
$$

of $w_{I} w_{0}$ and define the elements $Y_{i}(i \in \Lambda=\{1,2, \ldots, 16\})$ as in Section 1.
Set $I_{0}^{\prime}=\{1,2,3,4,5\}, I^{\prime}=\{2,3,4,5\}, \Lambda^{\prime}=\{1,2, \ldots, 8\}$. Then $\left\{\alpha_{i}\right\}_{i \in I_{0}^{\prime}}$ is a set of simple roots of type $D_{5}$. Let $\mathfrak{g}^{\prime}$ be the simple subalgebra of $\mathfrak{g}$ corresponding to $I_{0}^{\prime}$. We choose a reduced expression $w_{I^{\prime}} w_{I_{0}^{\prime}}=s_{1} s_{2} s_{3} s_{4} s_{5} s_{3} s_{2} s_{1}$ of $w_{I^{\prime}} w_{I_{0}^{\prime}}$. The elements $Y_{i}(i \in$ $\Lambda^{\prime}$ ) can be computed inside $U_{q}\left(\mathfrak{g}^{\prime}\right)$.

Let $\beta_{j}=\sum_{i \in I_{0}} m_{i}^{j} \alpha_{i}$ and set $\mathbf{m}^{j}=\left(m_{1}^{j}, \ldots, m_{6}^{j}\right)$ for $j \in \Lambda$. Then we have

$$
\begin{array}{lll}
\mathbf{m}^{1}=(1,0,0,0,0,0), & \mathbf{m}^{2}=(1,1,0,0,0,0), & \mathbf{m}^{3}=(1,1,1,0,0,0), \\
\mathbf{m}^{4}=(1,1,1,1,0,0), & \mathbf{m}^{5}=(1,1,1,0,1,0), & \mathbf{m}^{6}=(1,1,1,1,1,0), \\
\mathbf{m}^{7}=(1,1,2,1,1,0), & \mathbf{m}^{8}=(1,2,2,1,1,0), & \mathbf{m}^{9}=(1,1,1,0,1,1), \\
\mathbf{m}^{10}=(1,1,1,1,1,1), & \mathbf{m}^{11}=(1,1,2,1,1,1), & \mathbf{m}^{12}=(1,2,2,1,1,1), \\
\mathbf{m}^{13}=(1,1,2,1,2,1), & \mathbf{m}^{14}=(1,2,2,1,2,1), & \mathbf{m}^{15}=(1,2,3,1,2,1), \\
\mathbf{m}^{16}=(1,2,3,2,2,1) . & &
\end{array}
$$

If $\left(\beta_{j}, \alpha_{k}\right)=-1$ for $j \in \Lambda$ and $k \in I$, then $s_{k}\left(\beta_{j}\right)=\beta_{j}+\alpha_{k} \in \Delta^{+}$. Since $k \neq 1$ and $m_{1}^{j}=1$, we have $\beta_{j}+\alpha_{k} \notin \Delta_{I}$. Therefore there exists $l \in \Lambda$ satisfying $\beta_{j}+\alpha_{k}=\beta_{l}$. Conversely if $\beta_{j}+\alpha_{k}=\beta_{l}(j, l \in \Lambda, k \in I)$, then we have ( $\left.\beta_{j}, \alpha_{k}\right)=-1, s_{k}\left(\beta_{j}\right)=\beta_{l}$.

There exist 20 triplets $(k, j, l) \in I \times \Lambda \times \Lambda$ satisfying $\beta_{j}+\alpha_{k}=\beta_{l}$. The triplets are the following: $(2,1,2),(3,2,3),(4,3,4),(5,3,5),(5,4,6),(4,5,6),(3,6,7)$, $(2,7,8),(6,5,9),(4,9,10),(3,10,11),(2,11,12),(5,11,13),(5,12,14),(2,13,14)$, $(3,14,15),(4,15,16),(6,6,10),(6,7,11),(6,8,12)$.

For $k \in I, j \in \Lambda$, we have $\beta_{j}-2 \alpha_{k}, \beta_{j}+2 \alpha_{k} \notin \Delta^{+} \backslash \Delta_{I}$.
Lemma 2.1. Let $\beta, \beta^{\prime} \in \Delta^{+} \backslash \Delta_{I}$ satisfying $\beta+\alpha_{k}=\beta^{\prime}(k \in I)$. Then we can choose a reduced expression $w_{1} w_{0}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{16}}$ and $p \in \Lambda$ satisfying

$$
\begin{aligned}
& \beta=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}}\left(\alpha_{i_{p}}\right), \beta^{\prime}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}} s_{i_{p}}\left(\alpha_{i_{p+1}}\right),\left(\alpha_{i_{p}}, \alpha_{i_{p+1}}\right)=-1, \\
& \alpha_{k}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}}\left(\alpha_{i_{p+1}}\right) .
\end{aligned}
$$

Proof. Among the 20 triplets $(k, j, l)$ satisfying $\beta_{j}+\alpha_{k}=\beta_{l}(k \in I, j, k \in \Lambda)$, the 12 triplets satisfy $l=j+1,\left(\alpha_{i j}, \alpha_{i j+1}\right)=-1$. Therefore it is sufficient to deal with the remaining 8 cases. In the cases $(k, j, l)=(5,3,5),(5,4,6),(5,11,13),(5,12,14)$, the reduced expression

$$
w_{I} w_{0}=s_{1} s_{2} s_{3} s_{5} s_{4} s_{3} s_{2} s_{1} s_{6} s_{5} s_{3} s_{4} s_{2} s_{3} s_{5} s_{6}
$$

of $w_{I} w_{0}$ with $p=3,5,11,13$ respectively satisfies the required properties. In the cases $(k, j, l)=(6,5,9),(6,6,10),(6,7,11),(6,8,12)$, the reduced expression

$$
w_{I} w_{0}=s_{1} s_{2} s_{3} s_{4} s_{5} s_{6} s_{3} s_{5} s_{2} s_{3} s_{1} s_{2} s_{4} s_{3} s_{5} s_{6}
$$

of $w_{I} w_{0}$ with $p=5,7,9,11$ respectively satisfies the required properties.
It is known that $U_{q}\left(\mathfrak{n}_{I}^{+}\right)^{1}=\bigoplus_{\beta \in \Delta^{+} \backslash \Delta_{I}} \mathbb{C}(q) Y_{\beta}$ is an irreducible $U_{q}\left(l_{I}\right)$-module. (see [4])

Lemma 2.2. For $k \in I, j \in \Lambda$, we have

$$
\operatorname{ad}\left(F_{k}\right) Y_{j}=\left\{\begin{array}{l}
Y_{l} \text { if there exists } l \in \Lambda \text { such that } \beta_{l}=\beta_{j}+\alpha_{k}, \\
0 \text { otherwise }
\end{array}\right.
$$

$$
\operatorname{ad}\left(E_{k}\right) Y_{j}=\left\{\begin{array}{l}
Y_{l} \text { if there exists } l \in \Lambda \text { such that } \beta_{l}=\beta_{j}-\alpha_{k} \\
0 \text { otherwise }
\end{array}\right.
$$

Proof. Since $\bigoplus_{j \in \Lambda} \mathbb{C}(q) Y_{j}$ is a $U_{q}\left(l_{l}\right)$-module, we have $\operatorname{ad}\left(F_{k}\right) Y_{j}=0$ if $\beta_{j}+\alpha_{k} \notin$ $\Delta^{+} \backslash \Delta_{I}$, and we have $\operatorname{ad}\left(E_{k}\right) Y_{j}=0$ if $\beta_{j}-\alpha_{k} \notin \Delta^{+} \backslash \Delta_{I}$.

We shall show $\operatorname{ad}\left(F_{k}\right) Y_{\beta}=Y_{\beta^{\prime}}$ for $\beta, \beta^{\prime} \in \Delta^{+} \backslash \Delta_{I}$ and $k \in I$ satisfying $\beta^{\prime}=$ $\beta+\alpha_{k}$. By Lemma 2.1 we can choose a reduced expression of $w_{I} w_{0}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{16}}$ satisfying $\beta=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}}\left(\alpha_{i_{p}}\right), \beta^{\prime}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}} s_{i_{p}}\left(\alpha_{i_{p+1}}\right),\left(\alpha_{i_{p}}, \alpha_{i_{p+1}}\right)=-1$. Then we can write $Y_{\beta}=T_{i_{1}} T_{i_{2}} \cdots T_{i_{p-1}}\left(F_{i_{p}}\right), Y_{\beta^{\prime}}=T_{i_{1}} T_{i_{2}} \cdots T_{i_{p-1}} T_{i_{p}}\left(F_{i_{p+1}}\right)$. Since $\left(\alpha_{i_{\rho}}, \alpha_{i_{p+1}}\right)=-1$, we have $T_{i_{p}}\left(F_{i_{p+1}}\right)=F_{i_{p+1}} F_{i_{p}}-q F_{i_{p}} F_{i_{p+1}}$. Moreover, since $\alpha_{k}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}}\left(\alpha_{i_{p+1}}\right)$, we have $T_{i_{1}} T_{i_{2}} \cdots T_{i_{p-1}}\left(F_{i_{p+1}}\right)=F_{k}$ by Lemma 1.1, and hence

$$
\begin{aligned}
Y_{\beta^{\prime}} & =T_{i_{1}} T_{i_{2}} \cdots T_{i_{p-1}} T_{i_{p}}\left(F_{i_{p+1}}\right) \\
& =T_{i_{1}} T_{i_{2}} \cdots T_{i_{p-1}}\left(F_{i_{p+1}} F_{i_{p}}-q F_{i_{p}} F_{i_{p+1}}\right)=F_{k} Y_{\beta}-q Y_{\beta} F_{k} .
\end{aligned}
$$

Since $\left(\beta, \alpha_{k}\right)=-1$, we have $\operatorname{ad}\left(F_{k}\right) Y_{\beta}=F_{k} Y_{\beta}-q Y_{\beta} F_{k}$. Hence we have $\operatorname{ad}\left(F_{k}\right) Y_{\beta}=Y_{\beta^{\prime}}$.
Let us show $\operatorname{ad}\left(E_{k}\right) Y_{\beta}=Y_{\beta^{\prime}}$ for $\beta, \beta^{\prime} \in \Delta^{+} \backslash \Delta_{I}$ and $k \in I$ satisfying $\beta^{\prime}=\beta-\alpha_{k}$. By the above argument we have $Y_{\beta}=\operatorname{ad}\left(F_{k}\right) Y_{\beta^{\prime}}=F_{k} Y_{\beta^{\prime}}-q Y_{\beta^{\prime}} F_{k}$. Since $\beta^{\prime}-\alpha_{k}=\beta-$ $2 \alpha_{k} \notin \Delta^{+} \backslash \Delta_{I}$, we have $\operatorname{ad}\left(E_{k}\right) Y_{\beta^{\prime}}=0$, and hence $E_{k} Y_{\beta^{\prime}}=Y_{\beta^{\prime}} E_{k}$. Since $\left(\beta^{\prime}, \alpha_{k}\right)=-1$, we have $K_{k} Y_{\beta^{\prime}}=q Y_{\beta^{\prime}} K_{k}$. Hence we have

$$
\begin{aligned}
\operatorname{ad}\left(E_{k}\right) Y_{\beta} & =\left(E_{k} Y_{\beta}-Y_{\beta} E_{k}\right) K_{k}=\left(E_{k}\left(F_{k} Y_{\beta^{\prime}}-q Y_{\beta^{\prime}} F_{k}\right)-\left(F_{k} Y_{\beta^{\prime}}-q Y_{\beta^{\prime}} F_{k}\right) E_{k}\right) K_{k} \\
& =\left(\frac{K_{k}-K_{k}^{-1}}{q-q^{-1}} Y_{\beta^{\prime}}-q Y_{\beta^{\prime}} \frac{K_{k}-K_{k}^{-1}}{q-q^{-1}}\right) K_{k}=\left(Y_{\beta^{\prime}} K_{k}^{-1}\right) K_{k}=Y_{\beta^{\prime}}
\end{aligned}
$$

Next we shall consider quadratic fundamental relations among the elements $Y_{i}$. Since we have

$$
\sum_{i, j \in \Lambda} \mathbb{C}(q) Y_{i} Y_{j}=\bigoplus_{s \leq t} \mathbb{C}(q) Y_{s} Y_{t}
$$

we can write

$$
Y_{i} Y_{j}=\sum_{\substack{s \leq 1 \\ \beta_{i}+\beta_{j}=\beta_{s}+\beta_{t}}} a_{s, t}^{i, j} Y_{s} Y_{t} \quad\left(a_{s, t}^{i, j} \in \mathbb{C}(q)\right)
$$

for $i>j$ (see [4]). Hence if $\beta_{i}+\beta_{j}$ does not have another decomposition $\beta+\beta^{\prime}\left(\beta, \beta^{\prime} \in\right.$ $\left.\Delta^{+} \backslash \Delta_{I}, \beta_{i}+\beta_{j}=\beta+\beta^{\prime}\right)$ then we have $Y_{i} Y_{j}=a_{i, j} Y_{j} Y_{i}$ for some $a_{i, j} \in \mathbb{C}(q)$. We denote the set of weights of the ten-dimensional irreducible highest weight $\mathfrak{l}_{I}$-module $J_{C_{0}}^{0}$ with highest weight $-\beta_{1}-\beta_{8}$ by $\Gamma$. For $\beta, \beta^{\prime} \in \Delta^{+} \backslash \Delta_{I}$ a weight $\beta+\beta^{\prime}$ has another decomposition if and only if we have $-\left(\beta+\beta^{\prime}\right) \in \Gamma$. We fix a bijection
$\{1,2, \ldots, 10\} \ni n \mapsto-\delta_{n} \in \Gamma$ such that if $\delta_{m}-\delta_{n} \in \sum_{i \in I_{0}} \mathbb{Z}_{\geq 0} \alpha_{i}$, then $n \leq m$. For each $n$ there exist exactly four pairs $(i, j) \in \Lambda^{2}$ such that $i<j, \beta_{i}+\beta_{j}=\delta_{n}$. We denote them by $\left(i_{1}^{n}, j_{1}^{n}\right),\left(i_{2}^{n}, j_{2}^{n}\right),\left(i_{3}^{n}, j_{3}^{n}\right),\left(i_{4}^{n}, j_{4}^{n}\right) \in \Lambda^{2}$ where $i_{4}^{n}<i_{3}^{n}<i_{2}^{n}<i_{1}^{n}$. Set $\mathbf{A}(n)=\left(i_{4}^{n}, i_{3}^{n}, i_{2}^{n}, i_{1}^{n}, j_{1}^{n}, j_{2}^{n}, j_{3}^{n}, j_{4}^{n}\right) \in \Lambda^{8}(1 \leq n \leq 10)$. Then we have

$$
\begin{array}{ll}
\mathbf{A}(1)=(1,2,3,4,5,6,7,8), & \mathbf{A}(2)=(1,2,3,4,9,10,11,12) \\
\mathbf{A}(3)=(1,2,5,6,9,10,13,14), & \mathbf{A}(4)=(1,3,5,7,9,11,13,15) \\
\mathbf{A}(5)=(2,3,5,8,9,12,14,15), & \mathbf{A}(6)=(1,4,6,7,10,11,13,16) \\
\mathbf{A}(7)=(2,4,6,8,10,12,14,16), & \mathbf{A}(8)=(3,4,7,8,11,12,15,16) \\
\mathbf{A}(9)=(5,6,7,8,13,14,15,16), & \mathbf{A}(10)=(9,10,11,12,13,14,15,16) .
\end{array}
$$

We denote the set $\left\{i_{4}^{n}, i_{3}^{n}, i_{2}^{n}, i_{1}^{n}, j_{1}^{n}, j_{2}^{n}, j_{3}^{n}, j_{4}^{n}\right\}$ by $|\mathbf{A}(n)|$ for $1 \leq n \leq 10$. For any $i, j \in \Lambda$ there exists $n$ satisfying $i, j \in|\mathbf{A}(n)|$.

Set

$$
\mathcal{A}=\left\{\left(k, n, n^{\prime}\right) \in I \times \Lambda \times \Lambda \mid \delta_{n}+\alpha_{k}=\delta_{n^{\prime}}\right\}
$$

Then

$$
\begin{aligned}
& \mathcal{A}=\{(6,1,2),(5,2,3),(3,3,4),(2,4,5),(4,4,6) \\
&(2,6,7),(4,5,7),(3,7,8),(5,8,9),(6,9,10)\}
\end{aligned}
$$

For any $n \in\{2,3, \ldots, 10\}$ we can take a sequence $\left(\left(k_{1}, n_{1}, n_{1}^{\prime}\right), \ldots,\left(k_{s}, n_{s}, n_{s}^{\prime}\right)\right)$ of $\mathcal{A}$ satisfying $n_{1}=1, n_{s}^{\prime}=n, n_{j}^{\prime}=n_{j+1}(1 \leq j \leq s-1)$.

For $\left(k, n, n^{\prime}\right) \in \mathcal{A}$ and $m \in\{1,2,3,4\}$, we have either $\left(\mathrm{P}_{m}^{+}\right) \quad\left(\beta_{i_{m}^{n}}, \alpha_{k}\right)=0, i_{m}^{n^{\prime}}=i_{m}^{n},\left(\beta_{j_{m}^{n}}, \alpha_{k}\right)=-1, \beta_{j_{m}^{n^{\prime}}}=\beta_{j_{m}^{n}}+\alpha_{k}$
or
$\left(\mathrm{P}_{m}^{-}\right) \quad\left(\beta_{i_{m}^{n}}, \alpha_{k}\right)=-1, \beta_{i_{m}^{n^{\prime}}}=\beta_{i_{m}^{n}}+\alpha_{k},\left(\beta_{j_{m}^{n}}, \alpha_{k}\right)=0, j_{m}^{n^{\prime}}=j_{m}^{n}$.
Proposition 2.3. For any $i, j \in \Lambda$ satisfying $i<j$, we have
(Q6)

$$
Y_{i} Y_{j}=\left\{\begin{array}{lc}
Y_{j} Y_{i} & \text { if there exists } n \text { such that } i=i_{1}^{n}, j=j_{1}^{n}, \\
Y_{j_{2}^{n}} Y_{i_{2}^{n}}+\left(q-q^{-1}\right) Y_{i_{1}^{n}} Y_{j_{1}^{n}} \text { if there exists } n \text { such that } i=i_{2}^{n}, j=j_{2}^{n}, \\
Y_{j_{m}^{n}} Y_{i_{m}^{n}}+q Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}}-q^{-1} Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}} \\
\text { if there exist } n, m \in\{3,4\} \text { such that } i=i_{m}^{n}, j=j_{m}^{n}, \\
q Y_{j} Y_{i} & \text { otherwise. }
\end{array}\right.
$$

Proof. Since there exists some $n$ satisfying $i, j \in|\mathbf{A}(n)|$ for any $i, j \in \Lambda$, it is sufficient to show that for any $1 \leq n \leq 10$ the elements $Y_{i_{m}^{n}}, Y_{j_{m}^{n}}(1 \leq m \leq 4)$ satisfy
the following relations.

$$
\left\{\begin{array}{l}
Y_{i_{1}^{n}} Y_{j_{1}^{n}}=Y_{j_{1}^{n}} Y_{i_{1}^{n}}  \tag{Rn}\\
Y_{i_{m}^{n}} Y_{j_{m}^{n}}=Y_{j_{m}^{n}} Y_{i_{m}^{n}}+q Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}}^{n}-q^{-1} Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}}^{n}(2 \leq m \leq 4) \\
Y_{l_{1}} Y_{l_{2}}=q Y_{l_{2}} Y_{l_{1}} \\
\quad\left(l_{1}, l_{2} \in|\mathbf{A}(n)|, l_{1}<l_{2},\left(l_{1}, l_{2}\right) \neq\left(i_{m}^{n}, j_{m}^{n}\right)(1 \leq m \leq 4)\right)
\end{array}\right.
$$

When $n=1$, the elements $Y_{i}(1 \leq i \leq 8)$ satisfy the same relations as those for type $D_{5}$, hence the relations (R1) hold.

For any $m>1$ there exists a sequence $\left(\left(k_{1}, n_{1}, n_{1}^{\prime}\right), \ldots,\left(k_{s}, n_{s}, n_{s}^{\prime}\right)\right)$ of $\mathcal{A}$ satisfying $n_{1}=1, n_{s}^{\prime}=m, n_{j}^{\prime}=n_{j+1}(1 \leq j \leq s-1)$, and hence it is sufficient to show the relations ( $\mathrm{R} n^{\prime}$ ) for ( $k, n, n^{\prime}$ ) $\in \mathcal{A}$ assuming the relations ( $\mathrm{R} n$ ).

Let $\left(k, n, n^{\prime}\right) \in \mathcal{A}$. Assume that the relations ( $\mathrm{R} n$ ) hold.
We first show that the relation ( $\mathrm{R} n^{\prime}, 1$ ) holds. If the condition ( $\mathrm{P}_{1}^{+}$) is satisfied, then we have $Y_{i_{1}^{\prime}}=Y_{i_{1}^{n}}, F_{k} Y_{i_{1}^{n}}=Y_{i_{1}^{n}} F_{k}, Y_{j_{1}^{n^{\prime}}}=\operatorname{ad}\left(F_{k}\right) Y_{j_{1}^{n}}=F_{k} Y_{j_{1}^{n}}-q Y_{j_{1}^{n}} F_{k}$. Since $Y_{i_{1}^{n}} Y_{j_{1}^{n}}=$ $Y_{j_{1}^{n}} Y_{i_{1}^{n}}$, we have

$$
\begin{aligned}
Y_{i_{1}^{\prime}} Y_{j_{1}^{\prime}} & =Y_{i_{1}^{n}} \operatorname{ad}\left(F_{k}\right) Y_{j_{1}^{n}}=Y_{i 1}^{n}\left(F_{k} Y_{j_{1}^{n}}-q Y_{j_{1}^{n}} F_{k}\right) \\
& =\left(F_{k} Y_{j_{1}^{n}}-q Y_{j_{1}^{n}} F_{k}\right) Y_{i 1}^{n}=Y_{j_{1}^{\prime}} Y_{i_{1}^{n_{1}^{\prime}}} .
\end{aligned}
$$

If the condition ( $\mathrm{P}_{1}^{-}$) is satisfied, then we can prove the formula ( $\mathrm{Rn}^{\prime}, 1$ ) similarly.
Next we prove the formula ( $\mathrm{R}^{\prime}, 2$ ). Assume the condition $\left(\mathrm{P}_{m}^{+}\right)$is satisfied, then we have

$$
\begin{aligned}
Y_{i_{m}^{\prime}} Y_{j_{m}^{n^{\prime}}}= & Y_{i_{m}^{n}}\left(F_{k} Y_{j_{m}^{n}}-q Y_{j_{m}^{n}} F_{k}\right) \\
= & F_{k} Y_{j_{m}^{n}} Y_{i_{m}^{n}}-q Y_{j_{m}^{m}} F_{k} Y_{i_{m}^{n}} \\
& +q\left(F_{k} Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}}-q Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}} F_{k}\right) \\
& -q^{-1}\left(F_{k} Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}}^{n}-q Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}}^{n} F_{k}\right) .
\end{aligned}
$$

If the condition $\left(\mathrm{P}_{m-1}^{+}\right)$is satisfied, then we have

$$
\begin{aligned}
& F_{k} Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}}-q Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}} F_{k}=Y_{j_{m-1}^{n}}\left(F_{k} Y_{i m-1}^{n}-q Y_{i_{m-1}^{n}} F_{k}\right)=Y_{j_{m-1}^{n^{\prime}}} Y_{i_{m-1}^{\prime \prime}}, \\
& F_{k} Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}}-q Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}} F_{k}=\left(F_{k} Y_{i_{m-1}^{n}}^{n}-q Y_{i_{m-1}^{n}} F_{k}\right) Y_{j_{m-1}^{n}}=Y_{i_{m-1}^{\prime \prime}}^{\prime \prime} Y_{j_{m-1}^{\prime \prime}}^{\prime},
\end{aligned}
$$

and if the condition $\left(\mathrm{P}_{m-1}^{-}\right)$is satisfied, then we have

$$
\begin{aligned}
& F_{k} Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}}^{n}-q Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}} F_{k}=\left(F_{k} Y_{j_{m-1}^{n}}-q Y_{j_{m-1}^{n}} F_{k}\right) Y_{i}^{n}=Y_{j_{m-1}^{\prime \prime}} Y_{i_{m-1}^{\prime}}, \\
& F_{k} Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}}-q Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}}^{n} F_{k}=Y_{i_{m-1}^{n}}\left(F_{k} Y_{j_{m-1}^{n}}-q Y_{j_{m-1}^{n}} F_{k}\right)=Y_{i_{m-1}^{n} n_{1}^{\prime}} Y_{j_{m-1}^{\prime \prime}} .
\end{aligned}
$$

Hence we have $Y_{i_{m}^{\prime}} Y_{j_{m}^{n^{\prime}}}=Y_{j_{m}^{n^{\prime}}} Y_{i_{m}^{n^{\prime}}}+q Y_{j_{m-1}^{n^{\prime}}} Y_{i i_{m-1}^{n^{\prime}}}-q^{-1} Y_{i_{m-1}^{n^{\prime}}} Y_{j_{m-1}^{n^{\prime}}}$. The formula ( $\mathrm{Rn}^{\prime}, 2$ ) is proved. When the condition $\left(\mathrm{P}_{m}^{-}\right)$is satisfied, we can prove it similarly.

Finally we prove the formula ( $\mathrm{R} n^{\prime}, 3$ ). Let $l_{1}^{\prime}, l_{2}^{\prime} \in\left|\mathbf{A}\left(n^{\prime}\right)\right|$ satisfying $l_{1}^{\prime}<l_{2}^{\prime}$ and $\left(l_{1}^{\prime}, l_{2}^{\prime}\right) \neq\left(i_{m}^{n^{\prime}}, j_{m}^{n^{\prime}}\right)$ for $1 \leq m \leq 4$. When $l_{p}^{\prime}=i_{m}^{n^{\prime}} \in\left|\mathbf{A}\left(n^{\prime}\right)\right|$ (resp. $l_{p}^{\prime}=j_{m}^{n^{\prime}}$ ), we denote $i_{m}^{n} \in|\mathbf{A}(n)|\left(\right.$ resp. $\left.j_{m}^{n}\right)$ by $l_{p}$ for $p=1,2$. Since $l_{1}<l_{2}$ and $\left(l_{1}, l_{2}\right) \neq\left(i_{m}^{n}, j_{m}^{n}\right)$ for $1 \leq m \leq 4$, we have $Y_{l_{1}} Y_{l_{2}}=q Y_{l_{2}} Y_{l_{1}}$. We have the following possibilities:
(1) $l_{1}^{\prime}=l_{1}, l_{2}^{\prime}=l_{2},\left(\beta_{l_{1}}, \alpha_{k}\right)=\left(\beta_{l_{2}}, \alpha_{k}\right)=0$,
(2) $l_{1}^{\prime}=l_{1},\left(\beta_{l_{1}}, \alpha_{k}\right)=0, \beta_{l_{2}^{\prime}}=\beta_{l_{2}}+\alpha_{k},\left(\beta_{l_{2}}, \alpha_{k}\right)=-1$,
(3) $\beta_{l_{1}^{\prime}}=\beta_{l_{1}}+\alpha_{k},\left(\beta_{l_{1}}, \alpha_{k}\right)=-1, l_{2}^{\prime}=l_{2},\left(\beta_{l_{2}}, \alpha_{k}\right)=0$,
(4) $\beta_{l_{1}^{\prime}}=\beta_{l_{1}}+\alpha_{k}, \beta_{l_{2}^{\prime}}=\beta_{l_{2}}+\alpha_{k},\left(\beta_{l_{1}}, \alpha_{k}\right)=\left(\beta_{l_{2}}, \alpha_{k}\right)=-1$.

In the case (1) the formula ( $\mathrm{Rn}^{\prime}, 3$ ) is obvious.
In the case (2) we have $F_{k} Y_{l_{1}}=Y_{l_{1}} F_{k}, Y_{l_{2}^{\prime}}=\operatorname{ad}\left(F_{k}\right) Y_{l_{2}}=F_{k} Y_{l_{2}}-q Y_{l_{2}} F_{k}$. Hence we have

$$
Y_{l_{1}}^{\prime} Y_{l_{2}^{\prime}}=Y_{l_{1}}\left(F_{k} Y_{l_{2}}-q Y_{l_{2}} F_{k}\right)=q\left(F_{k} Y_{l_{2}}-q Y_{l_{2}} F_{k}\right) Y_{l_{1}}=q Y_{l_{2}} Y_{l_{1}^{\prime}} .
$$

In the case (3) we can prove it similarly to the case (2).
In the case (4) we have $Y_{l_{p}^{\prime}}=F_{k} Y_{l_{p}}-q Y_{l_{p}} F_{k}$ for $p=1,2$. Since $\beta_{l_{p}^{\prime}}+\alpha_{k}=$ $\beta_{l_{p}}+2 \alpha_{k} \notin \Delta^{+} \backslash \Delta_{I}$ and $\left(\beta_{l_{p}^{\prime}}, \alpha_{k}\right)=1$, we have $\operatorname{ad}\left(F_{k}\right) Y_{l_{p}^{\prime}}=F_{k} Y_{l_{p}^{\prime}}-q^{-1} Y_{l_{p}^{\prime}} F_{k}=0$ for $p=1$, 2. Hence we have $F_{k} F_{k} Y_{l_{p}}-\left(q+q^{-1}\right) F_{k} Y_{l_{p}} F_{k}+Y_{l_{p}} F_{k} F_{k}=0, F_{k} Y_{l_{p}} F_{k}=$ $\left(q+q^{-1}\right)^{-1}\left(F_{k} F_{k} Y_{l_{p}}+Y_{l_{p}} F_{k} F_{k}\right)$ for $p=1,2$. By these formulas we have

$$
\begin{aligned}
Y_{l_{1}} Y_{l_{2}^{\prime}}= & \left(F_{k} Y_{l_{1}}-q Y_{l_{1}} F_{k}\right)\left(F_{k} Y_{l_{2}}-q Y_{l_{2}} F_{k}\right) \\
= & F_{k} Y_{l_{1}} F_{k} Y_{l_{2}}-q F_{k} Y_{l_{1}} Y_{l_{2}} F_{k}-q Y_{l_{1}} F_{k} F_{k} Y_{l_{2}}+q^{2} Y_{l_{1}} F_{k} Y_{l_{2}} F_{k} \\
= & \frac{1}{q+q^{-1}} F_{k} F_{k} Y_{l_{1}} Y_{l_{2}}+\frac{1}{q+q^{-1}} Y_{l_{1}} F_{k} F_{k} Y_{l_{2}}-q F_{k} Y_{l_{1}} Y_{l_{2}} F_{k}-q Y_{l_{1}} F_{k} F_{k} Y_{l_{2}} \\
& +\frac{q^{2}}{q+q^{-1}} Y_{l_{1}} F_{k} F_{k} Y_{l_{2}}+\frac{q^{2}}{q+q^{-1}} Y_{l_{1}} Y_{l_{2}} F_{k} F_{k} \\
= & \frac{1}{q+q^{-1}} F_{k} F_{k} Y_{l_{1}} Y_{l_{2}}-q F_{k} Y_{l_{1}} Y_{l_{2}} F_{k}+\frac{q^{2}}{q+q^{-1}} Y_{l_{1}} Y_{l_{2}} F_{k} F_{k} .
\end{aligned}
$$

Similarly we have

$$
Y_{l_{2}} Y_{l_{1}^{\prime}}=\frac{1}{q+q^{-1}} F_{k} F_{k} Y_{l_{2}} Y_{l_{1}}-q F_{k} Y_{l_{2}} Y_{l_{1}} F_{k}+\frac{q^{2}}{q+q^{-1}} Y_{l_{2}} Y_{l_{1}} F_{k} F_{k} .
$$

Since $Y_{l_{1}} Y_{l_{2}}=q Y_{l_{2}} Y_{l_{1}}$, we have $Y_{l_{1}^{\prime}} Y_{l_{2}^{\prime}}=q Y_{l_{2}^{\prime}} Y_{l_{1}^{\prime}}$.
By [4] and Proposition 2.3 we obtain the following:
Theorem 2.4. The formulas (Q6) give fundamental relations for the generator system $\left\{Y_{i}\right\}_{i \in \Lambda}$ of the algebra $A_{q}=U_{q}\left(\mathfrak{n}_{I}^{-}\right)$.

We shall construct a quantum deformation of the lowest degree part $J_{C_{0}}^{0}$ of the defining ideal $J_{C_{0}}$ and we shall give canonical generators of a quantum analogue of
$J_{C_{0}}$.
Set

$$
\psi_{n}=Y_{i_{4}^{n}} Y_{j_{4}^{n}}-q Y_{i_{3}^{n}} Y_{j_{3}^{n}}+q^{2} Y_{i_{2}^{n}} Y_{j_{2}^{n}}-q^{3} Y_{i_{1}^{1}} Y_{j_{1}^{n}},
$$

for $1 \leq n \leq 10$. Recall that $\mathbf{A}(n)=\left(i_{4}^{n}, i_{3}^{n}, i_{2}^{n}, i_{1}^{n}, j_{1}^{n}, j_{2}^{n}, j_{3}^{n}, j_{4}^{n}\right)$. Using the formulas (Rn,1), (Rn,2), we can write $\psi_{n}=Y_{j_{4}} Y_{i_{4}^{n}}-q^{-1} Y_{j_{3}} Y_{i_{3}^{n}}+q^{-2} Y_{j_{2}^{n}} Y_{i_{2}^{n}}-q^{-3} Y_{j_{1}} Y_{i_{1}^{n}}$.

## Lemma 2.5. We have

$$
\begin{aligned}
\operatorname{ad}\left(F_{k}\right) \psi_{n} & = \begin{cases}\psi_{n^{\prime}} \text { if there exists } n^{\prime} \text { such that } \delta_{n}+\alpha_{k}=\delta_{n^{\prime}}, \\
0 & \text { otherwise, }\end{cases} \\
\operatorname{ad}\left(E_{k}\right) \psi_{n} & = \begin{cases}\psi_{n^{\prime}} & \text { if there exists } n^{\prime} \text { such that } \delta_{n}-\alpha_{k}=\delta_{n^{\prime}}, \\
0 & \text { otherwise }\end{cases}
\end{aligned}
$$

for $k \in I$, and

$$
\operatorname{ad}\left(K_{k}\right) \psi_{n}=q^{-\left(\delta_{n}, \alpha_{k}\right)} \psi_{n}
$$

for $k \in I_{0}$.
Proof. Let $\left(k, n, n^{\prime}\right) \in \mathcal{A}$. We shall show $\operatorname{ad}\left(F_{k}\right) \psi_{n}=\psi_{n^{\prime}}$. If the condition ( $\mathbf{P}_{m}^{+}$) is satisfied, then we have $\operatorname{ad}\left(F_{k}\right) Y_{i m}^{n}=0, Y_{i n_{m}^{\prime}}=Y_{i m}, \operatorname{ad}\left(K_{k}\right) Y_{i_{m}^{n}}=Y_{i m}^{n} \operatorname{ad}\left(F_{k}\right) Y_{j_{m}^{n}}=Y_{j_{m}^{n^{\prime}}}$. Hence

$$
\operatorname{ad}\left(F_{k}\right)\left(Y_{i_{m}} Y_{j_{m}^{n}}\right)=\left(\operatorname{ad}\left(F_{k}\right) Y_{i_{m}^{n}}\right) Y_{j_{m}^{n}}+\left(\operatorname{ad}\left(K_{k}\right) Y_{i_{m}^{n}}\right)\left(\operatorname{ad}\left(F_{k}\right) Y_{j_{m}^{n}}\right)=Y_{i_{m}^{n^{\prime}}} Y_{j_{m}^{n^{\prime}}} .
$$

If the condition $\left(\mathrm{P}_{m}^{-}\right)$is satisfied, then we have $\operatorname{ad}\left(F_{k}\right) Y_{i_{m}^{n}}=Y_{i_{m}^{n}}, \operatorname{ad}\left(F_{k}\right) Y_{j_{m}^{n}}=0$. Hence $\operatorname{ad}\left(F_{k}\right)\left(Y_{i_{m}^{n}} Y_{j_{m}^{n}}\right)=Y_{i_{m}^{n^{\prime}}} Y_{j_{m}^{\prime \prime}}$ similarly. Therefore we have ad $\left(F_{k}\right) \psi_{n}=\psi_{n^{\prime}}$.

Next we prove $\operatorname{ad}\left(E_{k}\right) \psi_{n^{\prime}}=\psi_{n}$. We have $\operatorname{ad}\left(E_{k}\right) Y_{i_{m}^{\prime}}=0, \operatorname{ad}\left(E_{k}\right) Y_{j_{m}^{\prime}}=Y_{j_{m}^{n}}$ if the condition ( $\mathrm{P}_{m}^{+}$) is satisfied, and we have $\operatorname{ad}\left(E_{k}\right) Y_{i_{m}^{\prime}}=Y_{i_{m}^{n}}, \operatorname{ad}\left(K_{k}^{-1}\right) Y_{j_{m}^{\prime \prime}}=Y_{j_{m}^{n^{\prime}}}, j_{m}^{n^{\prime}}=j_{m}^{n}$, $\operatorname{ad}\left(E_{k}\right) Y_{j_{m}^{n^{\prime}}}=0$ if the condition $\left(\mathrm{P}_{m}^{-}\right)$is satisfied. Hence we have

$$
\operatorname{ad}\left(E_{k}\right)\left(Y_{i_{m}^{\prime}} Y_{j_{m}^{n^{\prime}}}\right)=\left(\operatorname{ad}\left(E_{k}\right) Y_{i_{m}^{\prime \prime}}\right)\left(\operatorname{ad}\left(K_{k .}^{-1}\right) Y_{j_{m}^{\prime \prime}}\right)+Y_{i n_{m}^{n^{\prime}}}\left(\operatorname{ad}\left(E_{k}\right) Y_{j_{m}^{n^{\prime}}}\right)=Y_{i_{m}^{n}} Y_{j_{m}^{n}}
$$

for $1 \leq m \leq 4$. Therefore we have $\operatorname{ad}\left(E_{k}\right) \psi_{n^{\prime}}=\psi_{n}$.
In other 50 cases, where $\delta_{n}+\alpha_{k} \notin\left\{\delta_{l} \mid 1 \leq l \leq 10\right\}$, we can check $\operatorname{ad}\left(F_{k}\right) \psi_{n}=0$ by a case-by-case consideration as follows.

In the 10 cases where there exists $n^{\prime}$ satisfying $\operatorname{ad}\left(F_{k}\right) \psi_{n^{\prime}}=\psi_{n},((k, n)=(6,2)$, $(5,3),(3,4),(2,5),(4,6),(2,7),(4,7),(3,8),(5,9),(6,10))$, we have $\operatorname{ad}\left(F_{k}\right) Y_{i_{m}^{n}}=$ $\operatorname{ad}\left(F_{k}\right) Y_{j_{m}^{n}}=0$ for $1 \leq m \leq 4$, and hence the assertion is obvious.

In the 8 cases $(k, n)=(5,1),(6,3),(6,4),(6,5),(6,6),(6,7),(6,8),(5,10)$, we have $\operatorname{ad}\left(F_{k}\right) Y_{i_{m}^{n}}=\operatorname{ad}\left(F_{k}\right) Y_{j_{m}^{n}}=0$ for $m=3,4, \operatorname{ad}\left(F_{k}\right) Y_{i_{2}^{n}}=Y_{j_{1}^{n}}, \operatorname{ad}\left(F_{k}\right) Y_{j_{2}^{n}}=0$,
$\operatorname{ad}\left(F_{k}\right) Y_{i_{1}^{n}}=Y_{j_{2}^{n}}, \operatorname{ad}\left(F_{k}\right) Y_{j_{1}^{n}}=0$, and hence $\operatorname{ad}\left(F_{k}\right)\left(Y_{i_{2}^{n}} Y_{j_{2}^{n}}\right)=Y_{j_{1}^{n}} Y_{j_{2}^{n}}, \operatorname{ad}\left(F_{k}\right)\left(Y_{i_{1}^{n}} Y_{j_{1}^{n}}\right)=$ $Y_{j_{2}^{n}} Y_{j_{1}^{n}}$. Thus we have $\operatorname{ad}\left(F_{k}\right) \psi_{n}=q^{2}\left(Y_{j_{1}^{n}} Y_{j_{2}^{n}}-q Y_{j_{2}^{n}} Y_{j_{1}^{n}}\right)=0$ by Proposition 2.3.

In the remaining 32 cases there exists $m^{\prime} \in\{2,3,4\}$ such that $\operatorname{ad}\left(F_{k}\right) Y_{i_{m}^{n}}=0(m \neq$ $\left.m^{\prime}\right), \operatorname{ad}\left(F_{k}\right) Y_{j_{m}^{n}}=0\left(m \neq m^{\prime}-1\right), \operatorname{ad}\left(F_{k}\right) Y_{i_{m^{\prime}}^{\prime}}=Y_{i_{m^{\prime}-1}}, \operatorname{ad}\left(F_{k}\right) Y_{j_{m^{\prime}-1}}=Y_{j_{m^{\prime}}^{n}}, \operatorname{ad}\left(K_{k}\right) Y_{i_{m^{\prime}-1}}=$
 $\operatorname{ad}\left(F_{k}\right) \psi_{n}=q^{4-m^{\prime}}\left(1-q q^{-1}\right) \boldsymbol{Y}_{i_{m^{\prime}-1}^{\prime}} Y_{j_{m^{\prime}}^{\prime \prime}}=0$.

The weight $\beta_{i_{m}^{n}}+\beta_{j_{m}^{n}}$ does not depend on $m$. Hence we have $\operatorname{ad}\left(K_{k}\right) \psi_{n}=q^{-\left(\delta_{n}, \alpha_{k}\right)} \psi_{n}$ where $\delta_{n}=\beta_{i_{m}^{n}}+\beta_{j_{m}}$.

Finally we show $\operatorname{ad}\left(E_{k}\right) \psi_{n}=0$ if $\delta_{n}-\alpha_{k} \notin\left\{\delta_{l} \mid 1 \leq l \leq 10\right\}$. We can check $\operatorname{ad}\left(E_{k}\right) \psi_{1}=0$ for any $k=2,3, \ldots, 6$ directly. It follows that $\sum_{n=1}^{10} \mathbb{C}(q) \psi_{n}=U_{q}\left(\mathfrak{l}_{I}\right) \psi_{1}$ and hence $\sum_{n=1}^{10} \mathbb{C}(q) \psi_{n}$ is an ad $U_{q}\left(l_{l}\right)$-stable subspace with weights in $\left\{-\delta_{l} \mid 1 \leq l \leq\right.$ $10\}$. Therefore we have $\operatorname{ad}\left(E_{k}\right) \psi_{n}=0$ if $\delta_{n}-\alpha_{k} \notin\left\{\delta_{l} \mid 1 \leq l \leq 10\right\}$.

Proposition 2.6. $\sum_{n=1}^{10} \mathbb{C}(q) \psi_{n}$ is an irreducible highest weight $U_{q}\left(\mathfrak{l}_{I}\right)$-module with highest weight vector $\psi_{1}$.

Proof. By Lemma $2.5 \sum_{n=1}^{10} \mathbb{C}(q) \psi_{n}$ is a finite dimensional $U_{q}\left(\mathfrak{l}_{l}\right)$-submodule generated by a highest weight vector $\psi_{1}$ with highest weight $-\delta_{1}$. Thus it is irreducible.

By [4] and Proposition 2.6 we obtain the following:
Theorem 2.7. A quantum analogue of the defining ideal $J_{C_{0}}$ of the closure of the non-trivial non-open orbit $C_{0}$ is given by the two-sided ideal of $A_{q}$ generated by $\left\{\psi_{n} \mid 1 \leq n \leq 10\right\}$.

## 3. Case of type $\boldsymbol{E}_{7}$

Let $\mathfrak{g}$ be a simple Lie algebra of type $E_{7}$. We shall use the labelling of the vertices of the Dynkin diagram 1. Hence we have $I_{0}=\{1,2,3,4,5,6,7\}$. Set $I=$ $\{2,3,4,5,6,7\}$. In this case we have $\mathfrak{n}_{I}^{+} \neq\{0\},\left[\mathfrak{n}_{I}^{+}, \mathfrak{n}_{I}^{+}\right]=\{0\}$. Then $\mathfrak{l}_{I}$ is isomorphic to $\mathbb{C} \oplus \mathfrak{g}_{E_{6}}$, where $\mathfrak{g}_{E_{6}}$ is a Lie algebra of type $E_{6}$ over $\mathbb{C}$, and $\mathfrak{n}_{I}^{+}$is a 27 -dimensional irreducible prehomogeneous vector space. There are four $L_{I}$-orbits $\{0\}, C_{1}, C_{2}, O$ on $\mathfrak{n}_{I}^{+}$satisfying $\{0\} \subset \overline{C_{1}} \subset \overline{C_{2}} \subset \bar{O}$. Let $J_{C_{1}} \subset \mathbb{C}\left[\mathfrak{n}_{I}^{+}\right]$be the defining ideal of the closure of $C_{1}$, and let $J_{C_{1}}^{0}$ denote the subspace of $J_{C_{1}}$ consisting of the polynomials in $J_{C_{1}}$ with homogeneous degree 2 . Then $J_{C_{1}}^{0}$ is a 27 -dimensional irreducible $\mathfrak{l}_{I}$-module, and it generates the ideal $J_{C_{1}}$. Let $J_{C_{2}} \subset \mathbb{C}\left[\mathfrak{n}_{I}^{+}\right]$be the defining ideal of the closure of $C_{2}$, and let $J_{C_{2}}^{0}$ denote the subspace of $J_{C_{2}}$ consisting of the polynomials in $J_{C_{2}}$ with homogeneous degree 3 . Then $J_{C_{2}}^{0}$ is a one-dimensional irreducible $\mathfrak{l}_{I}$-module generated by the irreducible relative invariant, and it generates the ideal $J_{C_{2}}$.

We fix a reduced expression

```
w
```

of $w_{I} w_{0}$ and define the elements $Y_{i}(i \in \Lambda=\{1,2, \ldots, 27\})$ as in Section 1 .
Set $I_{0}^{\prime}=\{1,2,3,4,5,6\}, I^{\prime}=\{2,3,4,5,6\}, \Lambda^{\prime}=\{1,2, \ldots, 10\}$. Then $\left\{\alpha_{i}\right\}_{i \in I_{0}^{\prime}}$ is a set of simple roots of type $D_{6}$. Let $\mathfrak{g}^{\prime}$ be the simple subalgebra of $\mathfrak{g}$ corresponding to $I_{0}^{\prime}$. We choose a reduced expression $w_{I^{\prime}} w_{I_{0}^{\prime}}=s_{1} s_{2} s_{3} s_{4} s_{5} s_{6} s_{4} s_{3} s_{2} s_{1}$ of $w_{I^{\prime}} w_{I_{0}^{\prime}}$. The elements $Y_{i}\left(i \in \Lambda^{\prime}\right)$ can be computed inside $U_{q}\left(\mathfrak{g}^{\prime}\right)$.

Let $\beta_{j}=\sum_{i \in I_{0}} m_{i}^{j} \alpha_{i}$ and set $\mathbf{m}^{j}=\left(m_{1}^{j}, \ldots, m_{7}^{j}\right)$ for $j \in \Lambda$. Then we have

$$
\begin{array}{lll}
\mathbf{m}^{1}=(1,0,0,0,0,0,0), & \mathbf{m}^{2}=(1,1,0,0,0,0,0), & \mathbf{m}^{3}=(1,1,1,0,0,0,0), \\
\mathbf{m}^{4}=(1,1,1,1,0,0,0), & \mathbf{m}^{5}=(1,1,1,1,1,0,0), & \mathbf{m}^{6}=(1,1,1,1,0,1,0), \\
\mathbf{m}^{7}=(1,1,1,1,1,1,0), & \mathbf{m}^{8}=(1,1,1,2,1,1,0), & \mathbf{m}^{9}=(1,1,2,2,1,1,0), \\
\mathbf{m}^{10}=(1,2,2,2,1,1,0), & \mathbf{m}^{11}=(1,1,1,1,0,1,1), & \mathbf{m}^{12}=(1,1,1,1,1,1,1), \\
\mathbf{m}^{13}=(1,1,1,2,1,1,1), & \mathbf{m}^{14}=(1,1,2,2,1,1,1), & \mathbf{m}^{15}=(1,1,1,2,1,2,1), \\
\mathbf{m}^{16}=(1,1,2,2,1,2,1), & \mathbf{m}^{17}=(1,1,2,3,1,2,1), & \mathbf{m}^{18}=(1,1,2,3,2,2,1), \\
\mathbf{m}^{19}=(1,2,2,2,1,1,1), & \mathbf{m}^{20}=(1,2,2,2,1,2,1), & \mathbf{m}^{21}=(1,2,2,3,1,2,1), \\
\mathbf{m}^{22}=(1,2,2,3,2,2,1), & \mathbf{m}^{23}=(1,2,3,3,1,2,1), & \mathbf{m}^{24}=(1,2,3,3,2,2,1), \\
\mathbf{m}^{25}=(1,2,3,4,2,2,1), & \mathbf{m}^{26}=(1,2,3,4,2,3,1), & \mathbf{m}^{27}=(1,2,3,4,2,3,2) .
\end{array}
$$

If $\left(\beta_{j}, \alpha_{k}\right)=-1$ for $j \in \Lambda$ and $k \in I$, then $s_{k}\left(\beta_{j}\right)=\beta_{j}+\alpha_{k} \in \Delta^{+} \backslash \Delta_{I}$ and there exists $l \in \Lambda$ satisfying $\beta_{j}+\alpha_{k}=\beta_{l}$. Conversely if $\beta_{j}, \beta_{l} \in \Delta^{+} \backslash \Delta_{I}$ satisfying $\beta_{l}-\beta_{j}=\alpha_{k}(k \in I)$, then we have $\left(\beta_{j}, \alpha_{k}\right)=-1, s_{k}\left(\beta_{j}\right)=\beta_{l}$.

For $k \in I, j \in \Lambda$, we have $\beta_{j}-2 \alpha_{k}, \beta_{j}+2 \alpha_{k} \notin \Delta^{+} \backslash \Delta_{I}$.
Set

$$
\mathcal{B}=\left\{(k, j, l) \in I \times \Lambda \times \Lambda \mid \beta_{j}+\alpha_{k}=\beta_{l}\right\} .
$$

We have
$\mathcal{B}=\{(2,1,2),(3,2,3),(4,3,4),(5,4,5),(6,4,6),(6,5,7),(5,6,7),(4,7,8),(3,8,9)$, $(2,9,10),(7,6,11),(7,7,12),(7,8,13),(7,9,14),(7,10,19),(5,11,12)$,
$(4,12,13),(3,13,14),(6,13,15),(6,14,16),(3,15,16),(4,16,17),(5,17,18)$,
$(2,14,19),(2,16,20),(2,17,21),(2,18,22),(6,19,20),(4,20,21),(5,21,22)$,
$(3,21,23),(3,22,24),(5,23,24),(4,24,25),(6,25,26),(7,26,27)\}$.
In particular, we have $|\mathcal{B}|=36$.
Lemma 3.1. Let $\beta, \beta^{\prime} \in \Delta^{+} \backslash \Delta_{I}$ satisfying $\beta+\alpha_{k}=\beta^{\prime}(k \in I)$. Then we can choose a reduced expression $w_{I} w_{0}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{27}}$ and $p \in \Lambda$ satisfying

$$
\begin{aligned}
& \beta=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}}\left(\alpha_{i_{p}}\right), \quad \beta^{\prime}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}} s_{i_{p}}\left(\alpha_{i_{p+1}}\right), \quad\left(\alpha_{i_{p}}, \alpha_{i_{p+1}}\right)=-1, \\
& \alpha_{k}=s_{i_{1}} s_{i_{2}} \cdots s_{i_{p-1}}\left(\alpha_{i_{p+1}}\right) .
\end{aligned}
$$

Proof. The 21 triplets $(k, j, l)$ in $\mathcal{B}$ satisfy $l=j+1,\left(\alpha_{i_{j}}, \alpha_{i_{j+1}}\right)=-1$. Therefore it is sufficient to deal with the remaining 15 cases. In the cases $(k, j, l)=(6,4,6)$, $(6,5,7),(6,13,15),(6,14,16),(3,21,23),(3,22,24)$, we can take

```
w
```

with $p=4,6,13,15,21,23$, and in the cases $(k, j, l)=(7,6,11),(7,7,12),(7,8,13)$, $(7,9,14),(7,10,19)$, we can take

$$
w_{I} w_{0}=s_{1} s_{2} s_{3} s_{4} s_{5} s_{6} s_{7} s_{4} s_{6} s_{3} s_{4} s_{2} s_{3} s_{1} s_{2} s_{5} s_{4} s_{6} s_{7} s_{3} s_{4} s_{6} s_{5} s_{4} s_{3} s_{2} s_{1}
$$

with $p=6,8,10,12,14$, and in the cases $(k, j, l)=(2,14,19),(2,16,20),(2,17,21)$, $(2,18,22)$, we can take

```
w
```

with $p=15,17,19,21$.

We can show the following similarly to the case $E_{6}$. We omit the details.

Lemma 3.2. For $k \in I, j \in \Lambda$, we have

$$
\begin{aligned}
\operatorname{ad}\left(F_{k}\right) Y_{j} & = \begin{cases}Y_{l} & \text { if there exists }(k, j, l) \in \mathcal{B}, \\
0 & \text { otherwise },\end{cases} \\
\operatorname{ad}\left(E_{k}\right) Y_{j} & = \begin{cases}Y_{l} & \text { if there exists }(k, l, j) \in \mathcal{B}, \\
0 & \text { otherwise. }\end{cases}
\end{aligned}
$$

The $U_{q}\left(l_{l}\right)$-module $\bigoplus_{j \in \Lambda} \mathbb{C}(q) Y_{j}$ is an irreducible highest weight module with highest weight vector $Y_{1}$ and lowest weight vector $Y_{27}$. Hence, for any $1 \leq m \leq 26$, there exists a sequence $\left(\left(k_{1}, n_{1}^{\prime}, n_{1}\right), \ldots,\left(k_{s}, n_{s}^{\prime}, n_{s}\right)\right)$ of $\mathcal{B}$ satisfying $n_{1}=27, n_{s}^{\prime}=m$, $n_{j}^{\prime}=n_{j+1}(1 \leq j \leq s-1)$.

Next we shall consider relations among the elements $Y_{i}$. We can write

$$
Y_{i} Y_{j}=\sum_{\substack{s \leq \leq \\ \beta_{i}+\beta_{j}=\beta_{s}+\beta_{t}}} a_{s, t}^{i, j} Y_{s} Y_{t} \quad\left(a_{s, t}^{i, j} \in \mathbb{C}(q)\right)
$$

for $i>j$ (see [4]). Hence if $\beta_{i}+\beta_{j}$ does not have another decomposition $\beta+\beta^{\prime}\left(\beta, \beta^{\prime} \in\right.$ $\Delta^{+} \backslash \Delta_{I}, \beta_{i}+\beta_{j}=\beta+\beta^{\prime}$ ) then we have $Y_{i} Y_{j}=a_{i, j} Y_{j} Y_{i}$ for some $a_{i, j} \in \mathbb{C}(q)$. Set $\delta=2 \varpi_{1}=3 \alpha_{1}+4 \alpha_{2}+5 \alpha_{3}+6 \alpha_{4}+3 \alpha_{5}+4 \alpha_{6}+2 \alpha_{7}$, where $\varpi_{1}$ is the fundamental weight corresponding to $\alpha_{1}$. We denote a set of weights of the 27-dimensional irreducible highest weight $\mathfrak{l}_{I}$-module $J_{C_{1}}^{0}$ with highest weight $-\beta_{1}-\beta_{10}$ by $\Gamma$. Set $\gamma_{n}=\delta-\beta_{n}(n \in \Lambda)$, and we have $\Gamma=\left\{-\gamma_{n} \mid n \in \Lambda\right\}$. For $\beta, \beta^{\prime} \in \Delta^{+} \backslash \Delta_{I}$ a weight $\beta+\beta^{\prime}$ has another decomposition if and only if we have $-\left(\beta+\beta^{\prime}\right) \in \Gamma$. For each $n \in \Lambda$ there
exist exactly five pairs $(i, j) \in \Lambda^{2}$ such that $i<j, \beta_{i}+\beta_{j}=\gamma_{n}$. We denote them by $\left(i_{1}^{n}, j_{1}^{n}\right),\left(i_{2}^{n}, j_{2}^{n}\right),\left(i_{3}^{n}, j_{3}^{n}\right),\left(i_{4}^{n}, j_{4}^{n}\right),\left(i_{5}^{n}, j_{5}^{n}\right) \in \Lambda^{2}$ where $i_{5}^{n}<i_{4}^{n}<i_{3}^{n}<i_{2}^{n}<i_{1}^{n}$, $j_{1}^{n}<j_{2}^{n}<j_{3}^{n}<j_{4}^{n}<j_{5}^{n}$, and $i_{1}^{n}, j_{1}^{n}$ satisfy the following condition ( $\mathrm{P}_{1}^{+}$) or ( $\mathrm{P}_{1}^{-}$). Set $\mathbf{B}(n)=\left(i_{5}^{n}, i_{4}^{n}, i_{3}^{n}, i_{2}^{n}, i_{1}^{n}, j_{1}^{n}, j_{2}^{n}, j_{3}^{n}, j_{4}^{n}, j_{5}^{n}\right) \in \Lambda^{10}(n \in \Lambda)$. Then we have $\mathbf{B}(1)=(10,19,20,21,23,22,24,25,26,27), \mathbf{B}(2)=(9,14,16,17,23,18,24,25,26,27)$, $\mathbf{B}(3)=(8,13,15,17,21,18,22,25,26,27), \quad \mathbf{B}(4)=(7,12,15,16,20,18,22,24,26,27)$, $\mathbf{B}(5)=(6,11,15,16,20,17,21,23,26,27), \quad \mathbf{B}(6)=(5,12,13,14,19,18,22,24,25,27)$, $\mathbf{B}(7)=(4,11,13,14,19,17,21,23,25,27), \quad \mathbf{B}(8)=(3,11,12,14,19,16,20,23,24,27)$, $\mathbf{B}(9)=(2,11,12,13,19,15,20,21,22,27), \quad \mathbf{B}(10)=(1,11,12,13,14,15,16,17,18,27)$, $\mathbf{B}(11)=(5,7,8,9,10,18,22,24,25,26), \quad \mathbf{B}(12)=(4,6,8,9,10,17,21,23,25,26)$,
$\mathbf{B}(13)=(3,6,7,9,10,16,20,23,24,26), \quad \mathbf{B}(14)=(2,6,7,8,10,15,20,21,22,26)$,
$\mathbf{B}(15)=(3,4,5,9,10,14,19,23,24,25), \quad \mathbf{B}(16)=(2,4,5,8,10,13,19,21,22,25)$,
$\mathbf{B}(17)=(2,3,5,7,10,12,19,20,22,24), \quad \mathbf{B}(18)=(2,3,4,6,10,11,19,20,21,23)$,
$\mathbf{B}(19)=(1,6,7,8,9,15,16,17,18,26), \quad B(20)=(1,4,5,8,9,13,14,17,18,25)$,
$\mathbf{B}(21)=(1,3,5,7,9,12,14,16,18,24), \quad \mathbf{B}(22)=(1,3,4,6,9,11,14,16,17,23)$,
$\mathbf{B}(23)=(1,2,5,7,8,12,13,15,18,22), \quad \mathbf{B}(24)=(1,2,4,6,8,11,13,15,17,21)$,
$\mathbf{B}(25)=(1,2,3,6,7,11,12,15,16,20), \quad \mathbf{B}(26)=(1,2,3,4,5,11,12,13,14,19)$, $\mathbf{B}(27)=(1,2,3,4,5,6,7,8,9,10)$.

For $n \in \Lambda$ we denote the set $\left\{i_{5}^{n}, i_{4}^{n}, i_{3}^{n}, i_{2}^{n}, i_{1}^{n}, j_{1}^{n}, j_{2}^{n}, j_{3}^{n}, j_{4}^{n}, j_{5}^{n}\right\}$ by $|\mathbf{B}(n)|$. For any $i, j \in \Lambda$ there exists $n \in \Lambda$ satisfying $i, j \in|\mathbf{B}(n)|$.

For $\left(k, n^{\prime}, n\right) \in \mathcal{B}$ and $m \in\{1,2,3,4,5\}$, we have either $\left(\mathrm{P}_{m}^{+}\right) \quad\left(\beta_{i_{m}^{n}}, \alpha_{k}\right)=0, i_{m}^{n^{\prime}}=i_{m}^{n},\left(\beta_{j_{m}^{n}}, \alpha_{k}\right)=-1, \beta_{j_{m}^{\prime}}=\beta_{j_{m}^{n}}+\alpha_{k}$ or
( $\mathrm{P}_{m}^{-}$) $\quad\left(\beta_{i_{m}^{n}}, \alpha_{k}\right)=-1, \beta_{i_{m}^{n^{\prime}}}=\beta_{i_{m}^{n}}+\alpha_{k},\left(\beta_{j_{m}^{n}}, \alpha_{k}\right)=0, j_{m}^{n^{\prime}}=j_{m}^{n}$.
Proposition 3.3. For any $i, j \in \Lambda$ satisfying $i<j$, we have
(Q7)

$$
Y_{i} Y_{j}= \begin{cases}Y_{j} Y_{i} & \text { if there exists } n \in \Lambda \text { such that }\{i, j\}=\left\{i_{1}^{n}, j_{1}^{n}\right\}, \\ Y_{j_{2}^{n}} Y_{i_{2}^{n}}+\left(q-q^{-1}\right) Y_{i_{1}^{n}} Y_{j_{1}^{n}} \\ Y_{j_{m}^{n}} Y_{i_{m}^{n}}+q Y_{j_{m-1}^{n}} Y_{i_{m-1}^{n}}-q^{-1} Y_{i_{m-1}^{n}} Y_{j_{m-1}^{n}}^{n}, 4 \text { such that } i=i_{2}^{n}, j=j_{2}^{n}, \\ \text { if there exist } n \in \Lambda, m \in\{3,4,5\} \text { such that } i=i_{m}^{n}, j=j_{m}^{n}, \\ q Y_{j} Y_{i} & \text { otherwise. }\end{cases}
$$

Proof. Since there exists $n \in \Lambda$ satisfying $i, j \in|\mathbf{B}(n)|$ for any $i, j \in \Lambda$, it is
sufficient to show

$$
\left\{\begin{array}{l}
Y_{i_{1}^{n}} Y_{j_{1}^{n}}=Y_{j_{1}^{n}} Y_{i_{1}^{n}}  \tag{Rn}\\
Y_{i_{m}^{n}} Y_{j_{m}^{n}}=Y_{j_{m}^{n}} Y_{i_{m}^{n}}+q Y_{j_{m-1}^{n}} Y_{i_{m-1}^{m}}-q^{-1} Y_{i_{m-1}^{m}} Y_{j_{m-1}^{n}}^{n}(2 \leq m \leq 5) \quad \text { (Rn,1) } \\
Y_{l_{1}} Y_{l_{2}}=q Y_{l_{2}} Y_{l_{1}} \\
\quad\left(l_{1}, l_{2} \in|\mathbf{B}(n)|, l_{1}<l_{2},\left\{l_{1}, l_{2}\right\} \neq\left\{i_{m}^{n}, j_{m}^{n}\right\}(1 \leq m \leq 5)\right) \quad(\mathrm{R} n, 3)
\end{array}\right.
$$

for $n \in \Lambda$ and $1 \leq m \leq 5$.
When $n=27$, the elements $Y_{i}(1 \leq i \leq 10)$ satisfy the same relations as those for type $D_{6}$, and hence relations (R27) hold.

Since there exists a sequence $\left(\left(k_{1}, n_{1}^{\prime}, n_{1}\right), \ldots,\left(k_{s}, n_{s}^{\prime}, n_{s}\right)\right)$ of $\mathcal{B}$ satisfying $n_{1}=$ 27, $n_{s}^{\prime}=m, n_{j}^{\prime}=n_{j+1}(1 \leq j \leq s-1)$ for any $1 \leq m \leq 26$, it is sufficient to show ( $\mathrm{R} n^{\prime}$ ) for $\left(k, n^{\prime}, n\right) \in \mathcal{B}$ assuming ( $\mathrm{R} n$ ). This is proved similarly to Proposition 2.3. Details are omitted.

By [4] and Proposition 3.3 we obtain the following:
Theorem 3.4. The formulas (Q7) give fundamental relations for the generator system $\left\{Y_{i}\right\}_{i \in \Lambda}$ of the algebra $A_{q}=U_{q}\left(\mathfrak{n}_{I}^{-}\right)$.

We shall construct a quantum deformation of the lowest degree part $J_{C_{1}}^{0}$ of the defining ideal $J_{C_{1}}$ and we shall give canonical generators of a quantum deformation of $J_{C_{1}}$.

Set

$$
\psi_{n}=Y_{i_{5}} Y_{j_{5}^{n}}-q Y_{i_{4}^{n}} Y_{j_{4}^{n}}+q^{2} Y_{i_{3}^{n}} Y_{j_{3}^{n}}-q^{3} Y_{i_{2}^{n}} Y_{j_{2}^{n}}+q^{4} Y_{i_{1}^{n}} Y_{i_{1}^{n}},
$$

for $n \in \Lambda$, where $\mathbf{B}(n)=\left(i_{5}^{n}, i_{4}^{n}, i_{3}^{n}, i_{2}^{n}, i_{1}^{n}, j_{1}^{n}, j_{2}^{n}, j_{3}^{n}, j_{4}^{n}, j_{5}^{n}\right)$. Using the formulas ( $\mathrm{R} n, 1$ ), ( $\mathrm{R} n, 2$ ), we can write

$$
\psi_{n}=Y_{j_{5}^{n}} Y_{i_{5}^{n}}-q^{-1} Y_{j_{4}^{n}} Y_{i_{4}^{n}}+q^{-2} Y_{j_{3}^{n}} Y_{i_{3}^{n}}-q^{-3} Y_{j_{2}^{n}} Y_{i_{2}^{n}}+q^{-4} Y_{j_{1}^{n}} Y_{i_{1}^{n}} .
$$

Similarly to Lemma 2.5 and Proposition 2.6 we can show the following:
Lemma 3.5. We have

$$
\begin{aligned}
\operatorname{ad}\left(F_{k}\right) \psi_{n} & = \begin{cases}\psi_{n^{\prime}} & \text { if there exists }\left(k, n^{\prime}, n\right) \in \mathcal{B}, \\
0 & \text { otherwise },\end{cases} \\
\operatorname{ad}\left(E_{k}\right) \psi_{n} & = \begin{cases}\psi_{n^{\prime}} & \text { if there exists }\left(k, n, n^{\prime}\right) \in \mathcal{B} \\
0 & \text { otherwise }\end{cases}
\end{aligned}
$$

for $k \in I$, and

$$
\operatorname{ad}\left(K_{k}\right) \psi_{n}=q^{-\left(\gamma_{n}, \alpha_{k}\right)} \psi_{n}
$$

for $k \in I_{0}$.
Proposition 3.6. $\sum_{n \in \Lambda} \mathbb{C}(q) \psi_{n}$ is an irreducible highest weight $U_{q}\left(\mathfrak{l}_{I}\right)$-module with highest weight vector $\psi_{27}$.

By [4] and Proposition 3.6 we obtain the following:
Theorem 3.7. A quantum deformation of the defining ideal $J_{C_{1}}$ of the closure of the non-open orbit $C_{1}$ is given by the two-sided ideal of $A_{q}$ generated by $\left\{\psi_{n} \mid n \in\right.$ $\Lambda$ \}.

Set

$$
\varphi=\sum_{n \in \Lambda}(-q)^{\left|\beta_{n}\right|-1} Y_{n} \psi_{n}
$$

where $|\beta|=\sum_{i \in I_{0}} m_{i}\left(\beta=\sum_{i \in I_{0}} m_{i} \alpha_{i}\right)$.
Proposition 3.8. $\mathbb{C}(q) \varphi$ is a one-dimensional $U_{q}\left(\mathrm{l}_{I}\right)$-module.
Proof. By Proposition 3.3 we can check that the coefficient $a_{1,10,27}$ of $Y_{1} Y_{10} Y_{27}$ in $\varphi=\sum_{i<j<k} a_{i j k} Y_{i} Y_{j} Y_{k}$ is $1+q^{8}+q^{16}$. Therefore we have $\varphi \neq 0$.

Let $\left(k, n, n^{\prime}\right) \in \mathcal{B}$. Then we have $\left|\beta_{n^{\prime}}\right|=\left|\beta_{n}\right|+1, \operatorname{ad}\left(F_{k}\right) Y_{n}=Y_{n^{\prime}}, \operatorname{ad}\left(F_{k}\right) Y_{n^{\prime}}=0$, $\operatorname{ad}\left(F_{k}\right) \psi_{n^{\prime}}=\psi_{n}, \operatorname{ad}\left(F_{k}\right) \psi_{n}=0,\left(\beta_{n^{\prime}}, \alpha_{k}\right)=1$. Hence $\operatorname{ad}\left(F_{k}\right)\left(Y_{n} \psi_{n}-q Y_{n^{\prime}} \psi_{n^{\prime}}\right)=Y_{n^{\prime}} \psi_{n}-$ $q q^{-1} Y_{n^{\prime}} \psi_{n}=0$. Therefore we have $\operatorname{ad}\left(F_{k}\right) \varphi=0$ for any $k \in I$, and similarly we have $\operatorname{ad}\left(E_{k}\right) \varphi=0$ for any $k \in I$. Since $\gamma_{n}+\beta_{n}=\delta$ for any $n \in \Lambda$, we have $\operatorname{ad}\left(K_{k}\right) \varphi=$ $q^{-\left(\delta, \alpha_{k}\right)} \varphi$ for any $k \in I_{0}$. In particular, we have $\operatorname{ad}\left(K_{k}\right) \varphi=\varphi$ for any $k \in I$, and $\operatorname{ad}\left(K_{1}\right) \varphi=q^{-2} \varphi$.

The element $\varphi$ is a quantum deformation of the irreducible relative invariant on the prehomogeneous vector space.

Theorem 3.9. A quantum deformation of the defining ideal $J_{C_{2}}$ of the closure of the non-open orbit $C_{2}$ is given by the two-sided ideal of $A_{q}$ generated by $\varphi$.
