# ON A MORELLI TYPE EXPRESSION OF COHOMOLOGY CLASSES OF TORUS ORBIFOLDS 

Akio HATTORI

(Received August 19, 2013)

#### Abstract

Let $X$ be a complete toric variety of dimension $n$ and $\Delta$ the fan in a lattice $N$ associated to $X$. For each cone $\sigma$ of $\Delta$ there corresponds an orbit closure $V(\sigma)$ of the action of complex torus on $X$. The homology classes $\{[V(\sigma)] \mid \operatorname{dim} \sigma=k\}$ form a set of specified generators of $H_{n-k}(X, \mathbb{Q})$. Then any $x \in H_{n-k}(X, \mathbb{Q})$ can be written in the form $$
x=\sum_{\sigma \in \Delta_{X}, \operatorname{dim} \sigma=k} \mu(x, \sigma)[V(\sigma)] .
$$

A question occurs whether there is some canonical way to express $\mu(x, \sigma)$. Morelli [12] gave an answer when $X$ is non-singular and at least for $x=\mathcal{T}_{n-k}(X)$ the Todd class of $X$. However his answer takes coefficients in the field of rational functions of degree 0 on the Grassmann manifold $G_{n-k+1}\left(N_{\mathbb{Q}}\right)$ of $(n-k+1)$-planes in $N_{\mathbb{Q}}$. His proof uses Baum-Bott's residue formula for holomorphic foliations applied to the action of complex torus on $X$

On the other hand there appeared several attempts for generalizing non-singular toric varieties in topological contexts [4, 10, 7, 11, 9, 2]. Such generalized manifolds of dimension $2 n$ acted on by a compact $n$ dimensional torus $T$ are called by the names quasi-toric manifolds, torus manifolds, toric manifolds, toric origami manifolds, topological toric manifolds and so on. Similarly torus orbifold can be considered. To a torus orbifold $X$ a simplicial set $\Delta_{X}$ called multi-fan of $X$ is associated. A question occurs whether a similar expression to Morelli's formula holds for torus orbifolds. It will be shown the answer is yes in this case too at least when the rational cohomology ring $H^{*}(X)_{\mathbb{Q}}$ is generated by $H^{2}(X)_{\mathbb{Q}}$. Under this assumption the equivariant cohomology ring with rational coefficients $H_{T}^{*}(X, \mathbb{Q})$ is isomorphic to $H_{T}^{*}\left(\Delta_{X}, \mathbb{Q}\right)$, the face ring of the multi-fan $\Delta_{X}$, and the proof is carried out on $H_{T}^{*}\left(\Delta_{X}, \mathbb{Q}\right)$ by using completely combinatorial terms.

## 1. Introduction

Let $X$ be a complete toric variety of dimension $n$ and $\Delta_{X}$ the fan associated to $X . \Delta_{X}$ is a collection of rational convex cones in $N_{\mathbb{R}}=N \otimes \mathbb{R}$ where $N$ is a lattice of rank $n$. For each $k$-dimensional cone $\sigma$ in $\Delta_{X}$, let $V(\sigma)$ be the corresponding orbit closure of dimension $n-k$ and $[V(\sigma)] \in A_{n-k}(X)$ be its Chow class. Then the Todd

[^0]class $\mathcal{T}_{n-k}(X)$ of $X$ can be written in the form
\[

$$
\begin{equation*}
\mathcal{T}_{n-k}(X)=\sum_{\sigma \in \Delta_{X}, \operatorname{dim} \sigma=k} \mu_{k}(\sigma)[V(\sigma)] \tag{1}
\end{equation*}
$$

\]

However, since the $[V(\sigma)]$ are not linearly independent, the coefficients $\mu_{k}(\sigma) \in \mathbb{Q}$ are not determined uniquely. Danilov [3] asks if $\mu_{k}(\sigma)$ can be chosen so that it depends only on the cone $\sigma$ not depending on a particular fan in which it lies.

The equality (1) has a close connection with the number $\#(P)$ of lattice points contained in a convex lattice polytope $P$ in $M_{\mathbb{R}}$ where $M$ is the dual lattice of $N$. For a positive integer $v$ the number $\#(\nu P)$ is expanded as a polynomial in $v$ (called Ehrhart polynomial):

$$
\#(v P)=\sum_{k} a_{k}(P) v^{n-k}
$$

A convex lattice polytope $P$ in $M_{\mathbb{R}}$ determines a complete toric variety $X$ and an invariant Cartier divisor $D$ on $X$. There is a one-to-one correspondence between the cells $\{\sigma\}$ of $\Delta_{X}$ and the faces $\left\{P_{\sigma}\right\}$ of $P$. Then the coefficient $a_{k}(P)$ has an expression

$$
\begin{equation*}
a_{k}(P)=\sum_{\operatorname{dim} \sigma=k} \mu_{k}(\sigma) \operatorname{vol} P_{\sigma} \tag{2}
\end{equation*}
$$

with the same $\mu_{k}(\sigma)$ as in (1).
Hereafter we shall use notation $H_{T}^{*}()_{\mathbb{Q}}$ to mean $H_{T}^{*}() \otimes \mathbb{Q}$ and so on.
We shall restrict ourselves to the case where $X$ is non-singular. Put $D_{i}=\left[V\left(\sigma_{i}\right)\right]$ for the one dimensional cone $\sigma_{i}$, and let $x_{i} \in H^{2}(X)$ denote the Poincaré dual of $D_{i}$. The divisor $D$ is written in the form $D=\sum_{i} d_{i} D_{i}$ with positive integers $d_{i}$. Put $\xi=$ $\sum_{i} d_{i} x_{i}$. It is known that

$$
a_{k}(P)=\int_{X} e^{\xi} \mathcal{T}^{k}(X)
$$

and

$$
\operatorname{vol} P_{\sigma}=\int_{X} e^{\xi} x_{\sigma}
$$

where $\mathcal{T}^{k}(X) \in H^{2 k}(X)_{\mathbb{Q}}$ is the $k$-th component of the Todd cohomology class, the Poincaré dual of $\mathcal{T}_{n-k}(X)$, and $x_{\sigma} \in H^{2 k}(X)$ is the Poincaré dual of [ $V(\sigma)$ ]. The cohomology class $x_{\sigma}$ can also be written as $x_{\sigma}=\prod_{j} x_{j}$ where the product runs over such $j$ that $\sigma_{j}$ is an edge of $\sigma$. Then the equality (2) can be rewritten as

$$
\begin{equation*}
\int_{X} e^{\xi} \mathcal{T}^{k}(X)=\sum_{\operatorname{dim} \sigma=k} \mu_{k}(\sigma) \int_{X} e^{\xi} x_{\sigma} \tag{3}
\end{equation*}
$$

The reader is referred to [5] Section 5.3 for details and Note 17 there for references.

In his paper [12] Morelli gave an answer to Danilov's question. Let $\left.\operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)\right)_{0}$ denote the field of rational functions of degree 0 on the Grassmann manifold of $(n-k+1)$-planes in $N_{\mathbb{Q}}$. For a cone $\sigma$ of dimension $k$ in $N_{\mathbb{R}}$ he associates a rational function $\left.\mu_{k}(\sigma) \in \operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)\right)_{0}$. With this $\mu_{k}(\sigma)$, the right hand side of (1) belongs to

$$
\left.\operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)\right)_{0} \otimes_{\mathbb{Q}} A_{n-k}(X)_{\mathbb{Q}}
$$

and the equality (1) means that the rational function with values in $A_{n-k}(X)_{\mathbb{Q}}$ in the right hand side is in fact a constant function equal to $\mathcal{T}_{n-k}(X)$ in $A_{n-k}(X)_{\mathbb{Q}}$. In other words this means that

$$
\sum_{\sigma \in \Delta x, \operatorname{dim} \sigma=k} \mu_{k}(\sigma)(E)[V(\sigma)]=\mathcal{T}_{n-k}(X)
$$

for any generic ( $n-k+1$ )-plane $E$ in $N_{\mathbb{Q}}$.
Morelli gives an explicit formula for $\mu_{k}(\sigma)$ when the toric variety is non-singular using Baum-Bott's residue formula for singular foliations [1] applied to the action of $\left(\mathbb{C}^{*}\right)^{n}$ on $X$. He then shows that the function $\mu_{k}(\sigma)$ is additive with respect to nonsingular subdivisions of the cone $\sigma$. This fact leads to (1) in its general form.

One can ask a similar question about general classes other than the Todd class whether it is possible to define $\left.\mu(x, \sigma) \in \operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)\right)_{0}$ for $x \in A_{n-k}(X)$ in a canonical way to satisfy

$$
\begin{equation*}
x=\sum_{\sigma \in \Delta_{X}, \operatorname{dim} \sigma=k} \mu(x, \sigma)[V(\sigma)] . \tag{4}
\end{equation*}
$$

When $X$ is non-singular, one can expect that $\mu(x, \sigma)$ satisfies a formula analogous to (3)

$$
\begin{equation*}
\int_{X} e^{\xi} x=\sum_{\operatorname{dim} \sigma=k} \mu(x, \sigma) \int_{X} e^{\xi} x_{\sigma} \tag{5}
\end{equation*}
$$

for any cohomology class $\xi=\sum_{i} d_{i} x_{i}$. In this sense the formula does not explicitly refer to convex polytopes. Fulton and Sturmfels [6] used Minkowski weights to describe intersection theory of toric varieties. For complete non-singular varieties or $\mathbb{Q}$-factorial varieties $X$ the Minkowski weight $\gamma_{x}: H^{2(n-k)}(X) \rightarrow \mathbb{Q}$ corresponding to $x \in H^{2 k}(X)$ is defined by $\gamma_{x}(y)=\int_{X} x y$. Thus, if the $d_{i}$ are considered as variables in $\xi$, the formula (5) is considered as describing $\gamma_{x}$ as a linear combination of the Minkowski weights of $\gamma_{x_{\sigma}}$.

On the other hand topological analogues of toric variety were discussed by several authors $[4,10,7,11,9,2]$. Most general one would be torus orbifold [7]. To a torus orbifold $X$ a multi-fan $\Delta_{X}$ is associated. Multi-fan is a generalized notion of fan. Its cohomology reflects the cohomology of the torus orbifold.

The purpose of the present paper is to establish the formula (5) by showing an explicit formula for $\mu(x, \sigma)$ when $X$ is a torus orbifold. Moreover our proof is based on a simple combinatorial argument carried on the associated multi-fan $\Delta_{X}$. Topologically the formula concerns equivariant cohomology classes on torus orbifolds. This would suggest that actions of compact tori equipped with some nice conditions admit topological residue formulas similar to Baum-Bott' formula.

In Section 2 we recall the definition of multi-fans and torus orbifolds together with relevant facts. The definition of $\mu(x, \sigma)$ is given for multi-fans and consequently for torus orbifolds. Theorem 3.1 states that the formula (1) holds for any torus orbifolds. Furthermore Corollary 3.2 ensures that the formula (2) holds for torus orbifolds. Finally Corollary 3.3 states that (4) holds for a torus orbifolds $X$ such that $H^{*}(X)_{\mathbb{Q}}$ is generated by $H^{2}(X)_{\mathbb{Q}}$.

## 2. Multi-fans and torus orbifolds

The notion of multi-fan and multi-polytope were introduced in [10]. In this article we shall be concerned only with simplicial multi-fans. See $[10,7,8]$ for details.

Let $N$ be a lattice of rank $n$. A simplicial multi-fan in $N$ is a triple $\Delta=(\Sigma, C, w)$ where $\Sigma=\bigsqcup_{k=0}^{n} \Sigma^{(k)}$ is an (augmented) simplicial complex, $\Sigma^{(k)}$ being the set of $k-1$ simplices, $C$ is a map from $\Sigma^{(k)}$ into the set of $k$-dimensional strongly convex rational polyhedral cones in the vector space $N_{\mathbb{R}}=N \otimes \mathbb{R}$ for each $k$, and $w$ is a map $\Sigma^{(n)} \rightarrow$ $\mathbb{Z}$. $\Sigma^{(0)}$ consists of a single element $o=$ the empty set. (The definition in [10] and [7] requires additional restriction on $w$.) We assume that any $J \in \Sigma$ is contained in some $I \in \Sigma^{(n)}$ and $\Sigma^{(n)}$ is not empty.

The map $C$ is required to satisfy the following condition; if $J \in \Sigma$ is a face of $I \in \Sigma$, then $C(J)$ is a face of $C(I)$, and for any $I$, the map $C$ restricted on $\Sigma(I)=$ $\{J \in \Sigma \mid J \subset I\}$ is an isomorphism of ordered sets onto the set of faces of $C(I)$. It follows that $C(I)$ is necessarily a simplicial cone and $C(o)=0$. A simplicial fan is considered as a simplicial multi-fan such that the map $C$ on $\Sigma$ is injective and $w \equiv 1$.

For each $K \in \Sigma$ we set

$$
\Sigma_{K}=\{J \in \Sigma \mid K \subset J\}
$$

It inherits the partial ordering from $\Sigma$ and becomes a simplicial set where $\Sigma_{K}^{(j)} \subset$ $\Sigma^{(j+|K|)} . K$ is the unique element in $\Sigma_{K}^{(0)}$. Let $N_{K}$ be the minimal primitive sublattice of $N$ containing $N \cap C(K)$, and $N^{K}$ the quotient lattice of $N$ by $N_{K}$. For $J \in \Sigma_{K}$ we define $C_{K}(J)$ to be the cone $C(J)$ projected on $N^{K} \otimes \mathbb{R}$. We define a function

$$
w: \Sigma_{K}^{(n-|K|)} \subset \Sigma^{(n)} \rightarrow \mathbb{Z}
$$

to be the restrictions of $w$ to $\Sigma_{K}^{(n-|K|)}$. The triple $\Delta_{K}=\left(\Sigma_{K}, C_{K}, w\right)$ is a multi-fan in $N^{K}$ and is called the projected multi-fan with respect to $K \in \Sigma$. For $K=o$, the projected multi-fan $\Delta_{o}$ is nothing but $\Delta$ itself.

A vector $v \in N_{\mathbb{R}}$ will be called generic if $v$ does not lie on any linear subspace spanned by a cone in $C(\Sigma)$ of dimension less than $n$. For a generic vector $v$ we set $d_{v}=\sum_{v \in C(I)} w(I)$, where the sum is understood to be zero if there are no such $I$.

Definition. A simplicial multi-fan $\Delta=(\Sigma, C, w)$ is called pre-complete if the integer $d_{v}$ is independent of generic vectors $v$. In this case this integer will be called the degree of $\Delta$ and will be denoted by $\operatorname{deg}(\Delta)$. It is also called the Todd genus of $\Delta$ and is denoted by $\operatorname{Td}[\Delta]$. A pre-complete multi-fan $\Delta$ is said to be complete if the projected multi-fan $\Delta_{K}$ is pre-complete for every $K \in \Sigma$.

A multi-fan is complete if and only if the projected multi-fan $\Delta_{J}$ is pre-complete for every $J \in \Sigma^{(n-1)}$.

Like a toric variety gives rise to a fan, a torus orbifold gives rise to a complete simplicial multi-fan, though this correspondence is not one to one. A torus orbifold is a closed oriented orbifold with an effective action (in the sense of orbifold action) of a compact torus of half the dimension of the orbifold with non-empty fixed point set and with some additional conditions on the orientations of certain type of suborbifolds (precise statement will be given later. See [13] for terminologies concerning orbifolds, and [7] for those of torus orbifolds). Cobordism invariants of torus orbifolds are encoded in the associated multi-fans.

Let $X$ be a torus orbifold. A connected component of the fix point set of a subcircle of the torus $T$ is a suborbifold. A suborbifold of this type which has codimension two and contains at least one fixed point of the action of $T$ is called characteristic suborbifold. By the orientation convention included in the definition of torus orbifold, a characteristic suborbifold is equipped with a fixed orientation.

In the following, characteristic suborbifolds will be denoted by $X_{i}$. In the multi-fan $\Delta(X)=(\Sigma(X), C(X), w(X))$ the simplicial complex $\Sigma(X)$ is given by

$$
\Sigma^{(k)}(X)=\left\{I \mid \# I=k+1,\left(\bigcap_{i \in I} X_{i}\right)^{T} \neq \emptyset\right\} .
$$

Let $S_{i}$ be the circle that fixes the points of $X_{i}$. Take a point $x$ in $X_{i}$. Take an orbifold chart ( $U_{x}, V_{x}, H_{x}, p_{x}$ ) around $x$ in which $U_{x}$ is invariant under the action of $S_{i}$ and $V_{x}$ is an Euclidean ball on which $H_{x}$ acts linearly and the projection $p_{x}: V_{x} \rightarrow U_{x}$ identifies $V_{x} / H_{x}$ with $U_{x}$. Then there exist a covering group $\tilde{S}_{i}$ of $S_{i}$ and a lifting of the action of $S_{i}$ to the action of $\tilde{S}_{i}$ on $V_{x}$ (exactly its tangent space). Hereafter we shall always take the minimal covering with the above property.

If $x$ is a fixed point of the action of $T, U_{x}$ can be taken invariant under the action of $T$ and such that $p_{x}^{-1}(x)$ is a single point. Furthermore if $x$ is in a characteristic suborbifold $X_{i}$, then the vector space $V_{x}$ decomposes into a direct sum $V_{x}=V_{i}+$ $V_{i}^{\perp}$ where $V_{i}^{\perp}$ is tangent to $p_{x}^{-1}\left(U_{x} \cap X_{i}\right)$ and $V_{i}$ is normal to the tangent space of
$p_{x}^{-1}\left(U_{x} \cap X_{i}\right)$ at $p_{x}^{-1}(x)$ and is endowed with an invariant complex 1-dimensional vector space structure as follows from the definition of torus orbifolds. Then there is a unique isomorphism $\varphi_{i}: S^{1} \rightarrow \tilde{S}_{i}$ such that $\varphi_{i}(z)$ acts by the complex multiplication of $z \in S^{1} \subset$ $\mathbb{C}$ on $V_{i} . \varphi_{i}$ depends only on $X_{i}$, not on particular choice of $x$. Let $\pi: \tilde{S}_{i} \rightarrow S_{i}$ denote the covering projection. The homomorphism $\rho_{i}=\pi \circ \varphi_{i}: S^{1} \rightarrow S_{i} \subset T$ defines an element $v_{i} \in \operatorname{Hom}\left(S^{1}, T\right)=H_{2}(B T, \mathbb{Z})$. Then $C(X)(I)$ is the cone in $N=H_{2}(B T, \mathbb{Z})$ with apex at 0 and spanned by $\left\{v_{i} \mid i \in I\right\}$.

Let $\Delta=(\Sigma, C, w)$ be a simplicial multi-fan in a lattice $N$. The Stanley-Reisner ring or the face ring of the simplicial set $\Sigma$ is denoted by $H_{T}^{*}(\Delta)$. It is the quotient ring of the polynomial ring $\mathbb{Z}\left[x_{i} \mid i \in \Sigma^{(1)}\right]$ by the ideal generated by

$$
\left\{x_{K}=\prod_{i \in K} x_{i} \mid K \subset \Sigma^{(1)}, K \notin \Sigma\right\} .
$$

When $\Delta$ is the fan $\Delta_{X}$ associated to a torus orbifold $X, H_{T}^{*}\left(\Delta_{X}\right)_{\mathbb{Q}}$ can be identified with a subring of the equivariant cohomology ring $H_{T}^{*}(X)_{\mathbb{Q}}$ of $X$ with respect to the action of compact torus $T$ acting on $X$ (see [10]). (Hereafter we shall use notation $H_{T}^{*}()_{\mathbb{Q}}$ to mean $H_{T}^{*}() \otimes \mathbb{Q}$.)

In the sequel we shall often consider a set $\mathcal{V}$ consisting of non-zero edge vectors $v_{i}$ for each $i \in \Sigma^{(1)}$ such that $v_{i} \in N \cap C(i)$. We do not require $v_{i}$ to be primitive. This has meaning for torus orbifolds. For any $K \in \Sigma$ put $\mathcal{V}_{K}=\left\{v_{i}\right\}_{i \in K}$. Let $N_{K, \mathcal{V}}$ be the sublattice of $N_{K}$ generated by $\mathcal{V}_{K}$. The quotient group $N_{K} / N_{K, \mathcal{V}}$ is denoted by $H_{K, \mathcal{V}}$.

Let $\mathcal{V}=\left\{v_{i}\right\}_{i \in \Sigma^{(1)}}$ be a set of prescribed edge vectors as before. We define a homomorphism $M=N^{*}=H_{T}^{2}(p t) \rightarrow H_{T}^{2}(\Delta)$ by the formula

$$
\begin{equation*}
u=\sum_{i \in \Sigma^{(1)}}\left\langle u, v_{i}\right\rangle x_{i} . \tag{6}
\end{equation*}
$$

This extends to a homomorphism $H_{T}^{*}(p t) \rightarrow H_{T}^{*}(\Delta)$ and makes $H_{T}^{*}(\Delta)$ a ring over $H_{T}^{*}(p t)\left(\right.$ regarded as embedded in $\left.H_{T}^{*}(\Delta)\right)$.

Since this definition depends on the set $\mathcal{V}$, the $H_{T}^{*}(p t)$-module structure of $H_{T}^{*}(\Delta)$ also depends on $\mathcal{V}$. To emphasize this fact we shall use the notation $H_{T}^{*}(\Delta, \mathcal{V})$. When all the $v_{i}$ are taken primitive, the notation $H_{T}^{*}(\Delta)$ is used.

Fix $I \in \Sigma^{(n)}$ and let $\left\{u_{i}^{I}\right\}_{i \in I}$ be the basis of $N^{*}=H^{2}(p t)$ dual to $\left\{v_{i}\right\}_{i \in I}$. Define $\iota_{I}^{*}: H_{T}^{2}(\Delta)_{\mathbb{Q}} \rightarrow M_{\mathbb{Q}}=H_{T}^{2}(p t)_{\mathbb{Q}}$ by

$$
\begin{equation*}
\iota_{I}^{*}\left(\sum_{i \in \Sigma^{(1)}} d_{i} x_{i}\right)=\sum_{i \in I} d_{i} u_{i}^{I} . \tag{7}
\end{equation*}
$$

$\iota_{I}^{*}$ extends to $H_{T}^{*}(\Delta)_{\mathbb{Q}} \rightarrow H_{T}^{*}(p t)_{\mathbb{Q}}$. It is an $H_{T}^{*}(p t)_{\mathbb{Q}}$-module map, since

$$
\iota_{I}^{*}(u)=u \quad \text { for } \quad u \in H_{T}^{*}(p t)_{\mathbb{Q}} .
$$

Let $S$ be the multiplicative set in $H_{T}^{*}(p t)_{\mathbb{Q}}$ generated by non-zero elements in $H_{T}^{2}(p t)_{\mathbb{Q}}$. The push-forward $\pi_{*}: H_{T}^{*}(\Delta)_{\mathbb{Q}} \rightarrow S^{-1} H_{T}^{*}(p t)_{\mathbb{Q}}$ is defined by

$$
\begin{equation*}
\pi_{*}(x)=\sum_{I \in \Sigma^{(n)}} \frac{l_{I}^{*}(x)}{\left|H_{I}\right| \prod_{i \in I} u_{i}^{I}} . \tag{8}
\end{equation*}
$$

It is an $H_{T}^{*}(p t)_{\mathbb{Q}}$-module map, and lowers the degrees by $2 n$. It is known [7] that, if $\Delta$ is a complete simplicial multi-fan, then the image of $\pi_{*}$ lies in $H_{T}^{*}(p t)_{\mathbb{Q}}$.

Assume that $\Delta$ is complete. Let $p_{*}: H_{T}^{*}(\Delta)_{\mathbb{Q}} \rightarrow \mathbb{Q}$ be the composition of $\pi_{*}: H_{T}^{*}(\Delta)_{\mathbb{Q}} \rightarrow H_{T}^{*}(p t)_{\mathbb{Q}}$ and $H_{T}^{*}(p t)_{\mathbb{Q}} \rightarrow H_{T}^{0}(p t)_{\mathbb{Q}}=\mathbb{Q}$. Note that $p_{*}$ induces $\int_{\Delta}: H^{*}(\Delta)_{\mathbb{Q}} \rightarrow \mathbb{Q}$ as noted in [7] where $H^{*}(\Delta)_{\mathbb{Q}}$ is the quotient of $H_{T}^{*}(\Delta)_{\mathbb{Q}}$ by the ideal generated by $H_{T}^{+}(p t)_{\mathbb{Q}}$. Note that $H^{*}(\Delta)_{\mathbb{Q}}$ is defined independently of $\mathcal{V}$. If $\bar{x}$ denotes the image of $x \in H_{T}^{*}(\Delta)_{\mathbb{Q}}$ in $H^{*}(\Delta)_{\mathbb{Q}}$, then $\int_{\Delta} \bar{x}=p_{*}(x)$.

If $X$ a torus orbifold such that $\Delta_{X}=\Delta$ then $H_{T}^{*}(\Delta)_{\mathbb{Q}}$ is a subring of $H_{T}^{*}(X)_{\mathbb{Q}}$. From this it follows that $p_{*}$ on $H_{T}^{*}(\Delta)_{\mathbb{Q}}$ is the restriction of $p_{*}: H_{T}^{*}(X)_{\mathbb{Q}} \rightarrow \mathbb{Q}$ and $\int_{\Delta}$ is the ordinary integral $\int_{X}$ (see [7]).

Let $K \in \Sigma^{(k)}$ and let $\Delta_{K}=\left(\Sigma_{K}, C_{K}, w_{K}\right)$ be the projected multi-fan. The link Lk $K$ of $K$ in $\Sigma$ is a simplicial complex consisting of simplices $J$ such that $K \cup J \in \Sigma$ and $K \cap J=\emptyset$. It will be denoted by $\Sigma_{K}^{\prime}$ in the sequel. There is an isomorphism from $\Sigma_{K}^{\prime}$ to $\Sigma_{K}$ sending $J \in \Sigma^{\prime}{ }_{K}$ to $J \cup K$. Let $\mathcal{V}=\left\{v_{i}\right\}_{i \in \Sigma^{(1)}}$ be a set of prescribed edge vectors as before. Let $\left\{u_{i}^{K}\right\}_{i \in K}$ be the basis of $N_{K, \mathcal{V}}^{*}$ dual to $\mathcal{V}_{K}$. We consider the polynomial ring $R_{K}$ generated by $\left\{x_{i} \mid i \in K \cup \Sigma_{K}^{\prime(1)}\right\}$ and the ideal $\mathcal{I}_{K}$ generated by monomials $x_{J}=\prod_{i \in J} x_{i}$ such that $J \notin \Sigma(K) * \Sigma_{K}^{\prime}$ where $\Sigma(K) * \Sigma_{K}^{\prime}$ is the join of $\Sigma(K)$ and $\Sigma_{K}^{\prime}$. We define the equivariant cohomology $H_{T}^{*}\left(\Delta_{K}\right)$ of $\Delta_{K}$ with respect to the torus $T$ as the quotient ring $R_{K} / \mathcal{I}_{K}$.

If $\mathcal{V}$ is a set of prescribed edge vectors, $H_{T}^{2}(p t)$ is regarded as a submodule of $H_{T}^{2}\left(\Delta_{K}\right)$ by a formula similar to (6). This defines an $H_{T}^{*}(p t)$-module structure on $H_{T}^{*}\left(\Delta_{K}\right)$ which will be denoted by $H_{T}^{*}\left(\Delta_{K}, \mathcal{V}\right)$ to specify the dependence on $\mathcal{V}$. The projection $H_{T}^{*}(\Delta, \mathcal{V}) \rightarrow H_{T}^{*}\left(\Delta_{K}, \mathcal{V}\right)$ is defined by sending $x_{i}$ to $x_{i}$ for $i \in K \cup \Sigma_{K}^{\prime(1)}$ and putting $x_{i}=0$ for $i \notin K \cup \Sigma_{K}^{\prime(1)}$. The restriction homomorphism $\iota_{I}^{*}: H_{T}^{*}\left(\Delta_{K}, \mathcal{V}\right)_{\mathbb{Q}} \rightarrow$ $H_{T}^{*}(p t)_{\mathbb{Q}}$ for $I \in \Sigma_{K}^{(n-k)}$ and the push-forward $\pi_{*}: H_{T}^{*}\left(\Delta_{K}, \mathcal{V}\right)_{\mathbb{Q}} \rightarrow S^{-1} H_{T}^{*}(p t)_{\mathbb{Q}}$ are also defined in a similar way as before.

Given $\xi=\sum_{i \in K \cup \Sigma_{K}^{(1)}} d_{i} x_{i} \in H_{T}^{2}\left(\Delta_{K}, \mathcal{V}\right)_{\mathbb{R}}, d_{i} \in \mathbb{R}$, let $A_{K}^{*}$ be the affine subspace in the space $M_{\mathbb{R}}$ defined by $\left\langle u, v_{i}\right\rangle=d_{i}$ for $i \in K$. Then we introduce a collection $\mathcal{F}_{K}=\left\{F_{i} \mid i \in \Sigma_{K}^{\prime(1)}\right\}$ of affine hyperplanes in $A_{K}^{*}$ by setting

$$
F_{i}=\left\{u \mid u \in A_{K}^{*},\left\langle u, v_{i}\right\rangle=d_{i}\right\}
$$

The pair $\mathcal{P}_{K}(\xi)=\left(\Delta_{K}, \mathcal{F}_{K}\right)$ will be called a multi-polytope associated with $\xi$; see [8]. In case $K=o \in \Sigma^{(0)}, \mathcal{P}_{K}(\xi)$ is simply denoted by $\mathcal{P}(\xi)$.

For $\xi=\sum_{i \in \Sigma^{(1)}} d_{i} x_{i}$ and $K \in \Sigma^{(k)}$ put $\xi_{K}=\sum_{i \in K \cup \Sigma_{K}^{(1)}} d_{i} x_{i}$ and $\mathcal{P}(\xi)_{K}=\mathcal{P}_{K}\left(\xi_{K}\right)$. It will be called the face of $\mathcal{P}(\xi)$ corresponding to $K$.

For $I \in \Sigma_{K}^{(n-k)}$, i.e. $I \in \Sigma^{(n)}$ with $I \supset K$, we put $u_{I}=\bigcap_{i \in I} F_{i}=\bigcap_{i \in I \backslash K} F_{i} \cap A_{K}^{*} \in$ $A_{K}^{*}$. Note that $u_{I}$ is equal to $\iota_{I}^{*}(\xi)$. The dual vector space $\left(N_{\mathbb{R}}^{K}\right)^{*}$ of $N_{\mathbb{R}}^{K}$ is canonically identified with the subspace $M_{K \mathbb{R}}$ of $M_{\mathbb{R}}=H_{T}^{2}(p t)_{\mathbb{R}}$. It is parallel to $A_{K}^{*}$, and $u_{i}^{I}$ lies in $M_{K \mathbb{R}}$ for $I \in \Sigma_{K}^{(n-k)}$ and $i \in I \backslash K$. A vector $v \in N_{\mathbb{R}}^{K}$ is called generic if $\left\langle u_{i}^{I}, v\right\rangle \neq 0$ for any $I \in \Sigma_{K}^{(n-k)}$ and $i \in I \backslash K$. The image in $N_{\mathbb{R}}^{K}$ of a generic vector in $N_{\mathbb{R}}$ is generic. Take a generic vector $v \in N_{\mathbb{R}}^{K}$, and define

$$
(-1)^{I}:=(-1)^{\left.\#|j \in I \backslash K|\left\langle u_{j}^{I}, v\right\rangle>0\right\}}
$$

and

$$
\left(u_{i}^{I}\right)^{+}:=\left\{\begin{array}{lll}
u_{i}^{I} & \text { if } & \left\langle u_{i}^{I}, v\right\rangle>0 \\
-u_{i}^{I} & \text { if } & \left\langle u_{i}^{I}, v\right\rangle<0,
\end{array}\right.
$$

for $I \in \Sigma_{K}^{(n-k)}$ and $i \in I \backslash K$. We denote by $C_{K}^{*}(I)^{+}$the cone in $A_{K}^{*}$ spanned by the $\left(u_{i}^{I}\right)^{+}, i \in I \backslash K$, with apex at $u_{I}$, and by $\phi_{I}$ its characteristic function. With these understood, we define a function $\mathrm{DH}_{\mathcal{P}_{K}(\xi)}$ on $A_{K}^{*} \backslash \bigcup_{i} F_{i}$ by

$$
\mathrm{DH}_{\mathcal{P}_{K}(\xi)}=\sum_{I \in \Sigma_{K}^{(n-k)}}(-1)^{I} w(I) \phi_{I} .
$$

As in [8] we call this function the Duistermaat-Heckman function associated with $\mathcal{P}_{K}(\xi)$. When $K=o, \mathrm{DH}_{\mathcal{P}(\xi)}$ is defined on $M_{\mathbb{R}} \backslash \bigcup_{i} F_{i}$.

The following theorem is fundamental in the sequel, cf. [8] Theorem 2.3 and [7] Corollary 7.4.

Theorem 2.1. Let $\Delta$ be a complete simplicial multi-fan. Let $\xi=\sum_{i \in K \cup \Sigma_{K}^{\prime}{ }^{(1)}} d_{i} x_{i} \in$ $H_{T}^{2}\left(\Delta_{K}, \mathcal{V}\right)$ be as above with all $d_{i}$ integers and put $\xi_{+}=\sum_{i}\left(d_{i}+\epsilon\right) x_{i}$ with $0<\epsilon<1$. Then

$$
\begin{equation*}
\sum_{u \in A_{K}^{*} \cap M} \mathrm{DH}_{\mathcal{P}_{K}\left(\xi_{+}\right)}(u) t^{u}=\sum_{I \in \Sigma_{K}^{(n-k)}} \frac{w(I)}{\left|H_{I, \mathcal{V}}\right|} \sum_{h \in H_{I, \mathcal{V}}} \frac{\chi_{I}\left(l_{I}^{*}(\xi), h\right) t_{t_{I}^{*}(\xi)}}{\prod_{i \in I \backslash K}\left(1-\chi_{I}\left(u_{i}^{I}, h\right)^{-1} t^{-u_{i}^{l}}\right)}, \tag{9}
\end{equation*}
$$

where $\chi_{I}(u, h)=e^{2 \pi \sqrt{-1}(u, v(h)\rangle}$ for $u \in N_{I, \mathcal{V}}^{*}$ and $v(h)$ is a lift of $h \in H_{I, \mathcal{V}}$ to $N_{I, \mathcal{V}}$.
Note. The left hand side of (9) is considered as an element in the group ring of $M$ over $\mathbb{R}$ or the character ring $R(T) \otimes \mathbb{R}$ considered as the Laurent polynomial ring in $t=\left(t_{1}, \ldots, t_{n}\right)$. The equality shows that the right hand side, which is a rational function of $t$, belongs to $R(T) \otimes \mathbb{R}$.
$\xi=\sum_{i} d_{i} x_{i} \in H_{T}^{2}(\Delta, \mathcal{V})$ is called $T$-Cartier if $\iota_{I}^{*}(\xi) \in M$ for all $I \in \Sigma^{(n)}$. This condition is equivalent to $u_{I} \in M$ for all $I \in \Sigma^{(n)}$. In this case $\mathcal{P}(\xi)$ is said lattice
multi-polytope. If $\xi$ is $T$-Cartier, then $\chi_{I}\left(\iota_{I}^{*}(\xi), h\right) \equiv 1$. Hence the above formula (9) for $\mathrm{DH}_{\mathcal{P}_{K}\left(\xi_{K_{+}}\right)}$reduces in this case to

$$
\begin{equation*}
\sum_{u \in A_{K}^{*} \cap M} \mathrm{DH}_{\mathcal{P}_{K}\left(\xi_{K+}\right)}(u) t^{u}=\sum_{I \in \Sigma_{K}^{(n-k)}} \frac{w(I)}{\left|H_{I, \mathcal{V}}\right|} \sum_{h \in H_{l, \mathcal{V}}} \frac{t^{t_{i}^{*}\left(\xi_{K}\right)}}{\prod_{i \in I \backslash K}\left(1-\chi_{I}\left(u_{i}^{I}, h\right)^{-1} t^{-u_{i}^{l}}\right)} . \tag{10}
\end{equation*}
$$

Let $H_{T}^{* *}()$ denote the completed equivariant cohomology ring. The Chern character ch sends $R(T) \otimes \mathbb{R}$ to $H_{T}^{* *}(p t)_{\mathbb{R}}$ by $\operatorname{ch}\left(t^{u}\right)=e^{u}$. The image of (10) by ch is given by

$$
\begin{equation*}
\sum_{u \in A_{K}^{*} \cap M} \operatorname{DH}_{\mathcal{P}_{K}\left(\xi_{K}\right)}(u) e^{u}=\sum_{I \in \Sigma_{K}^{(n-k)}} \frac{w(I)}{\left|H_{I, \mathcal{V}}\right|} \sum_{h \in H_{l, \mathcal{V}}} \frac{e^{l_{i}^{*}\left(\xi_{K}\right)}}{\prod_{i \in I \backslash K}\left(1-\chi_{I}\left(u_{i}^{I}, h\right)^{-1} e^{-u_{i}^{I}}\right)} . \tag{11}
\end{equation*}
$$

Assume that $\xi=\sum_{i} d_{i} x_{i} \in H_{T}^{2}(\Delta, \mathcal{V})$ is $T$-Cartier. The number $\#\left(\mathcal{P}(\xi)_{K}\right)$ is defined by

$$
\#\left(\mathcal{P}(\xi)_{K}\right)=\sum_{u \in A_{K}^{*} \cap M} \mathrm{DH}_{\mathcal{P}_{K}\left(\xi_{K+}\right)}(u) .
$$

It is obtained from (11) by setting $u=0$, that is, it is equal to the image of (11) by $H_{T}^{* *}(p t)_{\mathbb{Q}} \rightarrow H_{T}^{0}(p t)_{\mathbb{Q}}$.

The equivariant Todd class $\mathcal{T}_{T}(\Delta, \mathcal{V})$ is defined in such a way that

$$
\pi_{*}\left(e^{\xi} \mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\sum_{u \in M} \mathrm{DH}_{\mathcal{P}\left(\xi_{+}\right)}(u) e^{u}
$$

for $\xi T$-Cartier. In order to give the definition we need some notations.
For simplicity identify the set $\Sigma^{(1)}$ with $\{1,2, \ldots, m\}$ and consider a homomorphism $\eta: \mathbb{R}^{m}=\mathbb{R}^{\Sigma^{(1)}} \rightarrow N_{\mathbb{R}}$ sending $\mathbf{a}=\left(a_{1}, a_{2}, \ldots, a_{m}\right)$ to $\sum_{i \in \Sigma^{(1)}} a_{i} v_{i}$. For $K \in \Sigma^{(k)}$ we define

$$
\tilde{G}_{K, \mathcal{V}}=\left\{\mathbf{a} \mid \eta(\mathbf{a}) \in N \text { and } a_{j}=0 \text { for } j \notin K\right\}
$$

and define $G_{K, \mathcal{V}}$ to be the image of $\tilde{G}_{K, \mathcal{V}}$ in $\tilde{T}=\mathbb{R}^{m} / \mathbb{Z}^{m}$. It will be written $G_{K}$ for simplicity. The homomorphism $\eta$ restricted on $\tilde{G}_{K, \mathcal{V}}$ induces an isomorphism

$$
\eta_{K}: G_{K} \cong H_{K, \mathcal{V}} \subset T=N_{\mathbb{R}} / N
$$

Put

$$
G_{\Delta}=\bigcup_{I \in \Sigma^{(n)}} G_{I} \subset \tilde{T}
$$

and

$$
D G_{\Delta}=\bigcup_{I \in \Sigma^{(n)}} G_{I} \times G_{I} \subset G_{\Delta} \times G_{\Delta}
$$

Let $v(g)=\mathbf{a}=\left(a_{1}, a_{2}, \ldots, a_{m}\right) \in \mathbb{R}^{m}$ be a representative of $g \in \tilde{T}$. The factor $a_{i}$ will be denoted by $v_{i}(g)$. It is determined modulo integers. If $g \in G_{I}$, then $v_{i}(g)$ is necessarily a rational number. Define a homomorphism $\chi_{i}: \tilde{T} \rightarrow \mathbb{C}^{*}$ by

$$
\chi_{i}(g)=e^{2 \pi \sqrt{-1} v_{i}(g)} .
$$

Let $g \in G_{I}$ and $h=\eta_{I}(g) \in H_{I, \mathcal{V}}$. Then $\eta(v(g)) \in N_{I}$ is a representative of $h$ in $N_{I}$ which will be denoted by $v(h)$. Then, for $g \in G_{I}$ and $i \in I$,

$$
v_{i}(g) \equiv\left\langle u_{i}^{I}, v(h)\right\rangle \quad \bmod \mathbb{Z},
$$

and

$$
\chi_{i}(g)=e^{2 \pi \sqrt{-1}\left\langle u_{i}^{I}, v(h)\right\rangle}=\chi_{I}\left(u_{i}^{I}, h\right) .
$$

Let $\Delta$ be a complete simplicial multi-fan. Define

$$
\mathcal{T}_{T}(\Delta, \mathcal{V})=\sum_{g \in G_{\Delta}} \prod_{i \in \Sigma^{(1)}} \frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}} \in H_{T}^{* *}(\Delta, \mathcal{V})_{\mathbb{Q}}
$$

Proposition 2.2. Let $\Delta$ be a complete simplicial multi-fan. Assume that $\xi \in$ $H_{T}^{2}(\Delta, \mathcal{V})$ is $T$-Cartier. Then

$$
\pi_{*}\left(e^{\xi} \mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\sum_{u \in M} \mathrm{DH}_{\mathcal{P}\left(\xi_{+}\right)}(u) e^{u}
$$

## Consequently

$$
p_{*}\left(e^{\xi} \mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\#(\mathcal{P}(\xi))
$$

Proof (cf. [7] Section 8). Let $g \in G_{\Delta}$ and $I \in \Sigma^{(n)}$. If $g \notin G_{I}$, then there is an element $i \notin I$ such that $\chi_{i}(g) \neq 1$; so

$$
\frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}=\left(1-\chi_{i}(g)\right)^{-1} x_{i}+\text { higher degree terms }
$$

for such $i$. Hence $i_{I}^{*}\left(x_{i} /\left(1-\chi_{i}(g) e^{-x_{i}}\right)\right)=0$. Therefore, only elements $g$ in $G_{I}$ contribute to $\iota_{I}^{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)$. Now suppose $g \in G_{I}$. Then $\chi_{i}(g)=1$ for $i \notin I$, so $\iota_{I}^{*}\left(x_{i} /(1-\right.$ $\left.\left.\chi_{i}(g) e^{-x_{i}}\right)\right)=1$ for such $i$. Finally, since $\iota_{I}^{*}\left(x_{i}\right)=u_{i}^{I}$ for $i \in I$, we have

$$
\iota_{I}^{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\sum_{g \in G_{I}} \prod_{i \in I} \frac{u_{i}^{I}}{1-\chi_{i}(g) e^{-u_{i}^{i}}}
$$

This together with (11) shows that

$$
\begin{aligned}
\pi_{*}\left(e^{\xi} \mathcal{T}_{T}(\Delta, \mathcal{V})\right) & =\pi_{*}\left(e^{\xi} \sum_{g \in G_{\Delta}} \prod_{i=1}^{m} \frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}\right) \\
& =\sum_{I \in \Sigma^{(n)}} \frac{w(I) e^{t_{i}^{*}(\xi)}}{\left|H_{I, \mathcal{V}}\right|} \sum_{g \in G_{I}} \frac{1}{\prod_{i \in I}\left(1-\chi_{i}(g) e^{-u_{i}^{l}}\right)} \\
& =\sum_{u \in M} \operatorname{DH}_{\mathcal{P}\left(\xi_{+}\right)}(u) e^{u}
\end{aligned}
$$

More generally, for $K \in \Sigma^{(k)}$, define $\mathcal{T}_{T}(\Delta, \mathcal{V})_{K}$ by

$$
\mathcal{T}_{T}(\Delta, \mathcal{V})_{K}=\sum_{g \in G_{\Delta_{K}}} \prod_{i \in \Sigma_{K}^{(1)}} \frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}} \in H_{T}^{* *}(\Delta, \mathcal{V})_{\mathbb{Q}}
$$

Then the same proof as for Proposition 2.2 yields
Proposition 2.3. Let $\Delta$ be a complete simplicial multi-fan. Assume that $\xi \in$ $H_{T}^{2}(\Delta, \mathcal{V})$ is $T$-Cartier. Then

$$
\pi_{*}\left(e^{\xi} x_{K} \mathcal{T}_{T}(\Delta, \mathcal{V})_{K}\right)=\sum_{u \in A_{K}^{*} \cap M} \operatorname{DH}_{\mathcal{P}_{K}\left(\xi_{K+}\right)}(u) e^{u}
$$

for $K \in \Sigma^{(k)}$, where $x_{K}=\prod_{i \in K} x_{i}$. Consequently

$$
p_{*}\left(e^{\xi} x_{K} \mathcal{T}_{T}(\Delta, \mathcal{V})_{K}\right)=\#\left(\mathcal{P}(\xi)_{K}\right)
$$

The lattice $M \cap A_{K}^{*}$ defines a volume element $d V_{K}$ on $A_{K}^{*}$. For $\xi=\sum_{i \in K \cup \Sigma_{K}^{\prime}{ }^{(1)}} d_{i} x_{i} \in$ $H_{T}^{2}\left(\Delta_{K}, \mathcal{V}\right)_{\mathbb{R}}$, the volume $\operatorname{vol} \mathcal{P}_{K}(\xi)$ of $\mathcal{P}_{K}(\xi)$ is defined by

$$
\operatorname{vol} \mathcal{P}_{K}(\xi)=\int_{A_{K}^{*}} \operatorname{DH}_{\mathcal{P}_{K}(\xi)} d V_{K}^{*}
$$

Proposition 2.4. For $\xi=\sum_{i \in \Sigma^{(1)}} d_{i} x_{i} \in H_{T}^{2}(\Delta, \mathcal{V})_{\mathbb{R}}$

$$
\frac{1}{\left|H_{K, \mathcal{V}}\right|} \operatorname{vol} \mathcal{P}(\xi)_{K}=p_{*}\left(e^{\xi} x_{K}\right)
$$

Proof. We shall give a proof only for the case where $\xi$ is $T$-Cartier. The general case can be reduced to this case, cf. [7], Lemma 8.6. By Proposition 2.3

$$
\#\left(\mathcal{P}(\xi)_{K}\right)=p_{*}\left(e^{\xi} x_{K} \mathcal{T}_{T}(\Delta, \mathcal{V})_{K}\right)
$$

The highest degree term with respect to $\left\{d_{i}\right\}$ in the right hand side is nothing but $\operatorname{vol} \mathcal{P}(\xi)_{K}$ and is equal to

$$
p_{*}\left(\frac{\xi^{n-k}}{(n-k)!} x_{K}\right) \sum_{g \in G_{\Delta_{K}}}\left(\prod_{i \in \Sigma_{K}^{(1)}} \frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}\right)_{0},
$$

where the suffix 0 means taking 0 -th degree term. But

$$
\left(\prod_{i \in \Sigma_{K}^{\prime(1)}} \frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}\right)_{0}=\left\{\begin{array}{lll}
1 & \text { if } & g \in G_{K}, \\
0 & \text { if } & g \notin G_{K} .
\end{array}\right.
$$

Hence

$$
\operatorname{vol} \mathcal{P}(\xi)_{K}=\left|G_{K}\right| p_{*}\left(\frac{\xi^{n-k}}{(n-k)!} x_{K}\right)=\left|H_{K, \mathcal{V}}\right| p_{*}\left(e^{\xi} x_{K}\right)
$$

## 3. Statement of main results

Assume that $1 \leq k$. For $J \in \Sigma^{(k)}$ let $M_{J}$ be the annihilator of $N_{J}$ and put $\omega_{J}=$ $u_{1} \wedge \ldots \wedge u_{n-k} \in \bigwedge^{n-k} M \subset \bigwedge^{n-k} M_{\mathbb{Q}}$ where $\left\{u_{1}, \ldots, u_{n-k}\right\}$ is an oriented basis of $M_{J}$. Define $f^{J}\left(x_{i}\right) \in \bigwedge^{n-k+1} M_{\mathbb{Q}}$ by

$$
f^{J}\left(x_{i}\right)=\iota_{I}^{*}\left(x_{i}\right) \wedge \omega_{J} \quad \text { with } \quad J \subset I \in \Sigma^{(n)} .
$$

$f^{J}\left(x_{i}\right)$ is well-defined independently of $I$ containing $J$. Let $S^{*}\left(\bigwedge^{n-k+1} M_{\mathbb{Q}}\right)$ be the symmetric algebra over $\bigwedge^{n-k+1} M_{\mathbb{Q}} . \quad f^{J}: H_{T}^{2}(\Delta)_{\mathbb{Q}} \rightarrow \bigwedge^{n-k+1} M_{\mathbb{Q}}$ extends to $f^{J}: H_{T}^{*}(\Delta)_{\mathbb{Q}} \rightarrow S^{*}\left(\bigwedge^{n-k+1} M_{\mathbb{Q}}\right)$. For $x=\prod_{i} x_{i}^{\alpha_{i}} \in H_{T}^{2 k}(\Delta)_{\mathbb{Q}}$ we put

$$
f^{J}(x)=\left(f^{J}\left(x_{i}\right)\right)^{\alpha_{i}} .
$$

The definition of $f^{J}$ depends on the orientations chosen, but $f^{J}(x) / f^{J}\left(x_{J}\right)$ does not. It belongs to the fraction field of the symmetric algebra $S^{*}\left(\bigwedge^{n-k+1} M_{\mathbb{Q}}\right)$ and has degree 0 . Hence it can be considered as an element of $\operatorname{Rat}\left(\mathbb{P}\left(\bigwedge^{n-k+1} N_{\mathbb{Q}}\right)\right)_{0}$, the field of rational functions of degree 0 on $\mathbb{P}\left(\bigwedge^{n-k+1} N_{\mathbb{Q}}\right)$. Let $v^{*}: \operatorname{Rat}\left(\mathbb{P}\left(\bigwedge^{n-k+1} N_{\mathbb{Q}}\right)\right)_{0} \rightarrow$ $\operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)_{0}$ be the induced homomorphism of the Plücker embedding $\nu: G_{n-k+1}\left(N_{\mathbb{Q}}\right) \rightarrow \mathbb{P}\left(\bigwedge^{n-k+1} N_{\mathbb{Q}}\right)$. The image $v^{*}\left(f^{J}(x) / f^{J}\left(x_{J}\right)\right)$ will be denoted by $\mu(x, J)$.

Our first main result is stated in the following
Theorem 3.1. Let $\Delta$ be a complete simplicial multi-fan and $x \in H_{T}^{2 k}(\Delta, \mathcal{V})_{\mathbb{Q}}$. For any $\xi \in H_{T}^{2}(\Delta)_{\mathbb{Q}}$ we have

$$
p_{*}\left(e^{\xi} x\right)=\sum_{J \in \Sigma^{(k)}} \mu(x, J) p_{*}\left(e^{\xi} x_{J}\right) \quad \text { in } \quad \operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)_{0}
$$

Corollary 3.2. Let $\Delta$ be a complete simplicial multi-fan in a lattice of rank $n$. Assume that $\xi \in H_{T}^{2}(\Delta, \mathcal{V})$ is $T$-Cartier. Set

$$
\#(\mathcal{P}(\nu \xi))=\sum_{k=0}^{n} a_{k}(\xi) \nu^{n-k}
$$

Then we have

$$
a_{k}(\xi)=\sum_{J \in \Sigma^{(k)}} \mu_{k}(J) \operatorname{vol} \mathcal{P}(\xi)_{J}
$$

with

$$
\mu_{k}(J)=\frac{1}{\left|H_{J, \mathcal{V}}\right|} v^{*}\left(\sum_{h \in H_{J, V}} \prod_{j \in J} \frac{1}{1-\chi\left(u_{j}^{J}, h\right) e^{-f^{J}\left(x_{j}\right)}}\right)_{0}
$$

in $\operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{C}}\right)\right)_{0}$.
Note. It can be proved without difficulty that $\mu_{k}(J)$ does not depend on the choice of $\mathcal{V}$. Hence one has only to consider the case where all the $v_{i}$ are primitive.

For the following corollary we need to put an additional condition on the multifan $\Delta$.

Corollary 3.3. Let $\Delta$ be a multi-fan. Assume that there is a torus orbifold $X$ such that $\Delta$ is isomorphic to $\Delta_{X}$ and $H^{*}(X)_{\mathbb{Q}}$ is generated by $H^{2}(X)_{\mathbb{Q}}$. Then for $x \in$ $H_{T}^{2 k}(\Delta)_{\mathbb{Q}}$ the following equality holds.

$$
\bar{x}=\sum_{J \in \Sigma^{(k)}} \mu(x, J) \bar{x}_{J} \quad \text { in } \quad \operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)_{0} \otimes_{\mathbb{Q}} H^{2 k}(\Delta)_{\mathbb{Q}}
$$

where $\bar{x}$ is the image of $x \in H_{T}^{*}(\Delta)_{\mathbb{Q}}$ in $H^{*}(\Delta)_{\mathbb{Q}}$.
REmARK 3.1. If $H^{*}(X)_{\mathbb{Q}}$ is generated by $H^{2}(X)_{\mathbb{Q}}$, then $H_{T}^{*}\left(\Delta_{X}\right)_{\mathbb{Q}}=H_{T}^{*}(X)_{\mathbb{Q}}$. cf. [10], [11].

REmARK 3.2. When $\Delta$ is the fan associated to a convex lattice polytope $P$ and $\xi=D$, the Cartier divisor associated to $P$, we know (see, e.g. [5]) that

$$
\mu_{0}(o)=1, \quad a_{0}(\xi)=\operatorname{vol} \mathcal{P}(\xi), \quad \mu_{1}(i)=\frac{1}{2}, \quad a_{1}(\xi)=\frac{1}{2} \sum_{i \in \Sigma^{(1)}} \operatorname{vol} \mathcal{P}(\xi)_{i} .
$$

This is also true for simplicial multi-fans and $T$-Cartier $\xi$.

As to $a_{n}$ we have

$$
a_{n}(\xi)=\operatorname{Td}[\Delta] .
$$

In fact $a_{n}(\xi)=p_{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\left(\pi_{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)\right)_{0}$. Thus the above equality follows from the following rigidity property:

Theorem 3.4. Let $\Delta$ be a complete simplicial multi-fan. Then

$$
\pi_{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\left(\pi_{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)\right)_{0}=\operatorname{Td}[\Delta] .
$$

See [7] Theorem 7.2 and its proof. Note that $\operatorname{Td}[\Delta]=1$ for any complete simplicial fan $\Delta$.

The explicit formula for $\pi_{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)$ is given by

$$
\pi_{*}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\sum_{I \in \Sigma^{(n)}} \frac{w(I)}{\left|H_{I, \mathcal{V}}\right|} \sum_{h \in H_{I, \mathcal{V}}} \prod_{i \in I} \frac{1}{1-\chi_{I}\left(u_{i}^{I}, h\right) e^{-u_{i}^{l}}}
$$

This does not depend on the choice of $\mathcal{V}$ and is in fact equal to $\operatorname{Td}[\Delta]$.
Let $\Delta$ be a (not necessarily complete) simplicial fan in a lattice of rank $n$. Set

$$
\operatorname{Td}_{T}(\Delta)=\sum_{I \in \Sigma^{(n)}} \frac{1}{\left|H_{I}\right|} \sum_{h \in H_{I}} \prod_{i \in I} \frac{1}{1-\chi_{I}\left(u_{i}^{I}, h\right) e^{-u_{i}^{l}}} \in S^{-1} H_{T}^{* *}(p t)_{\mathbb{Q}} .
$$

For a simplex $I$ let $\Sigma(I)$ be the simplicial complex consisting of all faces of $I$. For a fan $\Delta(I)=(\Sigma(I), C), \operatorname{Td}_{T}(\Delta(I))$ is denoted by $\operatorname{Td}_{T}(I)$.

Theorem 3.5. $\operatorname{Td}_{T}(I)$ is additive with respect to simplicial subdivisions of the cone $C(I)$. Namely, if $\Delta$ is the fan determined by a simplicial subdivison of $C(I)$, then the following equality holds

$$
\operatorname{Td}_{T}(\Delta)=\operatorname{Td}_{T}(I)
$$

For the proof it is sufficient to assume that $\Delta(I)$ and $\Delta$ are non-singular. In such a form a proof is given in [12]. The following corollary ensures that $\mu_{k}(J)$ can be defined for general polyhedral cones as pointed out by Morelli in [12].

Corollary 3.6. Let $\Delta(J)=(\Sigma(J), C)$ be a fan in a lattice $N$ of rank $n$ where $J$ is a simplex of dimension $k-1$. Then $\mu_{k}(J) \in \operatorname{Rat}\left(G_{n-k+1}\left(N_{\mathbb{Q}}\right)\right)_{0}$ is additive with respect to simplicial subdivisions of $C(J)$.

## 4. Proof of Theorem 3.1 and Corollary 3.3

Proof of Theorem 3.1.
For a primitive sublattice $E$ of $N$ of rank $n-k+1$ let $w_{E} \in \bigwedge^{n-k+1} N$ be a representative of $\nu(E) \in \mathbb{P}\left(\bigwedge^{n-k+1} N_{\mathbb{Q}}\right)$. The equality in Theorem 3.1 is equivalent to the condition that

$$
p_{*}\left(e^{\xi} x\right)=\sum_{J \in \Sigma^{(k)}} \frac{f^{J}(x)}{f^{J}\left(x_{J}\right)}\left(w_{E}\right) p_{*}\left(e^{\xi} x_{J}\right) \quad \text { holds for every generic } \quad E .
$$

Let $E$ be a generic primitive sublattice in $N$ of rank $n-k+1$. The intersection $E \cap N_{J}$ has rank one for each $J \in \Sigma^{(k)}$. Take a non-zero vector $v_{E, J}$ in $E \cap N_{J}$. (One can choose $v_{E, J}$ to be the unique primitive vector contained in $E \cap C(J)$. But any non-zero vector will suffice for the later use.) For $x \in H_{T}^{2 k}(\Delta)$ and $J \in \Sigma^{(k)}$ the value of $\iota_{I}^{*}(x)$ evaluated on $v_{E, J}$ for $I \in \Sigma^{(n)}$ containing $J$ depends only on $\iota_{J}^{*}(x)$ so that it will be denoted by $l_{J}^{*}(x)\left(v_{E, J}\right)$. Similarly we shall simply write $\left\langle u_{j}^{J}, v_{E, J}\right\rangle$ instead of $\left\langle u_{j}^{I}, v_{E, J}\right\rangle$.

Lemma 4.1. Put $f_{j}^{J}=u_{j}^{J} \wedge \omega_{J}$. Then

$$
a\left\langle f_{j}^{J}, w_{E}\right\rangle=\left\langle u_{j}^{J}, v_{E, J}\right\rangle,
$$

where $a$ is a non-zero constant depending only on $v_{E, J}$.
Proof. Take an oriented basis $u_{1}, \ldots, u_{n-k}$ of $M_{J}$. Take also a basis $w_{1}, \ldots, w_{n-k+1}$ of $E$ and write $v_{E, J}=\sum_{l} c_{l} w_{l}$. Then, since $\left\langle u_{i}, v_{E, J}\right\rangle=0$,

$$
\sum_{l=1}^{n-k+1} c_{l}\left\langle u_{i}, w_{l}\right\rangle=0, \quad \text { for } \quad i=1, \ldots, n-k
$$

The matrix $\left(a_{i l}\right)=\left(\left\langle u_{i}, w_{l}\right\rangle\right)$ has rank $n-k$ and we get

$$
\left(c_{1}, \ldots, c_{n-k+1}\right)=a\left(A_{1}, \ldots, A_{n-k+1}\right), \quad a \neq 0
$$

where

$$
A_{l}=(-1)^{l-1} \operatorname{det}\left(\begin{array}{ccccc}
a_{11} & \cdots & \widehat{a_{1 l}} & \cdots & a_{1 n-k+1} \\
\vdots & & \vdots & & \vdots \\
a_{n-k 1} & \cdots & \widehat{a_{n-k l}} & \cdots & a_{n-k n-k+1}
\end{array}\right) .
$$

Then

$$
\begin{aligned}
\left\langle u_{j}^{J}, v_{E, J}\right\rangle & =\sum_{l=1}^{n-k+1} c_{l}\left\langle u_{j}^{J}, w_{l}\right\rangle \\
& =a \sum_{l=1}^{n-k+1}\left\langle u_{j}^{J}, w_{l}\right\rangle A_{l} \\
& =a \operatorname{det}\left(\begin{array}{ccc}
\left\langle u_{j}^{J}, w_{1}\right\rangle & \cdots & \left\langle u_{j}^{J}, w_{n-k+1}\right\rangle \\
\left\langle u_{1}, w_{1}\right\rangle & \cdots & \left\langle u_{1}, w_{n-k+1}\right\rangle \\
\vdots & & \vdots \\
\left\langle u_{n-k}, w_{1}\right\rangle & \cdots & \left\langle u_{n-k}, w_{n-k+1}\right\rangle
\end{array}\right) \\
& =a\left\langle f_{j}^{J}, w_{E}\right\rangle
\end{aligned}
$$

where $f_{j}^{J}=u_{j}^{J} \wedge u_{1} \wedge \cdots \wedge u_{n-k}$ and $w_{E}=w_{1} \wedge \cdots \wedge w_{n-k+1}$.

REMARK 4.1. Let $X$ be a torus orbifold of dimension $2 n$ and $\Delta$ the associated multifan. Let $T=T^{n}$ be the compact torus acting on $X . E \cap N_{J}$ determines a subcircle $T_{E, J}^{1}$ of $T$. Then $T_{E, J}^{1}$ pointwise fixes an invariant complex suborbifold $X_{J}$. Some of its covering acts on the normal vector space of an Euclidean covering of an invariant neighborhood at each generic point in $X_{J}$. Then the numbers $\left\langle u_{j}^{J}, v_{E, J}\right\rangle$ are weights of this action.

Lemma 4.1 implies that

$$
\frac{f^{J}(x)}{f^{J}\left(x_{J}\right)}\left(w_{E}\right)=\frac{\iota_{J}^{*}(x)}{\prod_{j \in J} u_{j}^{J}}\left(v_{E, J}\right)
$$

Then the equality in Theorem 3.1 holds if and only if

$$
\begin{equation*}
p_{*}\left(e^{\xi} x\right)=\sum_{J \in \Sigma^{(k)}} a \frac{\iota_{J}^{*}(x)}{\prod_{j \in J} u_{j}^{J}}\left(v_{E, J}\right) p_{*}\left(e^{\xi} x_{J}\right) \tag{12}
\end{equation*}
$$

holds for every generic $E$.
The following lemma is easy to prove, cf. e.g. [7] Lemma 8.1.
Lemma 4.2. The vector space $H_{T}^{2 k}(\Delta)_{\mathbb{Q}}$ is spanned by elements of the form

$$
u_{1} \cdots u_{k_{1}} x_{J_{k_{1}}}, \quad J_{k_{1}} \in \Sigma^{\left(k-k_{1}\right)}, \quad u_{i} \in M_{\mathbb{Q}}
$$

with $0 \leq k_{1} \leq k-1$.

Note. For $x=u_{1} \cdots u_{k_{1}} x_{J_{k_{1}}}, J_{k_{1}} \in \Sigma^{\left(k-k_{1}\right)}$, with $k_{1} \geq 1$,

$$
p_{*}\left(e^{\xi} x\right)=0
$$

In view of this lemma we proceed by induction on $k_{1}$ for $x=u_{1} \cdots u_{k_{1}} x_{J_{k_{1}}}$.
For $x=x_{J_{0}}$ with $J_{0} \in \Sigma^{(k)}$, the left hand side of (12) is equal to $p_{*}\left(e^{\xi} x_{J_{0}}\right)$. Since $i_{J}^{*}(x)=0$ unless $J=J_{0}$ and $i_{J}^{*}(x) / \prod_{j \in J} u_{j}^{J}=1$ for $J=J_{0}$, the right hand side is also equal to $p_{*}\left(e^{\xi} x_{J_{0}}\right)$. Hence (12) holds with $x$ of the form $x=x_{J_{0}}$ for $J_{0} \in \Sigma^{(k)}$.

Assuming that (12) holds for $x$ of the form $u_{1} \cdots u_{k_{1}} x_{J_{k_{1}}}$ with $J_{k_{1}} \in \Sigma^{\left(k-k_{1}\right)}$, we shall prove that it also holds for $x=u_{1} \cdots u_{k_{1}} u_{k_{1}+1} x_{J_{k_{1}+1}}$ with $J_{k_{1}+1} \in \Sigma^{\left(k-\left(k_{1}+1\right)\right)}$. Put $K=J_{k_{1}+1}$.

CASE a). $u_{k_{1}+1}$ belongs to $M_{K \mathbb{Q}}$, that is, $\left\langle u_{k_{1}+1}, v_{i}\right\rangle=0$ for all $i \in K$. In this case

$$
u_{k_{1}+1}=\sum_{i \in \Sigma^{(1)} \backslash K}\left\langle u_{k_{1}+1}, v_{i}\right\rangle x_{i}
$$

since $\left\langle u_{k_{1}+1}, v_{i}\right\rangle=0$ for all $i \in K$. For $i \notin K, x_{i} x_{J_{k_{1}+1}}$ is either of the form $x_{J^{i}}$ with $J^{i} \in \Sigma^{\left(k-k_{1}\right)}$ or equal to 0 . Thus, for $x=u_{1} \cdots u_{k_{1}} x_{i} x_{J_{k_{1}+1}}$ with $i \notin K$, the equality (12) holds by induction assumption, and it also holds for $x=u_{1} \cdots u_{k_{1}} u_{k_{1}+1} x_{J_{k_{1}+1}}$ by linearity.

Case b). General case. We need the following
Lemma 4.3. For $K \in \Sigma^{\left(k-k_{1}\right)}$ with $k_{1} \geq 1$, the composition homomorphism $M_{K \mathbb{Q}} \subset$ $M_{\mathbb{Q}} \rightarrow E_{\mathbb{Q}}^{*}$ is surjective.

The proof will be given later. By this lemma, there exists an element $u \in M_{K \mathbb{Q}}$ such that

$$
\left\langle u_{k_{1}+1}, v_{E, J}\right\rangle=\left\langle u, v_{E, J}\right\rangle \text { for all } J \in \Sigma^{(k)}
$$

Note that $\left\langle\iota_{J}^{*}(u), v_{E, J}\right\rangle=\left\langle u, v_{E, J}\right\rangle$ for any $u \in M_{\mathbb{Q}}$. Then, in (12) for $x=u_{1} \cdots$ $u_{k_{1}} u_{k_{1}+1} x_{J_{k_{1}+1}}$ with $J_{k_{1}+1} \in \Sigma^{\left(k-\left(k_{1}+1\right)\right)}$, we have

$$
\begin{aligned}
\iota_{J}^{*}(x)\left(v_{E, J}\right) & =\left(\prod_{i=1}^{k_{1}}\left\langle u_{i}, v_{E, J}\right\rangle\right)\left\langle u_{k_{1}+1}, v_{E, J}\right\rangle \\
& =\left(\prod_{i=1}^{k_{1}}\left\langle u_{i}, v_{E, J}\right\rangle\right)\left\langle u, v_{E, J}\right\rangle
\end{aligned}
$$

Hence if we put $x^{\prime}=u_{1} \cdots u_{k_{1}} u x_{J_{k_{1}+1}}$, the right hand side of (12) is equal to

$$
\sum_{J \in \Sigma^{(k)}} \frac{\iota_{J}^{*}\left(x^{\prime}\right)}{\prod_{j \in J} u_{j}^{J}}\left(v_{E, J}\right) p_{*}\left(e^{\xi} x_{J}\right) .
$$

This last expression is equal to $p_{*}\left(e^{\xi} x^{\prime}\right)$ since $x^{\prime}$ belongs to Case a). Furthermore $p_{*}\left(e^{\xi} x^{\prime}\right)=0$ and $p_{*}\left(e^{\xi} x\right)=0$ by Note after Lemma 4.2. Thus both side of (12) for $x=u_{1} \cdots u_{k_{1}} u_{k_{1}+1} x_{J_{k_{1}+1}}$ are equal to 0 . This completes the proof of Theorem except for the proof of Lemma 4.3.

Proof of Lemma 4.3. Take a simplex $I \in \Sigma^{(n)}$ which contains $K$ and a simplex $K^{\prime} \in \Sigma^{(k-1)}$ such that $K \subset K^{\prime} \subset I$. Such a $K^{\prime}$ exists since $k-k_{1} \leq k-1$. Then there are exactly $n-k+1$ simplices $J^{1}, \ldots, J^{n-k+1} \in \Sigma^{(k)}$ such that $K^{\prime} \subset J^{i} \subset I$. It is easy to see that the vectors $v_{E, J^{1}}, \ldots, v_{E, J^{n-k+1}}$ are linearly independent so that they span $E_{\mathbb{Q}}$. Moreover $M_{K^{\prime} \mathbb{Q}}$ detects these vectors, that is, $M_{K^{\prime} \mathbb{Q}} \rightarrow M_{\mathbb{Q}} \rightarrow E_{\mathbb{Q}}^{*}$ is surjective. Since $M_{K}^{\prime} \subset M_{K} \subset M, M_{K \mathbb{Q}} \rightarrow E_{\mathbb{Q}}^{*}$ is surjective.

Proof of Corollay 3.2. By Proposition 2.3

$$
\#(\mathcal{P}(\nu \xi))=p_{*}\left(e^{\nu \xi} \mathcal{T}_{T}(\Delta, \mathcal{V})\right)=\sum_{k=0}^{n} a_{k}(\xi) \nu^{n-k}
$$

Put $x=\left(\mathcal{T}_{T}(\Delta, \mathcal{V})\right)_{k} \in H_{T}^{2 k}(\Delta, \mathcal{V})_{\mathbb{Q}}$. By Theorem 3.1 and Proposition 2.4

$$
a_{k}(\xi)=\sum_{J \in \Sigma^{(k)}} v^{*}\left(\frac{f^{J}(x)}{f^{J}\left(x_{J}\right)}\right) \frac{\operatorname{vol} \mathcal{P}(\xi)_{J}}{\left|H_{J, \mathcal{V}}\right|}
$$

Thus it suffices to show that

$$
\frac{f^{J}(x)}{f^{J}\left(x_{J}\right)}=\left(\sum_{h \in H_{J, v}} \prod_{j \in J} \frac{1}{1-\chi\left(u_{j}^{J}, h\right) e^{-f^{J}\left(x_{j}\right)}}\right)_{0}
$$

or

$$
f^{J}(x)=\left(\sum_{h \in H_{J, v}} \prod_{j \in J} \frac{f^{J}\left(x_{j}\right)}{1-\chi\left(u_{j}^{J}, h\right) e^{-f^{J}\left(x_{j}\right)}}\right)_{k} .
$$

Let $g \in G_{\Delta}$. If $g \notin G_{J}$, then there is an element $i \notin J$ such that $\chi_{i}(g) \neq 1$, and, for such $i$,

$$
f^{J}\left(\frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}\right)=f^{J}\left(\left(1-\chi_{i}(g)\right)^{-1} x_{i}+\text { higher degree terms }\right)=0
$$

since $f^{J}\left(x_{i}\right)=0$. Thus

$$
f^{J}\left(\prod_{i \in \Sigma^{(1)}} \frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}\right)=0
$$

for $g \notin G_{J}$.
If $g \in G_{J}$, then $\chi_{i}(g)=1$ for $i \notin J$. Thus

$$
f^{J}\left(\frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}\right)=f^{J}\left(1+\frac{1}{2} x_{i}+\text { higher degree terms }\right)=1
$$

for $g \in G_{J}, i \notin J$. It follows that

$$
f^{J}\left(\sum_{g \in G_{\Delta}} \prod_{i \in \Sigma^{(1)}} \frac{x_{i}}{1-\chi_{i}(g) e^{-x_{i}}}\right)=\sum_{g \in G_{J}} \prod_{i \in J} \frac{f^{J}\left(x_{i}\right)}{1-\chi_{i}(g) e^{-f^{J}\left(x_{i}\right)}} .
$$

This implies

$$
f^{J}\left(\mathcal{T}_{T}(\Delta, \mathcal{V})_{k}\right)=\left(\sum_{h \in H_{J, V}} \prod_{j \in J} \frac{f^{J}\left(x_{j}\right)}{1-\chi_{J}\left(u_{j}^{J}, h\right) e^{-f^{J}\left(x_{j}\right)}}\right)_{k} .
$$

This finishes the proof of Corollary 3.2.
Proof of Corollary 3.3. Put $x^{\prime}=\sum_{J \in \Sigma^{(k)}} \mu(x, J) x_{J}$. Then

$$
p_{*}\left(e^{\xi} x^{\prime}\right)=\sum_{J \in \Sigma^{(k)}} \mu(x, J) p_{*}\left(e^{\xi} x_{J}\right)=p_{*}\left(e^{\xi} x\right)
$$

by Theorem 3.1. It follows that $p_{*}\left(e^{\xi}\left(x^{\prime}-x\right)\right)=0$. Thus, in order to prove Corollary 3.3, it suffices to show that $p_{*}\left(e^{\xi} y\right)=0, \forall \xi \in H_{T}^{2}(\Delta)_{\mathbb{Q}}$, implies that $p^{*}(y)=$ 0 . By the assumption $\Delta$ is isomorphic to $\Delta_{X}$ where $X$ is a torus orbifold such that $H^{*}(X)_{\mathbb{Q}}$ is generated by $H^{2}(X)_{\mathbb{Q}}$. For such $X$ we know that $H_{T}^{*}(\Delta)_{\mathbb{Q}}=H_{T}^{*}(X)_{\mathbb{Q}}$ and $H^{*}(\Delta)_{\mathbb{Q}}=H^{*}(X)_{\mathbb{Q}}$ by Remark 3.1. In particular $H^{*}(\Delta)_{\mathbb{Q}}$ satisfies the Poincaré duality. It follows that $p_{*}\left(e^{\xi} y\right)=0$ for all $\xi$ implies that $p_{*}(y)=0$.
