# PARAMETER ESTIMATION FOR INFINITE VARIANCE FRACTIONAL ARIMA 

By Piotr S. Kokoszka and Murad S. Taqqu ${ }^{1}$<br>University of Utah and Boston University

#### Abstract

Consider the fractional ARIMA time series with innovations that have infinite variance. This is a finite parameter model which exhibits both long-range dependence (long memory) and high variability. We prove the consistency of an estimator of the unknown parameters which is based on the periodogram and derive its asymptotic distribution. This shows that the results of Mikosch, Gadrich, Klüppelberg and Adler for ARMA time series remain valid for fractional ARIMA with long-range dependence. We also extend the limit theorem for sample autocovariances of infinite variance moving averages developed in Davis and Resnick to moving averages whose coefficients are not absolutely summable.

1. Introduction and main results. This paper is concerned with the estimation of the parameters of the fractional ARIMA time series $\left\{X_{n}\right\}$ defined by the equations

$$
\begin{equation*}
\Phi(B) X_{n}=\Theta(B) \Delta^{-d} Z_{n}, \tag{1.1}
\end{equation*}
$$

where the innovations $Z_{n}$ have infinite variance and where $d$ is a positive fractional number. $B$ and $\Delta$ denote the backward and differencing operator, respectively. Because of the presence of the fractional $d$, the time series (1.1) has not only infinite variance, but also exhibits long-range dependence (long memory). For more details, see [24], [19] and [20].

Our goal is to estimate both $d$ and the coefficients of the polynomials $\Phi$ and $\Theta$, by using a variant of Whittle's method. For a stationary Gaussian time series with spectral density $g(\lambda, \beta),-\pi<\lambda<\pi$, Whittle's method, which provides an estimate of $\beta$, requires replacing the inverse covariance matrix that appears in the Gaussian likelihood by a Toeplitz (covariance) matrix with spectral density $1 / g$ and then maximizing the quadratic form. Hannan [15] applied Whittle's method to finite variance ARMA time series, that is, to (1.1) with $d=0$. He proved that the estimator is consistent and asymptotically normal. An ARMA time series, however, has short range dependence because the correlations decrease exponentially fast. Fox and Gaqqu [12] extended this result to Gaussian time series with long-range dependence such as fractional Gaussian noise or fractional ARIMA by appealing to a central limit theorem for weighted quadratic forms whose weights

[^0]are chosen in such a way as to compensate for the long-range dependence. Fox and Taqqu's result, which was later generalized to the full maximum likelihood by Dahlhaus [8], is the basis of one of the most commonly used techniques for estimating the intensity of long-range dependence in Gaussian time series (see [2]). Giraitis and Surgailis [13] extended Fox and Taqqu's result to finite variance innovations without Gaussian assumptions and Heyde and Gay [17] to random fields.

When the innovations are in the domain of attraction of an infinite variance stable random variable, covariances stop making sense. One can, however, still use the same estimator as in the Gaussian case. Doing so has the advantage of not having to determine beforehand the often unknown distributions of the innovations. It is necessary, however, to verify that these estimators have good properties in the infinite variance case as well. Mikosch, Gadrich, Klüppelberg and Adler to showed that this is the case for ARMA time series. In this paper we extend the result of Mikosch, Gadrich, Klüppelberg and Adler to fractional ARIMA time series which have long-range dependence. We prove that the estimator is consistent and determine its asymptotic distribution. Because of the slow decay of the coefficients in the fractional ARIMA time series, very few of the technical arguments used by Mikosch, Gadrich, Klüppelberg and Adler [21] carry over to our setting and hence significantly different proofs of the basic lemmas had to be developed.

Assume then that the innovations $Z_{n}$ in (1.1) are i.i.d. with mean zero and are in the domain of attraction of an $\alpha$-stable law with $1<\alpha<2$, that is,

$$
\begin{equation*}
P\left(\left|Z_{n}\right|>x\right)=x^{-\alpha} L(x) \quad \text { as } x \rightarrow \infty, \tag{1.2}
\end{equation*}
$$

where $L$ is a slowly varying function, and

$$
\begin{equation*}
P\left(Z_{n}>x\right) / P\left(\left|Z_{n}\right|>x\right) \rightarrow a, \quad P\left(Z_{n}<-x\right) / P\left(\left|Z_{n}\right|>x\right) \rightarrow b, \tag{1.3}
\end{equation*}
$$

where $a$ and $b$ are nonnegative numbers satisfying $a+b=1$. It has been shown by Kokoszka [18] (and Kokoszka and Taqqu [19] in the case of stable innovations) that for the $Z_{n}$ as above, there is a unique moving average

$$
\begin{equation*}
X_{n}=\sum_{j=0}^{\infty} c_{j} Z_{n-j} \tag{1.4}
\end{equation*}
$$

satisfying (1.1), provided that the polynomials $\Phi$ and $\Theta$ have no zeros in the closed unit disk $D=\{z:|z| \leq 1\}$ and no zeros in common and that $d<1-$ $1 / \alpha$. (This is why we suppose $\alpha$ greater than 1.) The coefficients $c_{j}$ in (1.4) are defined by

$$
\begin{equation*}
\sum_{j=0}^{\infty} c_{j} z^{j}=\frac{\Theta(z)}{\Phi(z)(1-z)^{d}}, \quad|z|<1, \tag{1.5}
\end{equation*}
$$

and are asymptotically proportional to $j^{d-1}$ as $j \rightarrow \infty$. Therefore, they do not
satisfy the fundamental assumption

$$
\begin{equation*}
\sum_{j=0}^{\infty} j\left|c_{j}\right|^{1 \wedge \mu}<\infty \quad \text { for some } 0<\mu<\alpha \tag{1.6}
\end{equation*}
$$

of Mikosch, Gadrich, Klüppelberg and Adler [21]. The fact that the $c_{j}$ 's are not absolutely summable turns out to be a major source of difficulties.

We want to estimate the $(p+q+1)$-dimensional vector

$$
\beta_{0}=\left(\phi_{1}, \ldots, \phi_{p}, \theta_{1}, \ldots, \theta_{q}, d\right)
$$

where $\phi_{1}, \ldots, \phi_{p}$ and $\theta_{1}, \ldots, \theta_{q}$ are the coefficients of the autoregressive polynomial $\Phi(z)=1-\phi_{1} z-\cdots-\phi_{p} z^{p}$ and the moving average polynomial $\Theta(z)=1+\theta_{1} z+\cdots+\theta_{q} z^{q}$, respectively, and $d$ is the differencing parameter in (1.1). We assume that the true value of $d$ is positive and hence lies in the open interval $(0,1-1 / \alpha)$. In the case of Gaussian innovations, positive $d$ corresponds to a spectral density that diverges at zero ( $1 / \mathrm{f}$ noise). The preceding discussion motivates the choice of our parameter space $E$, namely, a compact set contained in

$$
\begin{aligned}
& \left\{\left(\phi_{1}, \ldots, \phi_{p}, \theta_{1}, \ldots, \theta_{q}, d\right): \phi_{p} \neq 0, \theta_{q} \neq 0, \Phi(z) \text { and } \Theta(z)\right. \text { have no } \\
& \left.\quad \text { common zeros, } \Phi(z) \Theta(z) \neq 0 \text { for }|z| \leq 1, d \in\left(0,1-\frac{1}{\alpha}\right)\right\}
\end{aligned}
$$

We introduce now some additional notation which will be used throughout the paper. The time series (1.4), called fractional ARIMA, will be referred to as FARIMA $(p, d, q)$. The elements of $E$ are denoted $\beta$, possibly with some sub- and/or superscripts. The last coordinate of the vector $\beta$ is the difference parameter $d$. The true value of the parameter vector is denoted $\beta_{0}$. The sample autocovariance and autocorrelation functions are defined, respectively, by

$$
\begin{equation*}
\gamma_{n}(h)=\frac{1}{n} \sum_{t=1}^{n-|h|} X_{t} X_{t+|h|} \tag{1.7}
\end{equation*}
$$

and

$$
\begin{equation*}
\rho_{n}(h)=\left(\sum_{t=1}^{n} X_{t}^{2}\right)^{-1}\left(\sum_{t=1}^{n-|h|} X_{t} X_{t+|h|}\right)=\left(\gamma_{n}(0)\right)^{-1} \gamma_{n}(h) \tag{1.8}
\end{equation*}
$$

We will frequently use the corresponding deterministic quantities

$$
\begin{equation*}
\gamma(h)=\sum_{j=0}^{\infty} c_{j} c_{j+|h|}, \quad \rho(h)=(\gamma(0))^{-1} \gamma(h) . \tag{1.9}
\end{equation*}
$$

The normalized periodogram is defined as

$$
\begin{align*}
\tilde{I}_{n}(\lambda) & =\left(\sum_{t=1}^{n} X_{t}^{2}\right)^{-1}\left|\sum_{t=1}^{n} X_{t} e^{-i \lambda t}\right|^{2}  \tag{1.10}\\
& =\sum_{|h|<n} \rho_{n}(h) e^{-i \lambda h}, \quad-\pi \leq \lambda \leq \pi .
\end{align*}
$$

For $\beta \in E$, the power transfer function is

$$
\begin{equation*}
g(\lambda, \beta)=\left|\frac{\Theta\left(e^{-i \lambda}, \beta\right)}{\Phi\left(e^{-i \lambda}, \beta\right)\left(1-e^{-i \lambda}\right)^{d(\beta)}}\right|^{2}=\left|\sum_{j=0}^{\infty} c_{j}(\beta) e^{-i \lambda j}\right|^{2} . \tag{1.11}
\end{equation*}
$$

Following Fox and Taqqu [12], who consider Gaussian fractional ARIMA, and Mikosch, Gadrich, Klüppelberg and Adler [21], who study infinite variance ARMA processes, we define the estimator $\beta_{n}$ based on the sample $X_{1}, \ldots, X_{n}$ as the value of $\beta$ minimizing

$$
\begin{equation*}
\sigma_{n}^{2}(\beta)=\int_{-\pi}^{\pi} \frac{\tilde{I}_{n}(\lambda)}{g(\lambda, \beta)} d \lambda, \quad \beta \in E . \tag{1.12}
\end{equation*}
$$

Notice that under our assumptions, the function $1 / g(\cdot, \cdot)$ is continuous on [ $-\pi, \pi] \times E$ and, hence, in particular, the integral in (1.12) is well defined. The following consistency result holds:

Theorem 1.1. If $\beta_{0}$ is the true parameter and $\beta_{n}$ is the value of $\beta$ minimizing $\sigma_{n}^{2}(\beta)$, then

$$
\begin{equation*}
\beta_{n} \rightarrow_{P} \beta_{0} \tag{1.13}
\end{equation*}
$$

and

$$
\begin{equation*}
\sigma_{n}^{2}\left(\beta_{n}\right) \rightarrow_{P} \frac{2 \pi}{\gamma(0)} . \tag{1.14}
\end{equation*}
$$

This theorem is proved in Section 2.2. As part of the proof, we extend the limit theorem for sample autocovariances of infinite variance moving averages developed in Davis and Resnick [9] to moving averages whose coefficients are not absolutely summable.

We now turn to the asymptotic distribution of the estimator $\beta_{n}$. Theorem 1.2, which generalizes Theorem 2.2 of Mikosch, Gadrich, Klüppelberg and Adler [21] and which is an infinite variance analog of Theorem 2 of Fox and Taqqu [12], is valid under a more restrictive assumption on the innovations $Z_{n}$. We now assume that the $Z_{n}$ are symmetric and are in the domain of normal attraction of a $S \alpha S$ law, that is,

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{j=1}^{n} Z_{j} \rightarrow_{\mathscr{O}} Y \tag{1.15}
\end{equation*}
$$

where $E \exp (i \theta Y)=\exp \left\{-\sigma^{\alpha}|\theta|^{\alpha}\right\}$. Relation (1.15) is equivalent to (see, e.g.,

Gnedenko and Kolmogorov [14])

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty} \lambda^{\alpha} P(Z<-\lambda)=\frac{C_{\alpha} \sigma^{\alpha}}{2} \quad \text { and } \quad \lim _{\lambda \rightarrow \infty} \lambda^{\alpha} P(Z>\lambda)=\frac{C_{\alpha} \sigma^{\alpha}}{2} \tag{1.16}
\end{equation*}
$$

where

$$
\begin{align*}
C_{\alpha} & =\left(\alpha \int_{0}^{\infty}(1-\cos x) \frac{d x}{x^{\alpha+1}}\right)^{-1} \\
& = \begin{cases}\frac{1-\alpha}{\Gamma(2-\alpha) \cos (\pi \alpha / 2)}, & \text { if } \alpha \neq 1 \\
\frac{2}{\pi}, & \text { if } \alpha=1\end{cases} \tag{1.17}
\end{align*}
$$

We make these additional assumptions on the $Z_{n}$ because our proofs depend heavily on the results of Rosinski and Woyczynski [23], which require that the $Z_{n}$ (the $X_{i}$ in their paper) be symmetric and satisfy $\lim \sup _{\lambda \rightarrow \infty} \lambda^{\alpha} P\left(\left|Z_{n}\right|>\lambda\right) \leq$ $C<\infty$.

In order to state our result, we introduce the $(p+q+1) \times(p+q+1)$ matrix $W\left(\beta_{0}\right)$ with entries

$$
\begin{align*}
& w_{i j}=\int_{-\pi}^{\pi} g\left(\lambda, \beta_{0}\right) \frac{\partial^{2}}{\partial \beta_{i} \partial \beta_{j}} g^{-1}\left(\lambda, \beta_{0}\right) d \lambda  \tag{1.18}\\
& i, j=1, \ldots, p+q+1
\end{align*}
$$

and the $(p+q+1)$-dimensional vectors $b_{k}, k \in \mathbb{Z}$, whose $j$ th coordinate is

$$
\begin{align*}
&\left(b_{k}\right)_{j}=\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i k \lambda} g\left(\lambda, \beta_{0}\right) \frac{\partial}{\partial \beta_{j}} g^{-1}\left(\lambda, \beta_{0}\right) d \lambda  \tag{1.19}\\
& j=1, \ldots, p+q+1
\end{align*}
$$

The following theorem shows that, as in the Gaussian case, the asymptotic result for $d=0$ extends to $d>0$.

THEOREM 1.2. If the innovations $Z_{n}$ are symmetric and satisfy

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty} \lambda^{\alpha} P(|Z|>\lambda)=C_{\alpha} \sigma^{\alpha} \tag{1.20}
\end{equation*}
$$

then

$$
\begin{equation*}
\left(\frac{n}{\log n}\right)^{1 / \alpha}\left(\beta_{n}-\beta_{0}\right) \rightarrow_{\mathscr{D}} 4 \pi W^{-1}\left(\beta_{0}\right) \sum_{k=1}^{\infty} \frac{Y_{k}}{Y_{0}} b_{k} \tag{1.21}
\end{equation*}
$$

where $Y_{0}$ is positive $\alpha / 2$-stable with scale parameter $C_{\alpha / 2}^{-2}{ }^{\alpha}$ and the $Y_{k}, k \geq 1$ are i.i.d. $S \alpha S$ with scale parameter $C_{\alpha}^{a / \alpha}$. The random variables $Y_{0}, Y_{1}, Y_{2}, \ldots$ are independent and $C_{\alpha}$ is given in (1.17).

Setting $c_{k}=4 \pi W^{-1}\left(\beta_{0}\right) b_{k}$, observe that the $j$ th coordinate of the limiting random vector $\sum_{k=1}^{\infty} c_{k} Y_{k} / Y_{0}$ is distributed as $\left(\sum_{k=1}^{\infty} \mid\left(c_{k}\right)_{j}{ }^{\alpha}\right)^{1 / \alpha} Y_{1} / Y_{0}$, that is, as the ratio of two independent stable random variables. Observe also that the result is similar to the one in the ARMA case (see [21], Theorem 2.2. In that theorem, the scale parameter of $Y_{k}, k \geq 1$, should be $C_{\alpha}^{-1 / \alpha}$ and not $C_{\alpha}^{1 / \alpha}$ ).

Theorem 1.2 is a first step in the development of statistical procedures for time series that exhibit both infinite variance and long-range dependence. Its proof is presented in Section 3. In Section 4 we describe the results of a small simulation study.
2. Consistency of the estimator. The proof of the consistency Theorem 1.1, which is presented in Section 2.1, follows, in its main outline, that of Theorem 2.1 of Mikosch, Gadrich, Klüppelberg and Adler [21]. In our case, however, the power transfer function $g\left(\lambda, \beta_{0}\right)$ diverges to infinity at $\lambda=0$, so the arguments developed for continuous $g$ do not carry over. By working with the compact parameter space $E$, we are able to avoid some technical complications.

We first establish the following extension of Theorem 4.2 of Davis and Resnick [9].

Theorem 2.1. Suppose the inovations $Z_{n}$ have mean zero and satisfy (1.2) and (1.3) and

$$
\begin{equation*}
\sum_{j=0}^{\infty}\left|c_{j}\right|^{\alpha-\varepsilon}<\infty \tag{2.1}
\end{equation*}
$$

for some $\varepsilon>0$. Then, for the moving average

$$
X_{n}=\sum_{j=0}^{\infty} c_{j} Z_{n-j}
$$

we have

$$
\begin{equation*}
\left(a_{n}^{-2} \sum_{t=1}^{n-|h|} X_{t} X_{t+|h|},|h|<m\right) \rightarrow_{\mathscr{D}}\left(\left(\sum_{j=0}^{\infty} c_{j} c_{j+|h|}\right) Y_{0},|h|<m\right), \tag{2.2}
\end{equation*}
$$

where $Y_{0}$ is as in Theorem 1.2 and the $a_{n}$ are determined by the condition

$$
\begin{equation*}
\forall x>0 \quad \lim _{n \rightarrow \infty} n P\left(\left|Z_{1}\right|>a_{n} x\right)=x^{-\alpha} . \tag{2.3}
\end{equation*}
$$

Observe that in Theorem 2.1 we do not assume the absolute summability of the $c_{j}$ if $\alpha>1$, which was a global assumption in the paper by Davis and Resnick [9]. A careful study of their proofs shows that the result depends on the relation

$$
\begin{equation*}
\lim _{t \rightarrow \infty} \frac{P\left(\left|\sum_{j=0}^{\infty} c_{j} Z_{j}\right|>t\right)}{P\left(\left|Z_{1}\right|>t\right)}=\sum_{j=0}^{\infty}\left|c_{j}\right|^{\alpha} \tag{2.4}
\end{equation*}
$$

and on condition (2.1), which guarantees that the process $X_{n}$ is well defined (see, e.g., [1]). Relation (2.4) was proved by Cline [7] under the assumption that $\sum_{j=0}^{\infty}\left|c_{j}\right|<\infty$ if $\alpha>1$. Because the coefficients $c_{j}$ in the moving average representation of fractional ARIMA processes behave like $j^{d-1}$ as $j \rightarrow \infty$, they are not absolutely summable if $d>0$, and hence we cannot use Cline's result here. We will show, however, that (2.4) continues to hold under condition (2.1) if the $Z_{j}$ have mean zero. As this fact is of central importance to the present paper and is also of independent interest, we formulate it as a separate theorem.

Theorem 2.2. Suppose $1<\alpha<2$ and the $Z_{n}$ have mean zero and satisfy (1.2) and (1.3). Then condition (2.1) implies relation (2.4).

The preceding discussion and Theorem 2.2 imply Theorem 2.1.
The proof of Theorem 2.2, which utilizes the ideas of the proof of Lemma 4.2 of Resnick [22], is given below. (The theorem holds, with the same proof, for two-sided moving averages.)
2.1. Proof of Theorem 2.2. We start by describing the basic idea. While our argument essentially follows the one presented in [22], pages 228-230, the crucial difference is that in order to find an effective upper bound for

$$
\left.P\left(\mid \sum_{j} c_{j} Z_{j} 1_{\left[\left|Z_{j \mid}\right| \leq x\left|c_{j}\right|\right.}{ }^{-1}\right] \mid>x\right),
$$

we use the Chebyshev inequality rather than the Markov inequality. This makes it unnecessary to use Jensen's inequality to reduce the case $\alpha \geq 1$ to the case $\alpha<1$, a procedure which required the assumption $\sum_{j}\left|c_{j}\right|<\infty$ ( $\sum_{j}$ stands for $\sum_{j=0}^{\infty}$ or $\sum_{j=-\infty}^{\infty}$ ). Observe first that

$$
\begin{aligned}
P\left(\left|\sum_{j} c_{j} Z_{j}\right|>x\right)= & P\left(\left|\sum_{j} c_{j} Z_{j}\right|>x, \sup _{j}\left|c_{j} Z_{j}\right|>x\right) \\
& +P\left(\left|\sum_{j} c_{j} Z_{j}\right|>x, \sup _{j}\left|c_{j} Z_{j}\right| \leq x\right) \\
\leq & P\left(\bigcup_{j}\left\{\left|c_{j} Z_{j}\right|>x\right\}\right)+P\left(\left|\sum_{j} c_{j} Z_{j} 1_{\left[\mid c_{j} Z_{j \mid \leq x]}\right.}\right|>x\right) \\
\leq & \sum_{j} P\left(\left|Z_{j}\right|>x\left|c_{j}\right|^{-1}\right)+x^{-2} E\left|\sum_{j} c_{j} Z_{j} 1_{\left[\left|Z_{j}\right| \leq x\left|c_{j}\right|^{-1}\right]}\right|^{2} .
\end{aligned}
$$

We first verify that the series $\sum_{j} Y_{j}, Y_{j}=c_{j} Z_{j} 1_{\left[\mid c_{j} Z_{j \mid \leq x]}\right.}$ converges in $L^{2}$. Observe that the $Y_{j}$ need not be orthogonal. It suffices to show that $\sum_{j}\left|E Y_{j}\right|<\infty$ and $\sum_{j} E\left|Y_{j}-E Y_{j}\right|^{2}<\infty$. In the arguments below we often use Potter's theorem (see Theorem 1.5.6(c) of Bingham, Goldie and Teugels [4]). Since $E Z_{j}=0$,
we have for sufficiently large $j$,

$$
\begin{align*}
\left|E Y_{j}\right| & =\left|E\left\{c_{j} Z_{j} 1_{\left[\left|c_{j} Z_{j}\right|>x\right]}\right\}\right| \\
& \leq \int_{0}^{x} P\left(\left|c_{j} Z_{j}\right|>x\right) d t+\int_{x}^{\infty} P\left(\left|c_{j} Z_{j}\right|>t\right) d t \\
& \leq x(1+\varepsilon) x^{-\alpha+\varepsilon}\left|c_{j}\right|^{\alpha-\varepsilon}+(1+\varepsilon)\left|c_{j}\right|^{\alpha-\varepsilon} \int_{x}^{\infty} t^{-\alpha+\varepsilon} d t  \tag{2.6}\\
& =(1+\varepsilon) \frac{\alpha-\varepsilon}{\alpha-1-\varepsilon} x^{1-\alpha+\varepsilon}\left|c_{j}\right|^{\alpha-\varepsilon},
\end{align*}
$$

which shows that the series $\sum_{j} E Y_{j}$ converges absolutely. Since $\sum_{j} E\left|Y_{j}-E Y_{j}\right|^{2} \leq$ $\sum_{j} E Y_{j}^{2}$, it remains to verify that $\sum_{j} E Y_{j}^{2}<\infty$. It follows from the well-known relation

$$
\begin{equation*}
\frac{E\left[Z_{1}^{2} 1_{\left[\left|Z_{1}\right| \leq x\right]}\right]}{x^{2} P\left(\left|Z_{1}\right|>x\right)} \rightarrow \frac{\alpha}{2-\alpha} \tag{2.7}
\end{equation*}
$$

(see Section 8.1 of Bingham, Goldie and Teugels [4]) that the function $U(x):=E\left[\left|Z_{1}\right|^{2} 1_{\left[\mid Z_{1 \mid \leq x]}\right]}\right]$ is regularly varying with index $2-\alpha$ and, consequently, for sufficiently large $x$ and some constant $K$,

$$
\begin{aligned}
\frac{E Y_{j}^{2}}{x^{2} P\left(\left|Z_{1}\right|>x\right)} & =\left|c_{j}\right|^{2} \frac{E\left[Z_{1}^{2} 1_{\left[\left|Z_{1}\right| \leq x\left|c_{j}\right|-1\right]}\right]}{x^{2} P\left(\left|Z_{1}\right|>x\right)} \\
& =\left|c_{j}\right|^{2} \frac{U\left(x\left|c_{j}\right|^{-1}\right)}{U(x)} \frac{U(x)}{x^{2} P\left(\left|Z_{1}\right|>x\right)} \\
& \leq K\left|c_{j}\right|^{2}\left(\left|c_{j}\right|^{-1}\right)^{2-\alpha+\varepsilon}=K\left|c_{j}\right|^{\alpha-\varepsilon} .
\end{aligned}
$$

Since $E\left|\Sigma_{j} Y_{j}\right|^{2}=\operatorname{Var}\left(\Sigma Y_{j}\right)+\left(E \Sigma Y_{j}\right)^{2} \leq \Sigma_{j} E Y_{j}^{2}+\left(\Sigma_{j}\left|E Y_{j}\right|\right)^{2}$, we obtain from (2.5), (2.6) and (2.8),

$$
\begin{equation*}
\frac{P\left(\left|\sum_{j} c_{j} Z_{j}\right|>x\right)}{P\left(\left|Z_{1}\right|>x\right)} \leq S_{1}(x)+S_{2}(x)+S_{3}(x) \tag{2.9}
\end{equation*}
$$

where

$$
\begin{aligned}
& S_{1}(x)=\sum_{j} \frac{P\left(\left|Z_{1}\right|>x\left|c_{j}\right|^{-1}\right)}{P\left(\left|Z_{1}\right|>x\right)}, \\
& S_{2}(x)=\sum_{j} \frac{E Y_{j}^{2}}{x^{2} P\left(\left|Z_{1}\right|>x\right)}, \\
& S_{3}(x)=\frac{\left(\sum_{j}\left|E Y_{j}\right|\right)^{2}}{x^{2} P\left(\left|Z_{1}\right|>x\right)}
\end{aligned}
$$

Since $P\left(\left|Z_{1}\right|>x\right)$ is regularly varying at infinity with index $-\alpha$, for sufficiently large $j$ the summands in the sum defining $S_{1}(x)$ do not exceed
$(1+\varepsilon)\left|c_{j}\right|^{\alpha-\varepsilon}$, and so $\lim _{x \rightarrow \infty} S_{1}(x)=\sum_{j}\left|c_{j}\right|^{\alpha}$. By (2.7), (2.8) and the dominated convergence theorem, $\lim _{x \rightarrow \infty} S_{2}(x)=\alpha /(2-\alpha) \sum_{j}\left|c_{j}\right|^{\alpha}$. Finally, by (2.6), $S_{3}(x) \leq c(\alpha, \varepsilon)\left(\sum_{j}\left|c_{j}\right|^{\alpha-\varepsilon}\right)^{2} x^{-\alpha+\varepsilon}$. The inequality (2.9) and these relations yield

$$
\begin{equation*}
\limsup _{x \rightarrow \infty} \frac{P\left(\left|\Sigma_{j} c_{j} Z_{j}\right|>x\right)}{P\left(\left|Z_{1}\right|>x\right)} \leq \frac{2}{2-\alpha} \sum_{j}\left|c_{j}\right|^{\alpha} . \tag{2.10}
\end{equation*}
$$

Now, for any $0<r<1$ and any positive integer $m$,

$$
P\left(\left|\sum_{j} c_{j} Z_{j}\right|>x\right) \geq P\left(\left|\sum_{|j| \leq m} c_{j} Z_{j}\right|>(1+r) x\right)-P\left(\left|\sum_{|j|>m} c_{j} Z_{j}\right|>r x\right) .
$$

Since the hypothesis of the theorem holds for finite sums (see the proposition on page 278 of Feller [11]), (2.10) yields

$$
\begin{align*}
& \liminf _{x \rightarrow \infty} \frac{P\left(\left|\sum_{j} c_{j} Z_{j}\right|>x\right)}{P\left(\left|Z_{1}\right|>x\right)} \\
& \quad \geq(1+r)^{-\alpha} \sum_{|j| \leq m}\left|c_{j}\right|^{\alpha}-\frac{2}{(2-\alpha) r^{\alpha}} \sum_{|j|>m}\left|c_{j}\right|^{\alpha} . \tag{2.11}
\end{align*}
$$

Similarly,

$$
\begin{align*}
& \limsup _{x \rightarrow \infty} \frac{P\left(\left|\sum_{j} c_{j} Z_{j}\right|>x\right)}{P\left(\left|Z_{1}\right|>x\right)} \\
& \quad \leq(1-r)^{-\alpha} \sum_{|j| \leq m}\left|c_{j}\right|^{\alpha}+\frac{2}{(2-\alpha) r^{\alpha}} \sum_{|j|>m}\left|c_{j}\right|^{\alpha} . \tag{2.12}
\end{align*}
$$

Letting first $m \rightarrow \infty$ and then $r \rightarrow 0$ in (2.11) and (2.12), we get (2.4).
2.2. Proof of the consistency Theorem 1.1. The proof of Theorem 1.1 uses two lemmas. The first extends Proposition 10.8.1 of Brockwell and Davis [5]; the second extends Lemma 1 of Fox and Taqqu [12] and Lemma 6.1 of Mikosch, Gadrich, Klüppelberg and Adler [21].

Lemma 2.1. Suppose $\beta_{1}, \beta_{2} \in E$. If $\beta_{1} \neq \beta_{2}$, then

$$
\begin{equation*}
\frac{1}{2 \pi} \int_{-\pi}^{\pi} \frac{g\left(\lambda, \beta_{1}\right)}{g\left(\lambda, \beta_{2}\right)} d \lambda>1 \tag{2.13}
\end{equation*}
$$

Proof. For $|z|<1$ and $\beta \in E$ define

$$
\begin{aligned}
& C(z, \beta)=\frac{\Theta(z, \beta)}{\Phi(z, \beta)(1-z)^{d(\beta)}}=\sum_{j=0}^{\infty} c_{j}(\beta) z^{j}, \\
& H(z, \beta)=\frac{1}{C(z, \beta)}=\sum_{j=0}^{\infty} h_{j}(\beta) z^{j} .
\end{aligned}
$$

Let $\left\{\varepsilon_{n}\right\}$ be a sequence of i.i.d. $N(0,1)$ random variables and consider the Gaussian fractional ARIMA process

$$
X_{n}\left(\beta_{1}\right)=\sum_{j=0}^{\infty} c_{j}\left(\beta_{1}\right) \varepsilon_{n-j} .
$$

It is well known (see, e.g, Brockwell and Davis [5], Section 13.2) that $\operatorname{Var}\left(X_{n+1}\left(\beta_{1}\right)-\sum_{j=0}^{\infty} u_{j} X_{n-j}\left(\beta_{1}\right)\right)$ is minimized if and only if $u_{j}=-h_{j+1}\left(\beta_{1}\right)$ and the minimum value of the variance is 1 . Since $\beta_{2} \neq \beta_{1}$, we have $H\left(\cdot, \beta_{2}\right.$ ) $\neq H\left(\cdot, \beta_{1}\right)$, and so $\operatorname{Var}\left(X_{n+1}\left(\beta_{1}\right)+\sum_{j=0}^{\infty} h_{j+1}\left(\beta_{2}\right) X_{n-j}\left(\beta_{1}\right)\right)>1$. This concludes the proof because that variance equals

$$
\begin{aligned}
\sum_{j=0}^{\infty}\left|\sum_{k=0}^{j} h_{k}\left(\beta_{2}\right) c_{j-k}\left(\beta_{1}\right)\right|^{2} & =\frac{1}{2 \pi} \int_{-\pi}^{\pi}\left|H\left(e^{-i \lambda}, \beta_{2}\right) C\left(e^{-i \lambda}, \beta_{1}\right)\right|^{2} d \lambda \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi}\left|\frac{C\left(e^{-i \lambda}, \beta_{1}\right)}{C\left(e^{-i \lambda}, \beta_{2}\right)}\right|^{2} d \lambda \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi} \frac{g\left(\lambda, \beta_{1}\right)}{g\left(\lambda, \beta_{2}\right)} d \lambda .
\end{aligned}
$$

Remark. The lemma holds whenever $|d|<\frac{1}{2}$, thus not only for positive values of $d$. Indeed, since for $d<\frac{1}{2}, C\left(e^{-i}, \beta\right) \in L^{2}[-\pi, \pi]$ and for $d>-\frac{1}{2}$, $H\left(e^{-i}, \beta\right) \in L^{2}[\pi, \pi]$, Parseval's relation applies whenever $|d|<1 / 2$.

Lemma 2.2. Let $f(\lambda, \beta)$ be any continuous (and hence uniformly continuous) function on $[-\pi, \pi] \times E$. Then, as $n \rightarrow \infty$,

$$
\begin{align*}
\sup _{\beta \in E} & \mid \int_{-\pi}^{\pi} f(\lambda, \beta) \tilde{I}_{n}(\lambda) d \lambda \\
& \left.-\frac{1}{\gamma(0)} \int_{-\pi}^{\pi} f(\lambda, \beta) g\left(\lambda, \beta_{0}\right) d \lambda \right\rvert\, \rightarrow_{P} 0 . \tag{2.14}
\end{align*}
$$

Proof. The proof is similar to the proof of Lemma 6.1 of Mikosch, Gadrich, Klüppelberg and Adler [21]. Note, however, that for fractional ARIMA processes the function $g\left(\lambda, \beta_{0}\right)$ diverges at $\lambda=0$.

Let $K_{m}\left(e^{i \lambda}\right)=\sum_{|h|<m}(1-|h| / m) e^{i \lambda h}$ denote the Fejér kernel. Fix $\varepsilon>0$ and choose $m$ so large that for all $\lambda$ and $\beta$,

$$
\begin{equation*}
\left|K_{m} * f(\lambda, \beta)-f(\lambda, \beta)\right|<\frac{\varepsilon}{4 \pi} \tag{2.15}
\end{equation*}
$$

[To verify (2.15), repeat the proof of Fejér's theorem for continuous functions and use the uniform continuity of $f$ in both variables.] Hence, for any $\beta$,

$$
\left|\int_{-\pi}^{\pi} f(\lambda, \beta) \tilde{I}_{n}(\lambda) d \lambda-\int_{-\pi}^{\pi} K_{m} * f(\lambda, \beta) \tilde{I}_{n}(\lambda) d \lambda\right|<\frac{\varepsilon}{4 \pi} \int_{-\pi}^{\pi} \tilde{I}_{n}(\lambda) d \lambda=\frac{\varepsilon}{2} .
$$

Consequently,

$$
\begin{aligned}
& P\left(\sup _{\beta}\left|\int_{-\pi}^{\pi} f(\lambda, \beta) \tilde{I}_{n}(\lambda) d \lambda-\gamma(0)^{-1} \int_{-\pi}^{\pi} f(\lambda, \beta) g\left(\lambda, \beta_{0}\right) d \lambda\right| \geq \varepsilon\right) \\
& \leq P\left(\sup _{\beta} \mid \int_{-\pi}^{\pi} K_{m} * f(\lambda, \beta) \tilde{I}_{n}(\lambda) d \lambda\right. \\
& \left.16) \quad-\gamma(0)^{-1} \int_{-\pi}^{\pi} f(\lambda, \beta) g\left(\lambda, \beta_{0}\right) d \lambda \left\lvert\, \geq \frac{\varepsilon}{2}\right.\right) \\
& =P\left(\sup _{\beta} \left\lvert\, 2 \pi \sum_{|h|<m}\left(1-\frac{|h|}{m}\right) \hat{f}(h, \beta) \rho_{n}(h)\right.\right. \\
& \left.\quad-\gamma(0)^{-1} \int_{-\pi}^{\pi} f(\lambda, \beta) g\left(\lambda, \beta_{0}\right) d \lambda \left\lvert\, \geq \frac{\varepsilon}{2}\right.\right)
\end{aligned}
$$

where $\rho_{n}(h)$ is given in (1.8) and $\hat{f}(h, \beta)=(1 / 2 \pi) \int_{-\pi}^{\pi} e^{-i h \lambda} f(\lambda, \beta) d \lambda$. The last quantity in (2.16) is bounded above by

$$
\begin{align*}
& P\left(\sup _{\beta}\left|2 \pi \sum_{|h|<m}\left(\rho_{n}(h)-\rho(h)\right)\left(1-\frac{|h|}{m}\right) \hat{f}(h, \beta)\right| \geq \frac{\varepsilon}{4}\right) \\
&+P\left(\sup _{\beta} \left\lvert\, 2 \pi \sum_{|h|<m} \rho(h)\left(1-\frac{|h|}{m}\right) \hat{f}(h, \beta)\right.\right.  \tag{2.17}\\
&\left.\quad \gamma(0)^{-1} \int_{-\pi}^{\pi} f(\lambda, \beta) g\left(\lambda, \beta_{0}\right) d \lambda \left\lvert\, \geq \frac{\varepsilon}{4}\right.\right) .
\end{align*}
$$

The first term in (2.17) tends to zero because, by Theorem 2.1, $\rho_{n}(h) \rightarrow_{\mathscr{D}}$ $\rho(h)$ and $|\hat{f}(h, \beta)| \leq \sup _{-\pi \leq \lambda \leq \pi} \sup _{\beta \in E}|f(\lambda, \beta)|<\infty$. To evaluate the second term in (2.17) observe that

$$
\begin{aligned}
& 2 \pi \sum_{|h|<m} \rho(h)\left(1-\frac{|h|}{m}\right) \hat{f}(h, \beta) \\
& \quad=\gamma(0)^{-1} \int_{-\pi}^{\pi}\left[\sum_{|h|<m} \gamma(h)\left(1-\frac{|h|}{m}\right) e^{i \lambda h}\right] f(\lambda, \beta) d \lambda
\end{aligned}
$$

and

$$
\sum_{|h|<m} \gamma(h)\left(1-\frac{|h|}{m}\right) e^{i \lambda h}=K_{m} * g\left(\lambda, \beta_{0}\right) .
$$

Therefore the second term in (2.17) equals

$$
P\left(\sup _{\beta}\left|\gamma(0)^{-1} \int_{-\pi}^{\pi}\left[K_{m} * g\left(\lambda, \beta_{0}\right)-g\left(\lambda, \beta_{0}\right)\right] f(\lambda, \beta) d \lambda\right| \geq \frac{\varepsilon}{4}\right),
$$

which is zero for sufficiently large $m$ because $f(\lambda, \beta)$ is uniformly bounded on $[-\pi, \pi] \times E$ and, by Fejér's theorem (see, e.g., Helson [16], page 14),

$$
\int_{-\pi}^{\pi}\left|K_{m} * g\left(\lambda, \beta_{0}\right)-g\left(\lambda, \beta_{0}\right)\right| d \lambda \rightarrow 0 \quad \text { as } m \rightarrow \infty,
$$

since $g\left(\cdot, \beta_{0}\right) \in L^{1}[-\pi, \pi]$. This concludes the proof.
Proof of the consistency Theorem 1.1. Since $d(\beta)>0$, the function $1 / g(\lambda, \beta)$ is continuous on $[-\pi, \pi] \times E$, and hence Lemma 2.2 applies. We get

$$
\begin{equation*}
\sigma_{n}^{2}=\int_{-\pi}^{\pi} \frac{\tilde{I}_{n}(\lambda)}{g(\lambda, \cdot)} d \lambda \rightarrow_{P} \sigma^{2}:=\frac{1}{\gamma(0)} \int_{-\pi}^{\pi} \frac{g\left(\lambda, \beta_{0}\right)}{g(\lambda, \cdot)} d \lambda, \tag{2.18}
\end{equation*}
$$

where $\sigma_{n}{ }^{2}$ and $\sigma^{2}$ are random elements of the function space $C(E)$ of continuous functions on $E$ equipped with the sup-norm. The remainder of the proof, included for completeness, is a variation on the proof of Theorem 2.1 of Mikosch, Gadrich, Klüppelberg and Adler.

Since $\beta_{0}$ is a constant, to prove (1.13) it suffices to show that $\beta_{n} \rightarrow_{\mathscr{O}} \beta_{0}$. Because $E$ is compact, the sequence $\left\{\beta_{n}\right\}$ is tight, and hence $\beta_{n} \rightarrow_{\mathscr{\mathscr { C }}} \beta_{0}$ if and only if every weakly convergent subsequence of $\left\{\beta_{n}\right\}$ converges weakly to $\beta_{0}$.

Let then $\left\{\beta_{m}\right\}$ be a subsequence of $\left\{\beta_{n}\right\}$ such that $\beta_{m} \rightarrow_{\mathscr{D}} \beta^{\prime}$ ( $\beta^{\prime}$ is a random variable). We want to show that $\beta^{\prime}=\beta_{0}$ a.s.

By (2.18) and Theorem 4.4 of Billingsley [3],

$$
\begin{equation*}
\left(\sigma_{m}^{2}, \beta_{m}\right) \rightarrow_{\mathscr{O}}\left(\sigma^{2}, \beta^{\prime}\right) \quad[\text { in } C(E) \times E], \tag{2.19}
\end{equation*}
$$

since $\sigma^{2}$ is a nonrandom element in $C(E)$. By the continuous mapping theorem, (2.19) implies

$$
\begin{equation*}
\sigma_{m}^{2}\left(\beta_{m}\right) \rightarrow_{\mathscr{O}} \sigma^{2}\left(\beta^{\prime}\right) . \tag{2.20}
\end{equation*}
$$

and hence, for any $t$,

$$
\begin{equation*}
\underset{m}{\lim \sup } P\left(\sigma_{m}^{2}\left(\beta_{m}\right) \leq t\right) \leq P\left(\sigma^{2}\left(\beta^{\prime}\right) \leq t\right) . \tag{2.21}
\end{equation*}
$$

Now, the definition of $\beta_{n}$ and (2.18) yield

$$
\sigma_{m}^{2}\left(\beta_{m}\right) \leq \sigma_{m}^{2}\left(\beta_{0}\right) \rightarrow_{P} t_{0}:=\frac{2 \pi}{\gamma(0)} .
$$

Consequently,

$$
\begin{align*}
& \liminf _{m}^{\operatorname{lin}} P\left(\sigma_{m}^{2}\left(\beta_{m}\right)<t\right)  \tag{2.22}\\
& \quad \geq \liminf _{m} P\left(\sigma_{m}^{2}\left(\beta_{0}\right)<t\right) \geq 1 \quad \forall t>t_{0},
\end{align*}
$$

and so $\lim \sup _{m} P\left(\sigma_{m}^{2}\left(\beta_{m}\right) \leq t\right)=1$ for all $t>t_{0}$. Using (2.21) we obtain

$$
\begin{equation*}
P\left(\sigma^{2}\left(\beta^{\prime}\right) \leq t\right)=1 \quad \forall t>t_{0} . \tag{2.23}
\end{equation*}
$$

Moreover, by Lemma 2.1, $\sigma^{2}\left(\beta^{\prime}\right)>t_{0}$ whenever $\beta^{\prime} \neq \beta_{0}$, and so

$$
\begin{equation*}
\lim _{t \searrow t_{0}} P\left\{\sigma^{2}\left(\beta^{\prime}\right) \leq t, \beta^{\prime} \neq \beta_{0}\right\}=P\left\{\sigma^{2}\left(\beta^{\prime}\right) \leq t_{0}, \beta^{\prime} \neq \beta_{0}\right\}=0 . \tag{2.24}
\end{equation*}
$$

The equality (2.23) implies that for any $t>t_{0}$,

$$
\begin{aligned}
1 & =P\left(\sigma^{2}\left(\beta^{\prime}\right) \leq t, \beta^{\prime}=\beta_{0}\right)+P\left(\sigma^{2}\left(\beta^{\prime}\right) \leq t, \beta^{\prime} \neq \beta_{0}\right) \\
& \leq P\left(\beta^{\prime}=\beta_{0}\right)+P\left(\sigma^{2}\left(\beta^{\prime}\right) \leq t, \beta^{\prime} \neq \beta_{0}\right),
\end{aligned}
$$

which together with (2.24) yields $P\left(\beta^{\prime}=\beta_{0}\right)=1$. This is what we wanted to establish.

Finally, to prove (1.14), write

$$
\begin{align*}
& P\left(\left|\sigma_{n}^{2}\left(\beta_{n}\right)-\sigma^{2}\left(\beta_{0}\right)\right| \geq \varepsilon\right) \\
& \quad \leq P\left(\left|\sigma_{n}^{2}\left(\beta_{n}\right)-\sigma^{2}\left(\beta_{n}\right)\right| \geq \varepsilon / 2\right)  \tag{2.25}\\
& \quad+P\left(\left|\sigma^{2}\left(\beta_{n}\right)-\sigma^{2}\left(\beta_{0}\right)\right| \geq \varepsilon / 2\right) .
\end{align*}
$$

The first term in the right-hand side of (2.25) tends to zero by (2.18), the second because $\beta_{n} \rightarrow_{P} \beta_{0}$ and $\sigma^{2}$ is continuous on $E$.
3. Asymptotic distribution of the estimator. The crucial element in the proof of Theorem 1.2 is Proposition 3.1, which is established in Section 3.2. We show first that this proposition yields Theorem 1.2.

Proposition 3.1. For real numbers $u_{1}, u_{2}, \ldots, u_{p+q+1}$ (which are fixed but arbitrary) set

$$
\begin{equation*}
\eta(\lambda)=\sum_{j=1}^{p+q+1} u_{j} \frac{\partial}{\partial \beta_{j}} g^{-1}\left(\lambda, \beta_{0}\right) . \tag{3.1}
\end{equation*}
$$

Then, as $n \rightarrow \infty$,

$$
\begin{align*}
& \left(\frac{n}{\log n}\right)^{1 / \alpha} \int_{-\pi}^{\pi} \tilde{I}_{n}(\lambda) \eta(\lambda) d \lambda \\
& \quad \rightarrow_{\mathscr{O}} \frac{4 \pi}{\gamma(0)} \sum_{k=1}^{\infty} \frac{Y_{k}}{Y_{0}}\left(\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i k \lambda} g\left(\lambda, \beta_{0}\right) \eta(\lambda) d \lambda\right) \tag{3.2}
\end{align*}
$$

where the random variables $Y_{0}, Y_{1}, Y_{2}$ are as in Theorem 1.2.
Proof of Theorem 1.2. Let $\beta / \partial \beta$ denote the column vector with entries $\partial / \partial \beta_{j}, j=1, \ldots, p+q+1$, and $\partial^{2} / \partial \beta^{2}$ the matrix with entries $\partial^{2} / \partial \beta_{i} \partial \beta_{j}$, $i, j=1, \ldots, p+q+1$. Relation (3.2) implies

$$
\begin{equation*}
\left(\frac{n}{\log n}\right)^{1 / \alpha} \frac{\partial}{\partial \beta} \sigma_{n}^{2}\left(\beta_{0}\right) \rightarrow_{\mathscr{O}} \frac{4 \pi}{\gamma(0)} \sum_{k=1}^{\infty} \frac{Y_{k}}{Y_{0}} b_{k} \tag{3.3}
\end{equation*}
$$

[cf. (1.12)]. Also,

$$
\begin{equation*}
\frac{\partial^{2}}{\partial \beta^{2}} \sigma_{n}^{2}\left(\beta_{0}\right)=\int_{-\pi}^{\pi} \tilde{I}_{n}(\lambda) \frac{\partial^{2}}{\partial \beta^{2}} g^{-1}\left(\lambda, \beta_{0}\right) d \lambda . \tag{3.4}
\end{equation*}
$$

Differentiation under the integral in (3.3) and (3.4) is justified because the function $g(\lambda, \beta)$ is proportional to the spectral density of Gaussian fractional ARIMA and consequently satisfies condition (A3) on page 521 of Fox and Taqqu [12], namely, for any $\delta>0$ there are constants $K_{1}(\delta)$ and $K_{2}(\delta)$ such that

$$
\begin{equation*}
\left|\frac{\partial}{\partial \beta_{j}} g^{-1}(\lambda, \beta)\right| \leq K_{1}(\delta)|\lambda|^{2 d(\beta)-\delta}, \quad j=1, \ldots, p+q+1, \tag{3.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\frac{\partial^{2}}{\partial \beta_{i} \partial \beta_{j}} g^{-1}(\lambda, \beta)\right| \leq K_{2}(\delta)|\lambda|^{2 d(\beta)-\delta}, \quad i, j=1, \ldots, p+q+1 . \tag{3.6}
\end{equation*}
$$

Since $E$ is compact, we can clearly assume that there is a $\delta>0$ such that

$$
\begin{equation*}
\inf _{\beta \in E}(2 d(\beta)-\delta)>0 \tag{3.7}
\end{equation*}
$$

Condition (3.7) together with (3.6) show that $\partial^{2} / \partial \beta^{2}\left(g^{-1}\left(\lambda, \beta_{0}\right)\right)$ has continuous components, and so, by Lemma 2.2 and (3.4),

$$
\begin{equation*}
\sup _{\beta \in E}\left\|\frac{\partial^{2}}{\partial \beta^{2}} \sigma_{n}^{2}(\beta)-\frac{1}{\gamma(0)} W\left(\beta_{0}\right)\right\| \rightarrow_{P} 0 . \tag{3.8}
\end{equation*}
$$

Since $\beta_{n}$ minimizes $\sigma_{n}^{2}(\beta)$, there is some $\beta_{n}^{*}$ satisfying $\left\|\beta_{n}^{*}-\beta_{0}\right\|<\| \beta_{n}-$ $\beta_{0} \|$ such that

$$
\begin{equation*}
\frac{\partial}{\partial \beta} \sigma_{n}^{2}\left(\beta_{0}\right)=-\frac{\partial^{2}}{\partial \beta^{2}} \sigma_{n}^{2}\left(\beta_{n}^{*}\right)\left(\beta_{n}-\beta_{0}\right) . \tag{3.9}
\end{equation*}
$$

Multiplying both sides of (3.9) by $(n / \log n)^{1 / \alpha}$ and using (3.3) and (3.8) together with Theorem 4.4 of Billingsley [3], yields (1.21).
3.1. Tools. We state here several results on which we rely extensively.

The following proposition follows from Theorem 3.1 of Rosinski and Woyczynski [23].

Proposition 3.2. Suppose $Z_{1}, Z_{2}, \ldots$ is a sequence of i.i.d. symmetric random variables satisfying

$$
\begin{equation*}
\limsup _{\lambda \rightarrow \infty} \lambda^{\alpha} P\left(\left|Z_{1}\right|>\lambda\right) \leq C<\infty, \tag{3.10}
\end{equation*}
$$

where $0<\alpha<2$. Consider the sequence of bilinear forms

$$
\begin{equation*}
Q_{n}=\sum_{\substack{j, k=1 \\ j \neq k}}^{n} q(j, k) Z_{j} Z_{k}, \tag{3.11}
\end{equation*}
$$

and set

$$
\begin{equation*}
N_{\alpha}^{(n)}=\sum_{\substack{j, k=1 \\ j \neq k}}^{n}|q(j, k)|^{\alpha}\left(1+\log _{+}|q(j, k)|^{-1}\right) \tag{3.12}
\end{equation*}
$$

Then there is a constant $D_{\alpha}$ such that

$$
\begin{equation*}
P\left(\left|Q_{n}\right|>\lambda\right) \leq D_{\alpha} \lambda^{-\alpha}\left(1+\log _{+} \lambda\right) N_{\alpha}^{(n)} \tag{3.13}
\end{equation*}
$$

Moreover, if $N_{\alpha}=\lim _{n \rightarrow \infty} N_{\alpha}^{(n)}<\infty$, then the sequence $\left\{Q_{n}\right\}$ converges in $L^{p}$, for any $0<p<\alpha$, to the limit

$$
\begin{equation*}
Q=\sum_{\substack{j, k=1 \\ j \neq k}}^{\infty} q(j, k) Z_{j} Z_{k}, \tag{3.14}
\end{equation*}
$$

which satisfies

$$
\begin{equation*}
P(|Q|>\lambda) \leq D_{\alpha} \lambda^{-\alpha}\left(1+\log _{+} \lambda\right) N_{\alpha} \tag{3.15}
\end{equation*}
$$

By $\log _{+} x$ we mean $\log x$ if $x \geq 1$ and 0 otherwise. Combining this proposition with the inequality

$$
\begin{equation*}
x^{\alpha}\left(1+\log _{+} \frac{1}{x}\right)<(\alpha-\mu)^{-1} x^{\mu} \tag{3.16}
\end{equation*}
$$

valid for $1<\mu<\alpha$ and $0<x<1$, we get the following corollary:
Corollary 3.1. Suppose $p$ is a real number. If for some $1<\mu<\alpha$,

$$
\lim _{n \rightarrow \infty} \sum_{\substack{j, k \\ j \neq k}}\left|n^{p} q_{n}(j, k)\right|^{\mu}=0
$$

then

$$
n^{p} \sum_{\substack{j, k \\ j \neq k}} q_{n}(j, k) Z_{j} Z_{k} \rightarrow_{P} 0 \quad \text { as } n \rightarrow \infty
$$

The next proposition is a direct consequence of Theorem 3.3 of Davis and Resnick [10].

Proposition 3.3. Suppose the $Z_{n}$ and the $Y_{k}, k \geq 0$, are as in Theorem 1.2. Then, for any $m>0$, as $n \rightarrow \infty$,

$$
\begin{gather*}
\left(n^{-2 / \alpha} \sum_{t=1}^{n} Z_{t}^{2},(n \log n)^{-1 / \alpha} \sum_{t=1}^{n-1} Z_{t} Z_{t+1}, \ldots\right. \\
\left.(n \log n)^{-1 / \alpha} \sum_{t=1}^{n-m} Z_{t} Z_{t+m}\right)  \tag{3.17}\\
\rightarrow{ }_{\mathscr{O}}\left(C_{\alpha}^{2 / \alpha} \sigma^{2}\right)\left(Y_{0}, Y_{1}, \ldots, Y_{m}\right)
\end{gather*}
$$

We shall use the following lemma often.

Lemma 3.1. Suppose the $c_{j}$ are defined by (1.5). Then for $0<|\lambda|<\pi$ and any integers $n_{1}<n_{2}$,

$$
\begin{equation*}
\left|\sum_{j=n_{1}}^{n_{2}} c_{j} e^{i \lambda j}\right| \leq K n_{1}^{d-1}|\lambda|^{-1} \tag{3.18}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\sum_{j=n_{1}}^{n_{2}} c_{j} e^{i \lambda j}\right| \leq K|\lambda|^{-d}, \tag{3.19}
\end{equation*}
$$

where $K$ does not depend on $n_{1}, n_{2}$ and $\lambda$.
Proof. Inequality (3.18) follows immediately from the fact that $\lim _{j \rightarrow \infty} c_{j} / j^{d-1}$ exists (cf. Bingham, Goldie and Teugels [4], page 208). Inequality (3.19) can be proved by modifying slightly the proof of Theorem 2.6 and using inequalities 2.26 and 2.27 on page 191 of Zygmund [25].
3.2. Proof of Proposition 3.1. Proposition 3.1 follows from a number of lemmas which are proved below, some of which are of independent interest.

Lemma 3.2. Consider the function $\eta$ defined in Proposition 3.1 and set

$$
\chi(\lambda)=\eta(\lambda) g\left(\lambda, \beta_{0}\right)
$$

and

$$
f_{k}=\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i \lambda k} \chi(\lambda) d \lambda .
$$

Then $f_{k}=O\left(|k|^{-1}\right)$ as $k \rightarrow \infty$.
Proof. By (1.11),

$$
\begin{aligned}
\chi(\lambda) & =\left(\sum_{j=1}^{p+q=1} u_{j} \frac{\partial g^{-1}\left(\lambda, \beta_{0}\right)}{\partial \beta_{j}}\right) g\left(\lambda, \beta_{0}\right) \\
& =-\sum_{j=1}^{p+q+1} u_{j} \frac{\partial}{\partial \beta_{j}} \log g\left(\lambda, \beta_{0}\right) \\
& =-\sum_{j=1}^{p+q+1} u_{j} \frac{\partial}{\partial \beta_{j}}\left\{\log \left|\frac{\Theta\left(e^{-i \lambda}, \beta_{0}\right)}{\Phi\left(e^{-i \lambda}, \beta_{0}\right)}\right|^{2}-2 d\left(\beta_{0}\right) \log \left|1-e^{-i \lambda}\right|\right\} .
\end{aligned}
$$

Thus, we can write

$$
\begin{equation*}
\chi(\lambda)=\chi_{1}(\lambda)+A\left(\beta_{0}\right) \log \left|2 \sin \frac{\lambda}{2}\right|, \tag{3.20}
\end{equation*}
$$

where

$$
\begin{equation*}
\chi_{1}(\lambda)=-\sum_{j=1}^{p+q+1} u_{j} \frac{\partial}{\partial \beta_{j}} \log \left|\frac{\Theta\left(e^{-i \lambda}, \beta_{0}\right)}{\Phi\left(e^{-i \lambda}, \beta_{0}\right)}\right|^{2} \tag{3.21}
\end{equation*}
$$

and

$$
\begin{equation*}
A\left(\beta_{0}\right)=2 \sum_{j=0}^{p+q+1} u_{j} \frac{\partial}{\partial \beta_{j}} d\left(\beta_{0}\right) . \tag{3.22}
\end{equation*}
$$

By (3.20), $f_{k}=f_{1 k}+A\left(\beta_{0}\right) f_{2 k}$, where $f_{1 k}$ is the Fourier coefficient of $\chi_{1}$ and

$$
\begin{equation*}
f_{2 k}=\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i \lambda k} \log \left|2 \sin \frac{\lambda}{2}\right| d \lambda . \tag{3.23}
\end{equation*}
$$

As the function $\chi_{1}$ has continuous derivative on $[-\pi, \pi]$, we have $f_{1 k}=$ $O\left(|k|^{-1}\right)$ and so it remains to show that $f_{2 k}=O\left(|k|^{-1}\right)$. Integrating the righthand side of (3.23) by parts and setting $\lambda=2 \mu$, we get

$$
\begin{equation*}
f_{2 k}=-\frac{1}{\pi k} \int_{0}^{\pi / 2} \frac{\sin (2 k \mu) \cos \mu}{\sin \mu} d \mu . \tag{3.24}
\end{equation*}
$$

Consequently, we must show that the integrals

$$
I_{j}=\int_{0}^{\pi / 2} \frac{\sin (j \mu) \cos \mu}{\sin \mu} d \mu
$$

are uniformly bounded in $j$. To verify this, decompose $I_{j}$ as $I_{j}=I_{1 j}+I_{2 j}$, where

$$
I_{1 j}=\int_{0}^{\pi / 2} \frac{\sin (j \mu) \cos \mu}{\mu} d \mu
$$

and

$$
I_{2 j}=\int_{0}^{\pi / 2} \sin (j \mu) \cos \mu\left(\frac{1}{\sin \mu}-\frac{1}{\mu}\right) d \mu .
$$

Since $|1 / \sin \mu-1 / \mu|=O(\mu)$, as $\mu \rightarrow 0$, the sequence $\left\{I_{2 j}\right\}$ is bounded. To see that the sequence $\left\{I_{1 j}\right\}$ is bounded, observe that

$$
I_{1 j}=\frac{1}{2}\left\{\int_{0}^{\pi / 2} \frac{\sin (j+1) \mu}{\mu} d \mu+\int_{0}^{\pi / 2} \frac{\sin (j-1) \mu}{\mu} d \mu\right\}
$$

and

$$
\int_{0}^{\pi / 2} \frac{\sin (j \mu)}{\mu} d \mu=\int_{0}^{\pi j / 2} \frac{\sin x}{x} d x \rightarrow \int_{0}^{\infty} \frac{\sin x}{x} d x
$$

as $j \rightarrow \infty$, the last integral converging conditionally.
Lemma 3.2 is used in the proof of Proposition 3.4, in which $\tilde{I}_{n, Z}(\lambda)$ denotes the self-normalized periodogram of the process $\left\{Z_{t}\right\}$, that is,

$$
\begin{equation*}
\tilde{I}_{n, Z}(\lambda)=\left(\sum_{t=1}^{n} Z_{t}^{2}\right)^{-1}\left|\sum_{t=1}^{n} Z_{t} e^{-i \lambda t}\right|^{2} . \tag{3.25}
\end{equation*}
$$

Proposition 3.4. Suppose the $Z_{n}$ and the $Y_{k}, k \geq 0$, are as in Theorem 1.2 and the function $\chi$ and the sequence $\left\{f_{k}\right\}$ are as in Lemma 3.2. Then

$$
\begin{equation*}
\left(\frac{n}{\log n}\right)^{1 / \alpha} \int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda) \chi(\lambda) d \lambda \rightarrow_{\mathscr{D}} 4 \pi \sum_{k=1}^{\infty} \frac{Y_{k}}{Y_{0}} f_{k} \tag{3.26}
\end{equation*}
$$

as $n \rightarrow \infty$.
Proof. This proof follows closely that of Lemma 6.3 of Mikosch, Gadrich, Klüppelberg and Adler [21]. We use here $\alpha>1$ and Lemma 3.2 rather than the assumption $\sum\left|f_{k}\right|^{\mu}<\infty$ for some $\mu \in(0,1 \wedge \alpha)$, which holds in the ARMA case.

By Theorem 4.2 of Billingsley [3], relation (3.26) will follow, once we have verified that, as $m \rightarrow \infty$,

$$
\begin{equation*}
2 \pi \sum_{|k| \leq m} \frac{Y_{k}}{Y_{0}} f_{k} \rightarrow_{P} 4 \pi \sum_{k=1}^{\infty} \frac{Y_{k}}{Y_{0}} f_{k} \tag{3.27}
\end{equation*}
$$

and, as $n \rightarrow \infty$,

$$
\begin{equation*}
\left(\frac{n}{\log n}\right)^{1 / \alpha} \int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda) \chi_{m}(\lambda) d \lambda \rightarrow_{\mathscr{D}} 2 \pi \sum_{|k| \leq m} \frac{Y_{k}}{Y_{0}} f_{k} \tag{3.28}
\end{equation*}
$$

for each fixed $m$, where $\chi_{m}(\lambda)=\sum_{|k| \leq m} f_{k} e^{i \lambda k}$ and

$$
\begin{align*}
& \lim _{m \rightarrow \infty} \limsup _{n \rightarrow \infty} P\left\{\left(\frac{n}{\log n}\right)^{1 / \alpha}\left|\int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda)\left(\chi(\lambda)-\chi_{m}(\lambda)\right) d \lambda\right|>\varepsilon\right\}  \tag{3.29}\\
& \quad=0
\end{align*}
$$

for any $\varepsilon>0$.
In order to verify (3.27) observe first that

$$
\begin{equation*}
\int_{-\pi}^{\pi} \log g(\lambda, \beta) d \lambda=0 \quad \forall \beta \in E \tag{3.30}
\end{equation*}
$$

Relation (3.30) follows from the remark on page 520 of Fox and Taqqu [12] and the fact that $g(\lambda, \beta)=2 \pi f(\lambda, \beta)$, where $f(\lambda, \beta)$ is the spectral density of the Gaussian fractional ARIMA. Using condition (A.1) of Fox and Taqqu [12] with $g$ in place of $f$, we get, by (3.30),

$$
\begin{aligned}
f_{0} & =\sum_{j=1}^{p+q+1} u_{j} \frac{1}{2 \pi} \int_{-\pi}^{\pi} \frac{\partial}{\partial \beta_{j}} \log g^{-1}\left(\lambda, \beta_{0}\right) d \lambda \\
& =\sum_{j=1}^{p+q+1} u_{j} \frac{\partial}{\partial \beta_{j}}\left(-\frac{1}{2 \pi} \int_{-\pi}^{\pi} \log g\left(\lambda, \beta_{0}\right) d \lambda\right)=0
\end{aligned}
$$

In view of the above relation and the fact that $f_{k}=f_{-k}$, it remains to show that

$$
\begin{equation*}
\sum_{|k|>m} \frac{Y_{k}}{Y_{0}} f_{k} \rightarrow_{P} 0 \quad \text { as } m \rightarrow \infty . \tag{3.31}
\end{equation*}
$$

Since $Y_{0}$ is independent of the remaining $Y_{k}$ 's, it suffices to verify that $\sum_{|k|>m} f_{k} Y_{k} \rightarrow_{P} 0$. The latter relation follows from the three series theorem and Lemma 3.2.

Direct verification, moreover, shows that

$$
\begin{aligned}
& \left(\frac{n}{\log n}\right)^{1 / \alpha} \int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda) \chi_{m}(\lambda) d \lambda \\
& \quad=2 \pi\left(n^{-2 / \alpha} \sum_{t=1}^{n} Z_{t}^{2}\right)^{-1} \sum_{|k| \leq m} f_{k}\left[(n \log n)^{-1 / \alpha} \sum_{t=1}^{n-|k|} Z_{t} Z_{t+|k|}\right]
\end{aligned}
$$

so relation (3.28) follows from Proposition 3.3.
Finally, to verify (3.29), notice that for $m<n$,

$$
\begin{align*}
\int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda)\left(\chi(\lambda)-\chi_{m}(\lambda)\right) d \lambda & =\int_{-\pi}^{\pi}\left(\sum_{|h|<n} \rho_{n, Z}(h) e^{-i \lambda h}\right)\left(\sum_{|k|>m} f_{k} e^{i \lambda k}\right) d \lambda \\
& =\sum_{|h|<n} \rho_{n, Z}(h) \int_{-\pi}^{\pi}\left(\sum_{|k|>m} f_{k} e^{i \lambda(k-h)}\right) d \lambda  \tag{3.32}\\
& =2 \pi \sum_{m<|h|<n} \rho_{n, Z}(h) f_{h},
\end{align*}
$$

where

$$
\begin{equation*}
\rho_{n, Z}(h)=\left(\sum_{t=1}^{n} Z_{t}^{2}\right)^{-1}\left(\sum_{t=1}^{n-|h|} Z_{t} Z_{t+h}\right) . \tag{3.33}
\end{equation*}
$$

[The last equality in (3.32) is justified by the fact that $\sum_{|k|>m}\left|f_{k}\right|^{2}<\infty$.] Equalities (3.32) and (3.33) and a change of indices yield

$$
\begin{align*}
& \left(\frac{n}{\log n}\right)^{1 / \alpha} \int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda)\left(\chi(\lambda)-\chi_{m}(\lambda)\right) d \lambda \\
& \quad=4 \pi\left(n^{-2 / \alpha} \sum_{t=1}^{n} Z_{t}^{2}\right)^{-1}(n \log n)^{-1 / \alpha} \sum_{t=1}^{n-m-1} Z_{t} \sum_{h=m+t+1}^{n} f_{h-t} Z_{h} . \tag{3.34}
\end{align*}
$$

By Proposition 3.3, $n^{-2 / \alpha} \sum_{t=0}^{n} Z_{t}^{2} \rightarrow_{\mathscr{D}} Y_{0}$, so (3.28) will follow once we have verified that

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \limsup _{n \rightarrow \infty} P\left\{(n \log n)^{-1 / \alpha}\left|\sum_{t=1}^{n-m-1} Z_{t} \sum_{h=m+t+1}^{n} f_{h-t} Z_{h}\right|>\varepsilon\right\}=0 . \tag{3.35}
\end{equation*}
$$

By (3.13) and the inequality (3.16), the probability in (3.35) is bounded above by

$$
\begin{equation*}
K_{\alpha, \mu} \varepsilon^{-\alpha} n^{-1} \sum_{t=1}^{n-m-1} \sum_{h=m+t+1}^{h}\left|f_{h-t}\right|^{\mu} . \tag{3.36}
\end{equation*}
$$

Since, by Lemma 3.2,

$$
n^{-1} \sum_{t=1}^{n-m-1} \sum_{h=m+t+1}^{n}\left|f_{h-t}\right|^{\mu} \leq n^{-1} \sum_{t=1}^{n} \sum_{j=m+1}^{\infty}\left|f_{j}\right|^{\mu} \leq K m^{1-\mu},
$$

we see that (3.35) holds.
Our next goal is to establish a relationship between the right-hand side of (3.2) and the right-hand side of (3.26). The first step in this direction is to relate the sample variances of the processes $\left\{X_{t}\right\}$ and $\left\{Z_{t}\right\}$.

Lemma 3.3. Suppose the $Z_{n}, c_{j}, X_{n}$ and $a_{n}$ are as in Theorem 2.1. Then

$$
\begin{equation*}
a_{n}^{-2} \sum_{k=1}^{n} X_{k}^{2}=\left(\sum_{j=0}^{\infty} c_{j}^{2}\right) a_{n}^{-2} \sum_{k=1}^{n} Z_{k}^{2}\left(1+o_{P}(1)\right) . \tag{3.37}
\end{equation*}
$$

Proof. We only sketch the proof since it is similar to the proofs in Davis and Resnick [9,10] which rely on point processes techniques. Let

$$
\lambda(d x)=\alpha p x^{-\alpha-1} \mathbf{1}_{(0, \infty)}(x) d x+\alpha q(-x)^{-\alpha-1} \mathbf{1}_{(-\infty, 0)}(x) d x
$$

be the Lévy measure of a stable random variable and set $\mu(d t, d x)=d t \times$ $\lambda(d x), t>0$, where $d t$ stands for the Lebesgue measure. If $\sum_{k=1}^{\infty} \varepsilon_{\left(t_{k}, j_{k}\right)}$ is the Poisson random measure with mean measure $\mu$, then Theorem 2.2 of Davis and Resnick [9] asserts that

$$
\begin{equation*}
\sum_{k=1}^{\infty} \varepsilon_{\left(k / n, a_{n}^{-1} \mathbf{Z}^{(k)}\right)} \Rightarrow \sum_{k=1}^{\infty} \sum_{i=1}^{m} \varepsilon_{\left(t_{k}, j_{k} \mathbf{e}_{i}\right)}, \tag{3.38}
\end{equation*}
$$

where $\Rightarrow$ denotes the weak convergence of random measures on $(0, \infty) \times$ $\mathbb{R}^{m} \backslash\{0, \ldots, 0\}, \mathbf{Z}^{(k)}=\left(Z_{k}, Z_{k-1}, \ldots, Z_{k-m+1}\right)$ and where $\mathbf{e}_{i} \in \mathbb{R}^{m}$ is the basis element with $i$ th component equal to 1 and the rest 0 . Instead of applying, as in Davis and Resnick [9], the continuous map $\left(z_{k}, z_{k-1}, \ldots, z_{k-m+1}\right) \mapsto$ $\sum_{i=0}^{m-1} c_{i} z_{k-i}$ to both sides of (3.38), we shall apply the continuous map $\left(z_{k}, z_{k-1}, \ldots, z_{k-m+1}\right) \mapsto\left(\sum_{i=0}^{m-1} c_{i} z_{k-i}, z_{k}\right)$. Thus using Theorems 4.2 and 5.1 of Billingsley [3] and the arguments of the proof of Theorem 2.4 of Davis and Resnick, we get

$$
\begin{equation*}
\sum_{k=1}^{n} \varepsilon_{\left(a_{n}^{-1}\left(X_{k}, Z_{k}\right)\right)} \Rightarrow \sum_{k=1}^{\infty}\left(\varepsilon_{\left(c_{o} j_{k}, j_{k}\right)}+\sum_{i=1}^{\infty} \varepsilon_{\left(c_{i} j_{k}, 0\right)}\right) \tag{3.39}
\end{equation*}
$$

where now the space is $\left.\mathbb{R}^{2} \backslash\{0\} 0,\right\}$. Proceeding as in the proof of Theorem 4.2
of Davis and Resnick [9], it can be verified that (3.39) yields

$$
\begin{equation*}
a_{n}^{-2} \sum_{k=1}^{n}\left(X_{k}^{2}, Z_{k}^{2}\right) \rightarrow_{\mathscr{O}}\left(\sum_{j=0}^{\infty} c_{j}^{2}, 1\right) S, \tag{3.40}
\end{equation*}
$$

where the $\alpha / 2$-stable random variable $S$ is as in Theorem 2.1. Finally, applying the continuous map $h(u, v)=\left(u-\left(\sum_{j=0}^{\infty} c_{j}^{2}\right) v\right) / v$ to both sides of (3.40), we obtain (3.37).

Remark. Lemma 3.3 extends Lemma 5.2 of Mikosch, Gadrich, Klüppelberg and Adler, which was proved under the assumption (1.6). We have shown that condition (2.1) is sufficient for (3.37) to hold.

Lemma 3.3 yields the following useful corollary:
Corollary 3.2. For any fractional ARIMA process whose innovations satisfy (1.2) and (1.3),

$$
\begin{align*}
& \int_{-\pi}^{\pi} \tilde{I}_{n}(\lambda) \eta(\lambda) d \lambda \\
& \quad=\gamma(0)^{-1}\left(1+o_{P}(1)\right) \int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda) g\left(\lambda, \beta_{0}\right) \eta(\lambda) d \lambda  \tag{3.41}\\
& \quad+\gamma(0)^{-1}\left(1+o_{P}(1)\right)\left(a_{n}^{-2} \sum_{k=1}^{n} Z_{k}^{2}\right)^{-1} \int_{-\pi}^{\pi} R_{n}(\lambda) \eta(\lambda) d \lambda,
\end{align*}
$$

where $\gamma(0)=\sum_{j=0}^{\infty} c_{j}^{2}$ and

$$
\begin{align*}
R_{n}(\lambda)= & \left|Y_{n}(\lambda)\right|^{2}+Y_{n}(\lambda)\left(\sum_{j=0}^{\infty} c_{j} e^{i \lambda j}\right)\left(a_{n}^{-1} \sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right) \\
& +Y_{n}(-\lambda)\left(\sum_{j=0}^{\infty} c_{j} e^{-i \lambda j}\right)\left(a_{n}^{-1} \sum_{k=1}^{n} Z_{k} e^{-i \lambda k}\right) \tag{3.42}
\end{align*}
$$

and where

$$
\begin{equation*}
Y_{n}(\lambda)=a_{n}^{-1} \sum_{j=0}^{\infty} c_{j} e^{-i \lambda j}\left(\sum_{k=1-j}^{n-j} Z_{k} e^{-i \lambda k}-\sum_{k=1}^{n} Z_{k} e^{-i \lambda k}\right) . \tag{3.43}
\end{equation*}
$$

Proof. Defining

$$
I_{n, X}(\lambda)=\frac{1}{a_{n}^{2}}\left|\sum_{t=1}^{n} X_{t} e^{-i \lambda t}\right|^{2} \quad \text { and } \quad I_{n, Z}(\lambda)=\frac{1}{a_{n}^{2}}\left|\sum_{t=1}^{n} Z_{t} e^{-i \lambda t}\right|^{2},
$$

it can be verified identically as in the case of finite variance ARMA processes (cf., e.g., the proof of Theorem 10.3.1 of Brockwell and Davis [5]) that

$$
\begin{equation*}
I_{n, X}(\lambda)=\left|\sum_{j=0}^{\infty} c_{j} e^{-i \lambda j}\right|^{2} I_{n, Z}(\lambda)+R_{n}(\lambda) . \tag{3.44}
\end{equation*}
$$

Now, using Lemma 3.3, we have

$$
\begin{aligned}
\int_{-\pi}^{\pi} \tilde{I}_{n}(\lambda) \eta(\lambda) d \lambda= & \int_{-\pi}^{\pi}\left(\sum_{k=1}^{n} X_{k}^{2}\right)^{-1}\left|\sum_{k=1}^{n} X_{k} e^{-i \lambda k}\right|^{2} \eta(\lambda) d \lambda \\
= & \left(a_{n}^{-2} \sum_{k=1}^{n} X_{k}^{2}\right)^{-1} \int_{-\pi}^{\pi} I_{n, X}(\lambda) \eta(\lambda) d \lambda \\
= & {\left[\gamma(0) a_{n}^{-2} \sum_{k=1}^{n} Z_{k}^{2}\left(1+o_{P}(1)\right)\right]^{-1} } \\
& \times \int_{-\pi}^{\pi}\left[g\left(\lambda, \beta_{0}\right) I_{n, Z}(\lambda)+R_{n}(\lambda)\right] \eta(\lambda) d \lambda \\
= & \gamma(0)^{-1}\left(1+o_{P}(1)\right) \int_{-\pi}^{\pi} \tilde{I}_{n, Z}(\lambda) g\left(\lambda, \beta_{0}\right) \eta(\lambda) d \lambda \\
& +\gamma(0)^{-1}\left(1+o_{P}(1)\right)\left(a_{n}^{-2} \sum_{k=1}^{n} Z_{k}^{2}\right)^{-1} \int_{-\pi}^{\pi} R_{n}(\lambda) \eta(\lambda) d \lambda .
\end{aligned}
$$

Since $g\left(\lambda, \beta_{0}\right) \eta(\lambda)=\chi(\lambda)$ and $a_{n}^{-2} \sum_{k=1}^{n} Z_{k}^{2} \rightarrow_{\mathscr{D}} S$, by (3.40), we obtain the following corollary.

Corollary 3.3. The relation

$$
\begin{equation*}
\left(\frac{n}{\log n}\right)^{1 / \alpha} \int_{-\pi}^{\pi} R_{n}(\lambda) \eta(\lambda) d \lambda \rightarrow_{P} 0 \quad \text { as } n \rightarrow \infty \tag{3.45}
\end{equation*}
$$

together with Proposition 3.4 will imply relation (3.2) and hence will complete the proof of Proposition 3.1.

Therefore, it remains to establish (3.45). In view of (3.42) and the fact that under the assumptions of Theorem 1.2, $a_{n}$ is proportional to $n^{1 / \alpha}$, relation (3.45) will follow once we have proved the following two lemmas:

Lemma 3.4. Setting $Y_{n}(\lambda)=a_{n}^{-1} \Delta_{n}(\lambda)$, we have

$$
\begin{equation*}
(n \log n)^{-1 / \alpha} \int_{-\pi}^{\pi}\left|\Delta_{n}(\lambda)\right|^{2} \eta(\lambda) d \lambda \rightarrow_{P} 0 \quad \text { as } n \rightarrow \infty . \tag{3.46}
\end{equation*}
$$

Lemma 3.5. Setting $C(\lambda):=\sum_{j=0}^{\infty} c_{j} e^{i \lambda j}$, we have

$$
\begin{align*}
& (n \log n)^{-1 / \alpha} \int_{-\pi}^{\pi} \Delta_{n}(\lambda) C(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right) \eta(\lambda) d \lambda  \tag{3.47}\\
& \quad \rightarrow_{P} 0 \quad \text { as } n \rightarrow \infty
\end{align*}
$$

The proof of these lemmas involves delicate bounds where the assumption $0<d<1-1 / \alpha$ plays a crucial role.

### 3.3. Proof of the two lemmas.

Proof of Lemma 3.4. We show that

$$
\begin{equation*}
n^{-1 / \alpha} \int_{-\pi}^{\pi}\left|\Delta_{n}(\lambda)\right|^{2} \eta(\lambda) d \lambda \rightarrow_{P} 0 . \tag{3.48}
\end{equation*}
$$

Observe that $\Delta_{n}(\lambda)$ can be conveniently split into four sums as follows:

$$
\begin{align*}
\Delta_{n}(\lambda) & =\sum_{j=0}^{\infty} c_{j} e^{-i \lambda j}\left[\sum_{k=1-j}^{n-j} Z_{k} e^{-i \lambda k}-\sum_{k=1}^{n} Z_{k} e^{-i \lambda k}\right]  \tag{3.49}\\
& =\Gamma_{1 n}(\lambda)+\Gamma_{2 n}(\lambda)+\Gamma_{3 n}(\lambda)+\Gamma_{4 n}(\lambda),
\end{align*}
$$

where

$$
\begin{align*}
& \Gamma_{1 n}(\lambda)=\sum_{k=0}^{n-2}\left(\sum_{j=k+1}^{n+k} c_{j} e^{i(k-j) \lambda}\right) Z_{-k},  \tag{3.50}\\
& \Gamma_{2 n}(\lambda)=\sum_{k=n-1}^{\infty}\left(\sum_{j=k+1}^{n+k} c_{j} e^{i(k-j) \lambda}\right) Z_{-k},  \tag{3.51}\\
& \Gamma_{3 n}(\lambda)=-e^{-i n \lambda} \sum_{k=0}^{n-2}\left(\sum_{j=k+1}^{n-1} c_{j} e^{i(k-j) \lambda}\right) Z_{n-k},  \tag{3.52}\\
& \Gamma_{4 n}(\lambda)=-\left(\sum_{j=n}^{\infty} c_{j} e^{-i \lambda j}\right) \sum_{t=1}^{n} Z_{t} e^{-i \lambda t} . \tag{3.53}
\end{align*}
$$

Clearly, (3.48) will follow once we have verified that

$$
\begin{equation*}
n^{-1 / \alpha} \int_{-\pi}^{\pi}\left|\Gamma_{u n}(\lambda)\right|^{2}|\eta(\lambda)| d \lambda \rightarrow_{P} 0 \tag{3.54}
\end{equation*}
$$

for $u=1,2,3,4$.
Step 1 . We first verify (3.54) with $u=1$. Write

$$
\begin{aligned}
& \int_{-\pi}^{\pi}\left|\Gamma_{1 n}(\lambda)\right|^{2}|\eta(\lambda)| d \lambda \\
& \quad= \\
& \quad \sum_{t=0}^{n-2} Z_{-t}^{2}\left(\int_{-\pi}^{\pi}\left|\sum_{j=t+1}^{n+t} c_{j} e^{i \lambda j}\right|^{2}|\eta(\lambda)| d \lambda\right) \\
& \\
& \quad+\sum_{\substack{t, k=0 \\
t \neq k}}^{n-2} Z_{-t} Z_{-k} \int_{-\pi}^{\pi}\left(\sum_{j=k+1}^{n+k} c_{j} e^{i(k-j) \lambda}\right) \\
& \quad \times\left(\sum_{j=t+1}^{n+t} c_{j} e^{i(j-t) \lambda}\right)|\eta(\lambda)| d \lambda \\
& =
\end{aligned}
$$

In order to establish upper bounds on the coefficients $\nu_{n}(t)$ and $\kappa_{n}(k, t)$, observe that by condition (A.3) on page 521 of Fox and Taqqu [12], for any $\delta>0$,

$$
\begin{equation*}
|\eta(\lambda)|=O\left(|\lambda|^{2 d-\delta}\right) \quad \text { as } \lambda \rightarrow 0 . \tag{3.56}
\end{equation*}
$$

Relation (3.56) and the two inequalities of Lemma 3.1 yield

$$
\begin{equation*}
\left|\nu_{n}(t)\right| \leq K_{1} t^{d-1} \int_{-\pi}^{\pi}|\lambda|^{-d-1+2 d-\delta} d \lambda \leq K_{2} t^{d-1} \tag{3.57}
\end{equation*}
$$

if $\delta$ is small enough. The same argument shows that

$$
\begin{equation*}
\left|\kappa_{n}(k, t)\right| \leq K_{2}(t \vee k)^{d-1} . \tag{3.58}
\end{equation*}
$$

Using (3.57), we obtain, for $1<\mu<\alpha$,

$$
\begin{align*}
P\left\{n^{-1 / \alpha} \sum_{t=0}^{n-2} \nu_{n}(t) Z_{-t}^{2}>\varepsilon\right\} & \leq \varepsilon^{-\mu / 2} n^{-\mu / 2 \alpha} E\left|\sum_{t=0}^{n-2} \nu_{n}(t) Z_{-t}^{2}\right|^{\mu / 2} \\
9) & \leq \varepsilon^{-\mu / 2} n^{-\mu / 2 \alpha} E \sum_{t=0}^{n-2}\left|\nu_{n}(t)\right|^{\mu / 2}\left|Z_{-t}\right|^{\mu}  \tag{3.59}\\
& \leq \varepsilon^{-\mu / 2} E\left|Z_{1}\right|^{\mu} K_{2}^{\mu / 2} n^{-\mu / 2 \alpha} \sum_{t=0}^{n-2} t^{(d-1) \mu / 2} \\
& =O\left(n^{-\mu / 2 \alpha+((d-1) \mu) / 2+1}\right) .
\end{align*}
$$

Observe that the condition $d<1-1 / \alpha$ implies that the exponent $-\mu / 2 \alpha+$ $((d-1) \mu) / 2+1$ is negative for $\mu$ sufficiently close to $\alpha$. Therefore,

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{t=0}^{n-2} \nu_{n}(t) Z_{-t}^{2} \rightarrow_{P} 0 . \tag{3.60}
\end{equation*}
$$

By Corollary 3.1, to show

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{\substack{t, k=1 \\ t \neq k}}^{n-2} \kappa_{n}(k, t) Z_{-t} Z_{-k} \rightarrow_{P} 0 \tag{3.61}
\end{equation*}
$$

it suffices to verify that for some $1<\mu<\alpha$,

$$
\begin{equation*}
\sum_{1 \leq t<k \leq n-2}\left(n^{-1 / \alpha} k^{(d-1)}\right)^{\mu} \rightarrow 0 \quad \text { as } n \rightarrow \infty . \tag{3.62}
\end{equation*}
$$

Note that the left-hand side of (3.62) is bounded above by a multiple of

$$
n^{-\mu / \alpha} \int_{1}^{n}\left(\int_{t}^{n} k^{(d-1) \mu} d k\right) d t=O\left(n^{(d-1) \mu+2-\mu / \alpha}\right),
$$

which tends to 0 as $n \rightarrow \infty$ for $\mu$ sufficiently close to $\alpha$. Indeed if $\mu=\alpha$, the exponent of $n$ becomes $-1+(d-1) \alpha+2=(d-1) \alpha+1$, which is negative since $d<1-1 / \alpha$.

Relations (3.60), (3.61) and (3.55) prove (3.54) with $u=1$.
Step 2 . To verify (3.54) with $u=2$, we must show that

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{t=n-1}^{\infty} \nu_{n}(t) Z_{-t}^{2} \rightarrow_{P} 0 \tag{3.63}
\end{equation*}
$$

and

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{\substack{t, k=n-1 \\ t \neq k}}^{\infty} \kappa_{n}(t, k) Z_{-t} Z_{-k} \rightarrow_{P} 0 \tag{3.64}
\end{equation*}
$$

with the $\nu_{n}(t)$ and the $\kappa_{n}(k, t)$ as in the case $u=1$. Here, however, we need more delicate bounds than (3.57) and (3.58). Write

$$
\left|\kappa_{n}(k, t)\right| \leq 2\left(I_{1}+I_{2}\right),
$$

where

$$
\begin{align*}
& I_{1}=\int_{0}^{\pi / n}\left|\sum_{j=t+1}^{n+t} c_{j} e^{i \lambda j} \| \sum_{j=k+1}^{n+k} c_{j} e^{i \lambda j}\right| \eta(\lambda) \mid d \lambda,  \tag{3.65}\\
& I_{2}=\int_{\pi / n}^{\pi}\left|\sum_{j=t+1}^{n+t} c_{j} e^{i \lambda j}\right| \sum_{j=k+1}^{n+k} c_{j} e^{i \lambda j}| | \eta(\lambda) \mid d \lambda . \tag{3.66}
\end{align*}
$$

Note that by (3.56), for sufficiently small $\delta>0$,

$$
\begin{equation*}
I_{1}=O\left(\int_{0}^{\pi / n} n^{2} t^{d-1} k^{d-1} \lambda^{2 d-\delta} d \lambda\right)=O\left(t^{d-1} k^{d-1} n^{1-2 d+\delta}\right) . \tag{3.67}
\end{equation*}
$$

To establish an upper bound on $I_{2}$, set $x=n \lambda$ in (3.66). Then

$$
\begin{align*}
I_{2} & =O\left(t^{d-1} k^{d-1} n^{1-2 d+\delta} \int_{\pi}^{n \pi} x^{2 d-2-\delta} d x\right)  \tag{3.68}\\
& =O\left(t^{d-1} k^{d-1} n^{1-2 d+\delta}\right) .
\end{align*}
$$

Combining (3.67) and (3.68), we get

$$
\begin{equation*}
\kappa_{n}(k, t)=O\left(t^{d-1} k^{d-1} n^{1-2 d+\delta}\right) \tag{3.69}
\end{equation*}
$$

and, in particular,

$$
\begin{equation*}
\nu_{n}(t)=O\left(t^{2(d-1)} n^{1-2 d+\delta}\right) . \tag{3.70}
\end{equation*}
$$

Now we verify (3.63). By (3.70), for $1<\mu<\alpha$, we have

$$
\begin{align*}
P\left\{n^{-1 / \alpha}\left|\sum_{t=n-1}^{\infty} \nu_{n}(t) Z_{-t}^{2}\right|>\varepsilon\right\} & \leq\left(\varepsilon n^{1 / \alpha}\right)^{-\mu / 2} E\left|\sum_{t=n-1}^{\infty} \nu_{n}(t) Z_{-t}^{2}\right|^{\mu / 2} \\
& \leq K_{n}^{-\mu / 2 \alpha} \sum_{t=n-1}^{\infty}\left(t^{2(d-1)} n^{1-2 d+\delta}\right)^{\mu / 2}  \tag{3.71}\\
& =O\left(n^{-\mu /(2 \alpha)+(d-1) \mu+1+(1-2 d+\delta) \mu / 2}\right)
\end{align*}
$$

Notice that if $\delta=0$, and $\mu=\alpha$, the exponent is equal to $-\frac{1}{2}+(d-1) \alpha+$ $1+(1-2 d) \alpha / 2=(1-\alpha) / 2$ and is negative iff $\alpha>1$. This completes the proof of (3.63).

To prove (3.64), we use Corollary 3.1. We have

$$
\begin{align*}
& \sum_{\substack{t, k=n-1 \\
t \neq k}}^{\infty}\left|n^{-1 / \alpha} \kappa_{n}(k, t)\right|^{\mu} \\
& \quad=O\left(\int_{n}^{\infty}\left(\int_{k}^{\infty}\left|n^{-1 / \alpha} t^{d-1} k^{d-1} n^{1-2 d+\delta}\right|^{\mu} d t\right) d k\right)  \tag{3.72}\\
& \quad=O\left(n^{(1+\delta-1 / \alpha-2 d) \mu} \int_{n}^{\infty} k^{(d-1) \mu} \int_{n}^{\infty} t^{(d-1) \mu} d t d k\right) \\
& \quad=O\left(n^{(1+\delta-1 / \alpha-2 d) \mu+2(d-1) \mu+2}\right),
\end{align*}
$$

which again tends to 0 as $n \rightarrow \infty$ for $\mu$ sufficiently close to $\alpha$. This completes the proof of (3.64) and (3.54) with $u=2$.

Step 3. The proof of (3.54) with $u=3$ is the same as in the case $u=1$.
Step 4. The case $u=4$ is dealt with similarly to the previous three cases. Write

$$
\int_{-\pi}^{\pi}\left|\Gamma_{4 n}(\lambda)\right|^{2}|\eta(\lambda)| d \lambda=\nu_{n} \sum_{t=1}^{n} Z_{t}^{2}+\sum_{1 \leq t \neq k \leq n} \kappa_{n}(t, k) Z_{t} Z_{k},
$$

where now

$$
\nu_{n}=\int_{-\pi}^{\pi}\left|\sum_{j=n}^{\infty} c_{j} e^{-i \lambda j}\right|^{2}|\eta(\lambda)| d \lambda
$$

and

$$
\kappa_{n}(k, t)=\int_{-\pi}^{\pi}\left|\sum_{j=n}^{\infty} c_{j} e^{-i \lambda j}\right|^{2}|\eta(\lambda)| e^{i \lambda(k-t)} d \lambda .
$$

By Lemma 3.1 and (3.56) we obtain

$$
\nu_{n}=O\left(n^{d-1}\right) \quad \text { and } \quad \kappa_{n}(t, k)=O\left(n^{d-1}\right) .
$$

Consequently, Proposition 3.3 and the condition $d<1-1 / \alpha$ imply

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{t=1}^{n} \nu_{n} Z_{t}^{2} \leq K n^{(1 / \alpha)=d-1}\left(n^{-2 / \alpha} \sum_{t=1}^{n} Z_{t}^{2}\right) \rightarrow_{P} 0 . \tag{3.73}
\end{equation*}
$$

The relation

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{1 \leq t<k \leq n} \kappa_{n}(k, t) Z_{t} Z_{k} \rightarrow_{P} 0 \tag{3.74}
\end{equation*}
$$

follows, by Corollary 3.1, from the relation

$$
\sum_{1 \leq t<k \leq n}\left|n^{-1 / \alpha} n^{d-1}\right|^{\mu} \rightarrow 0,
$$

which is easily seen to hold for $\mu$ sufficiently close to $\alpha$.
This proves (3.54) with $u=4$, completing the proof of Lemma 3.4.

Proof of Lemma 3.5. Here it is convenient to split $\Delta_{n}(\lambda)$ as

$$
\Delta_{n}(\lambda)=\Delta_{1 n}(\lambda)+\Delta_{2 n}(\lambda)+\Delta_{3 n}(\lambda),
$$

where

$$
\begin{aligned}
& \Delta_{1 n}(\lambda)=\Gamma_{1 n}(\lambda)+\Gamma_{2 n}(\lambda)=\sum_{t=1}^{n-1} e^{-i \lambda t}\left(\sum_{j=t}^{\infty} c_{j} Z_{t-j}\right), \\
& \Delta_{2 n}(\lambda)=\Gamma_{3 n}(\lambda)=-e^{-i \lambda n} \sum_{t=1}^{n-1} e^{-i \lambda t}\left(\sum_{j=t}^{n-1} c_{j} Z_{n+t-j}\right), \\
& \Delta_{3 n}(\lambda)=\Gamma_{4 n}(\lambda)=-\left(\sum_{j=n}^{\infty} c_{j} e^{-i \lambda j}\right) \sum_{t=1}^{n} Z_{t} e^{-i \lambda t} .
\end{aligned}
$$

We verify below that

$$
\begin{equation*}
n^{-1 / \alpha} \int_{-\pi}^{\pi} \Delta_{u n}(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right) C(\lambda) \eta(\lambda) d \lambda \rightarrow_{P} 0 \tag{3.75}
\end{equation*}
$$

for $u=1,2,3$.
To prove (3.75) for $u=1$ and $u=2$, we need the following lemma.
Lemma 3.6. Suppose $C(\lambda)=\sum_{j=-\infty}^{\infty} c_{j} e^{i \lambda j}$ and $E(\lambda)=\sum_{k=-\infty}^{\infty} e_{k} e^{i \lambda k}$ are functions on $[-\pi, \pi]$ whose Fourier coefficients satisfy

$$
\begin{equation*}
c_{j}=O\left(|j|^{d-1}\right), \quad e_{k}=O\left(|k|^{-\varepsilon-1}\right) \tag{3.76}
\end{equation*}
$$

for some $0<d<1 / 2$ and $\varepsilon>0$. Then the Fourier coefficients of the product CE satisfy

$$
\begin{equation*}
h_{l}:=\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i \lambda l} C(\lambda) E(\lambda) d \lambda=O\left(l^{d-1}\right) . \tag{3.77}
\end{equation*}
$$

Proof. Conditions (3.76) imply that both $C$ and $E$ are in $L^{2}[-\pi, \pi]$, so $h_{l}=\sum_{j=-\infty}^{\infty} c_{j} e_{l-j}$. We have, for $l>0$,

$$
\left|h_{l}\right| \leq \sum_{|j| \leq l / 2}\left|c_{j}\right|\left|e_{l-j}\right|+\sum_{|j|>l / 2}\left|c_{j}\right|\left|e_{l-j}\right| .
$$

By (3.76),

$$
\begin{aligned}
\sum_{|j| \leq l / 2}\left|c_{j}\right| e_{l-j} \mid & =O\left(\sum_{|j| \leq l / 2}|j|^{d-1}|l-j|^{-\varepsilon-1}\right) \\
& =O\left(\int_{0}^{l / 2} j^{d-1}(l-j)^{-\varepsilon-1} d_{j}\right) \\
& =O\left(l^{d-1-\varepsilon} \int_{0}^{1 / 2} x^{d-1}(1-x)^{-\varepsilon-1} d x\right) \\
& =O\left(l^{d-1-\varepsilon}\right)=O\left(l^{d-1}\right)
\end{aligned}
$$

and

$$
\sum_{|j|>l / 2}\left|c_{j}\right|\left|e_{l-j}\right|=O\left(\sum_{|j|>l / 2}|j|^{d-1}\left|e_{l-j}\right|\right)=O\left(l^{d-1} \sum_{k=-\infty}^{\infty}\left|e_{k}\right|\right)=O\left(l^{d-1}\right) .
$$

Now introduce the function

$$
H(\lambda)=C(\lambda) \eta(\lambda)=\sum_{j=1}^{p+q+1} u_{j} C(\lambda) \frac{\partial}{\partial \beta_{j}} g^{-1}\left(\lambda, \beta_{0}\right) .
$$

By Lemma 5 on page 526 of Fox and Taqqu [12], the Fourier coefficients of the functions $\left(\partial / \partial \beta_{j}\right) g^{-1}\left(\lambda, \beta_{0}\right)$ are $O\left(|k|^{-2 d-1+\delta}\right)$, so applying Lemma 3.6 (with $E=\eta$ ) we see that $H(\lambda)=\sum_{l=-\infty}^{\infty} h_{l} e^{i \lambda l}$, where

$$
\begin{equation*}
h_{l}=O\left(|l|^{d-1}\right) . \tag{3.78}
\end{equation*}
$$

Using (3.78) and the elementary identity

$$
\begin{equation*}
\left(\sum_{t=1}^{n-1} a_{t} e^{-i \lambda t}\right)\left(\sum_{k=1}^{n} b_{k} e^{i \lambda k}\right)=\sum_{s=1}^{n-1} A_{s} e^{i \lambda s}+\sum_{s=0}^{n-2} A_{-s} e^{-i \lambda s}, \tag{3.79}
\end{equation*}
$$

where

$$
A_{s}=\sum_{t=1}^{n-s} a_{t} b_{t+s}, \quad s>0, \quad \text { and } \quad A_{-s}=\sum_{t=1}^{n-1-s} b_{t} a_{t+s}, \quad s \geq 0
$$

we shall now show that for $u=1$ and $u=2$,

$$
\begin{equation*}
n^{-1} \int_{-\pi}^{\pi} H(\lambda) \Delta_{u n}(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right) d \lambda \rightarrow_{P} O . \tag{3.80}
\end{equation*}
$$

Step 1. Consider first the case $u=1$. By (3.79), $\Delta_{1 n}(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right)=$ $\sum_{s=1}^{n-1} A_{s} e^{i \lambda s}+\sum_{s=0}^{n-2} A_{-s} e^{-i \lambda s}$, where

$$
A_{s}=\sum_{t=1}^{n-s}\left(\sum_{j=t}^{\infty} c_{j} Z_{t-j}\right) Z_{t+s} \quad \text { and } \quad A_{-s}=\sum_{t=1}^{n-1-s} Z_{t}\left(\sum_{j=t+s}^{\infty} c_{j} Z_{t+s-j}\right) .
$$

Consequently,

$$
\begin{aligned}
\frac{1}{2 \pi} & \int_{-\pi}^{\pi} H(\lambda) \Delta_{1 n}(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right) d \lambda \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi}\left(\sum_{l=-\infty}^{\infty} h_{l} e^{i \lambda l}\right)\left(\sum_{s=1}^{n-1} A_{s} e^{i \lambda s}+\sum_{s=0}^{n-2} A_{-s} e^{-i \lambda s}\right) d \lambda \\
& =\sum_{s=1}^{n-1} h_{-s} A_{s}+\sum_{s=0}^{n-2} h_{s} A_{-s} .
\end{aligned}
$$

We will show that

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{s=1}^{n-1} h_{-s} A_{s}=n^{-1 / \alpha} \sum_{s=1}^{n-1} h_{-s} \sum_{t=1}^{n-s}\left(\sum_{j=t}^{\infty} c_{j} Z_{t-j}\right) Z_{t+s} \rightarrow_{P} 0 \tag{3.81}
\end{equation*}
$$

the verification of

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{s=0}^{n-2} h_{s} A_{-s}=n^{-1 / \alpha} \sum_{s=0}^{n-2} h_{s} \sum_{t=1}^{n-1-s} Z_{t}\left(\sum_{j=t+s}^{\infty} c_{j} Z_{t+s-j}\right) \rightarrow_{P} 0 \tag{3.82}
\end{equation*}
$$

being similar.
By Corollary 3.1, since the bilinear form in (3.81) has no diagonal elements, it suffices to verify that for some $\mu<\alpha$,

$$
\begin{equation*}
n^{-\mu / \alpha} \sum_{s=1}^{n-1}\left|h_{-s}\right|^{\mu} \sum_{t=1}^{n-s} \sum_{j=t}^{\infty}\left|c_{j}\right|^{\mu} \rightarrow 0 . \tag{3.83}
\end{equation*}
$$

By (3.78), this reduces to showing

$$
\begin{equation*}
n^{-\mu / \alpha} \int_{1}^{n} s^{(d-1) \mu} d s \int_{1}^{n-s} d t \int_{t}^{\infty} j^{(d-1) \mu} d j \rightarrow 0 \tag{3.84}
\end{equation*}
$$

An elementary computation shows that the LHS of (3.84) is $O\left(n^{-\mu / \alpha+(d-1) \mu+2}\right)$. The condition $(d-1) \alpha+1<0$ guarantees that the exponent is negative for $\mu$ sufficiently close to $\alpha$.

Step 2. Now consider the case $u=2$. It is convenient to express $\Delta_{2 n}(\lambda)$ as $\Delta_{2 n}(\lambda)=-e^{-i \lambda n} \Delta_{2 n}^{\prime}(\lambda)$. By (3.79), $\Delta_{2 n}^{\prime}(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right)=\sum_{s=1}^{n-1} A_{s} e^{i \lambda s}+$ $\sum_{s=0}^{n-2} A_{-s} e^{-i \lambda s}$, where

$$
A_{s}=\sum_{t=1}^{n-s}\left(\sum_{j=t}^{n-1} c_{j} Z_{n+t-j}\right) Z_{t+s} \quad \text { and } \quad A_{-s}=\sum_{t=1}^{n-1-s} Z_{t}\left(\sum_{j=t+s}^{n-1} c_{j} Z_{n+t+s-j}\right) .
$$

Consequently,

$$
\begin{aligned}
-\frac{1}{2 \pi} & \int_{-\pi}^{\pi} H(\lambda) \Delta_{2 n}(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right) d \lambda \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{i \lambda n} H(\lambda) \Delta_{2 n}^{\prime}(\lambda)\left(\sum_{k=1}^{n} Z_{k} e^{i \lambda k}\right) d \lambda \\
& =\frac{1}{2 \pi} \int_{-\pi}^{\pi}\left(\sum_{j=-\infty}^{\infty} h_{j+n} e^{i \lambda j}\right)\left(\sum_{s=1}^{n-1} A_{s} e^{i \lambda s}+\sum_{s=0}^{n-2} A_{-s} e^{-i \lambda s}\right) d \lambda \\
& =\sum_{s=1}^{n-1} h_{n-s} A_{s}+\sum_{s=0}^{n-2} h_{n+s} A_{-s} .
\end{aligned}
$$

We first show that

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{s=1}^{n-1} h_{n-s} A_{s}=n^{-1 / \alpha} \sum_{s=1}^{n-1} h_{n-s} \sum_{t=1}^{n-s}\left(\sum_{j=t}^{n-1} c_{j} Z_{n+t-j}\right) Z_{t+s} \rightarrow_{P} 0 . \tag{3.85}
\end{equation*}
$$

The bilinear form in (3.85) contains diagonal elements, so we prove separately that

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{s=1}^{n-1} h_{n-s} \sum_{t=1}^{n-s} c_{n-s} Z_{t+s}^{2} \rightarrow_{P} 0 \tag{3.86}
\end{equation*}
$$

and

$$
\begin{equation*}
n^{-1 / \alpha} \sum_{s=1}^{n-1} h_{n-s} \sum_{t=1}^{n-1}\left(\sum_{\substack{j=t \\ j \neq n-s}}^{n-1} c_{j} Z_{n+t-j}\right) Z_{t+s} \rightarrow_{P} 0 \tag{3.87}
\end{equation*}
$$

To prove (3.86), observe that

$$
\begin{align*}
\sum_{s=1}^{n-1} h_{n-s} \sum_{t=1}^{n-s} c_{n-s} Z_{t+s}^{2} & =\sum_{j=1}^{n-1} h_{j} c_{j} \sum_{t=1}^{j} Z_{t+n-j}^{2} \\
& =\sum_{m=2}^{n} Z_{m}^{2}\left(\sum_{j=n-m+1}^{n-1} h_{j} c_{j}\right)  \tag{3.88}\\
& =\sum_{m=2}^{n} Z_{m}^{2}\left\{\frac{1}{2 \pi} \int_{-\pi}^{\pi} H(\lambda)\left(\sum_{j=n-m+1}^{n-1} c_{j} e^{-i \lambda j}\right)\right\} \\
& =\sum_{m=2}^{n} \nu_{n}(m) Z_{m}^{2} .
\end{align*}
$$

Since $H(\lambda)=C(\lambda) \eta(\lambda)=O\left(|\lambda|^{-d}|\lambda|^{2 d-\delta}\right)=O\left(|\lambda|^{d-\delta}\right)$ by (3.56), inequality (3.18) yields $\nu_{n}(m)=O\left((n-m+1)^{d-1}\right)$. Consequently, for any $\mu<\alpha$,

$$
\begin{align*}
E\left|n^{-1 / \alpha} \sum_{m=2}^{n} \nu_{n}(m) Z_{m}^{2}\right|^{\mu / 2} & \leq n^{-\mu / 2 \alpha} E\left|Z_{1}\right|^{\mu} \sum_{m=2}^{n}\left|\nu_{n}(m)\right|^{\mu / 2} \\
& \leq K n^{-\mu / 2 \alpha} \sum_{m=2}^{n}(n-m+1)^{(d-1) \mu / 2}  \tag{3.89}\\
& =K n^{-\mu / 2 \alpha} \sum_{l=1}^{n-1} l^{(d-1) \mu / 2} \\
& \leq K_{1} n^{-\mu / 2 \alpha+(d-1)(\mu / 2)+1} .
\end{align*}
$$

The condition $(d-1) \alpha+1<0$ again guarantees that the exponent in the last expression in (3.89) is negative, which proves (3.86).

To verify (3.87), it suffices to show

$$
\begin{equation*}
\left.n^{-\mu / \alpha} \sum_{s=1}^{n-1}\left|h_{n-s}\right|^{\mid}\right|^{n-s} \sum_{t=1}^{n-1} \sum_{j=t}^{n-1}\left|c_{j}\right|^{\mu} \rightarrow 0 . \tag{3.90}
\end{equation*}
$$

It is easy to check that the LHS of (3.90) is $O\left(n^{-\mu / \alpha+2(d-1) \mu+3}\right)$ and that the exponent is negative for $\mu<\alpha$ sufficiently close to $\alpha$.

We must also check that

$$
\begin{align*}
n^{-1 / \alpha} & \sum_{s=0}^{n-2} h_{n+s} A_{-s} \\
\quad= & n^{-1 / \alpha} \sum_{s=0}^{n-2} h_{n+s} \sum_{t=1}^{n-1-s} Z_{t}\left(\sum_{j=t+s}^{n-1} c_{j} Z_{n+t+s-j}\right) \rightarrow_{P} 0 . \tag{3.91}
\end{align*}
$$

Since the bilinear form in (3.91) has no diagonal elements, one checks as above that

$$
\begin{equation*}
n^{-\mu / \alpha} \sum_{s=0}^{n-2}\left|h_{n+s}\right|^{\mu} \sum_{t=1}^{n-1-s} \sum_{j=t+s}^{n-1}\left|c_{j}\right|^{\mu} \rightarrow 0 \tag{3.92}
\end{equation*}
$$

if $\mu<\alpha$ is sufficiently close to $\alpha$.
Step 3. It remains to verify (3.75) with $u=3$. Denote the left-hand side of (3.75) by $-n^{-1 / \alpha} I_{4 n}$. Then $I_{4 n}=I_{4 n 1}+2 I_{4 n 2}$, where $I_{4 n 1}=\nu_{n} \sum_{t=1}^{n} Z_{t}^{2}$ with $\nu_{n}=\int_{-\pi}^{\pi} C(\lambda)\left(\sum_{j=n}^{\infty} c_{j} e^{-i \lambda j}\right) \eta(\lambda) D \lambda$ and

$$
I_{4 n 2}=\sum_{k=1}^{n-1} \sum_{t=1}^{n-k} \kappa_{n}(k) Z_{t} Z_{t+k}
$$

with

$$
\kappa_{n}(k)=\int_{-\pi}^{\pi} C(\lambda)\left(\sum_{j=n}^{\infty} c_{j} e^{-i \lambda j}\right) \cos (\lambda k) \eta(\lambda) d \lambda .
$$

One can verify that $n^{-1 / \alpha} I_{4 n i} \rightarrow_{P} 0, i=1,2$, in the same way as relations (3.73) and (3.74). This completes the proof of Lemma 3.5.
4. Simulation. The estimator $\beta_{n}$ of the unknown parameter vector $\beta$ minimizes the function $\sigma_{n}^{2}(\beta)$ in (1.12). To find $\beta_{n}$, one can use, without modification, programs for Gaussian time series, for example, the one given in Section 12.1.3 of Beran [2]. These programs follow the minimization procedure described in Fox and Taqqu [12]. This procedure differs from the one discussed in Section 1 in two respects, neither of which affects the results. The division by $\sum_{i=1}^{n} X_{i}^{2}$ in (1.10) can be ignored because this quantity does not depend on the unknown parameter vector $\beta$. There is also no need for subtracting $\int_{-\pi}^{\pi} \log g(\lambda, \beta) d \lambda$ as in Fox and Taqqu [12], because, in the case of FARIMA, this integral equals a constant independent of $\beta$.

Mikosch, Gadrich, Klüppelberg and Adler [21] ran a simulation using ARMA sequences. Focusing on long-range dependence, we generate here FARIMA ( $0, d, 0$ ) sequences with $S \alpha S$ innovations. In the Gaussian case $\alpha=2$, one can apply the Durbin-Levinson algorithm (see Brockwell and Davis [5]) to generate an exact FARIMA, using for example, the arima.fracdiff.sim function in S-Plus. Because there is no known technique to generate an exact FARIMA in the stable case, we will approximate the infinite moving
average (1.4) by the finite one

$$
\begin{equation*}
X_{t}=\sum_{j=0}^{J} c_{j} Z_{t-j}, \quad t=1, \ldots, n \tag{4.1}
\end{equation*}
$$

Here $c_{j}=\Gamma(j+d) /(\Gamma(d) \Gamma(j+1)$ ) (see relation (7.13.1) in Samorodnitsky and Taqqu [24]) and, therefore, these coefficients can be easily obtained by using the recursion relation

$$
c_{0}=1, \quad c_{j+1}=\frac{j+d}{j+1} c_{j} .
$$

The $S \alpha S$ innovations are obtained through the S-Plus function rstab which uses a version of the Chambers, Mallow and Stuck [6] algorithm described in Section 1.7 of Samorodnitsky and Taqqu [24].

We set $J=1000$ in (4.1) and simulate series with parameters

$$
(\alpha, d)=(1.2,0.1),(1.5,0.2),(2,0.1),(2,0.2)
$$

and sample sizes $n=100,1000$ and 10,000 . Observe that $0<d<1-1 / \alpha$. We included the Gaussian $\alpha=2$, so that one can compare the results with this known case. Gaussian series are generated with the S-Plus function arima.fracdiff.sim referred to earlier.

For each kind of time series, we generated 50 independent samples and reported the average values of the estimates of $d$, the corresponding sample standard deviations and the square root of the sample MSEs. The following notation is used. If $d_{0}$ is the nominal value of $d$ and $d_{i}$ is the estimate for sample $i$, then

$$
\bar{d}=\frac{1}{50} \sum_{i=1}^{50} d_{i}, \quad \hat{\sigma}^{2}=\frac{1}{49} \sum_{i=1}^{50}\left(d_{i}-\bar{d}\right)^{2}, \quad \mathrm{MSE}=\frac{1}{50} \sum_{i=1}^{50}\left(d_{i}-d_{0}\right)^{2} .
$$

The results are summarized in Table 1. Figure 1 displays the corresponding box plots and shows the relative scatter of the 50 estimates. The vertical axis

Table 1
Estimation results for $d$ using 50 replications

|  |  |  |  |  |  |

| $\boldsymbol{n}$ |  | $\boldsymbol{\alpha}=\mathbf{1 . 2}$ <br> $\boldsymbol{d}=\mathbf{0 . 1}$ | $\boldsymbol{\alpha}=\mathbf{1 . 5}$ <br> $\boldsymbol{d}=\mathbf{0 . 2}$ | $\boldsymbol{\alpha}=\mathbf{2}$ <br> $\boldsymbol{d}=\mathbf{0 . 1}$ | $\boldsymbol{\alpha}=\mathbf{2}$ <br> $\boldsymbol{d}=\mathbf{0 . 2}$ |
| 100 | Average | 0.066 | 0.161 | 0.087 | 0.161 |
|  | $\hat{\sigma}$ | 0.079 | 0.059 | 0.089 | 0.095 |
|  | $\sqrt{\text { MSE }}$ | 0.085 | 0.071 | 0.089 | 0.102 |
| 1,000 | Average | 0.096 | 0.195 | 0.098 | 0.196 |
|  | $\hat{\sigma}$ | 0.021 | 0.030 | 0.027 | 0.026 |
|  | $\sqrt{\text { MSE }}$ | 0.021 | 0.030 | 0.027 | 0.026 |
|  | Average | 0.099 | 0.200 | 0.101 | 0.200 |
| 10,000 | $\hat{\sigma}$ | 0.005 | 0.006 | 0.008 | 0.007 |
|  | $\sqrt{\text { MSE }}$ | 0.005 | 0.006 | 0.008 | 0.007 |

Whittle Estimator applied to FARIMA(0,d,0)

Fig. 1.
in the figure indicates the deviations from the nominal values of $d$. For each time series we have (1) a thick line for the median; (2) a box representing the middle $50 \%$ of the data; (3) "whiskers" encompassing approximately $95 \%$ of the data, and designated by dashed lines; (4) outliers that fall beyond the whiskers

The parameter $d$, as is well known, is hard to estimate when the time series is short. As in the Gaussian case, $\hat{\sigma}$ and $\sqrt{\text { MSE }}$ are relatively large for $n=100$. The estimates improve dramatically for large sample sizes. They are very good when $n=1000$ and excellent when $n=10,000$.

Acknowledgments. The authors would like to thank Thomas Mikosch for pointing out an error in the original proof of Lemma 3.5, Vadim Teverovsky for performing the simulations and also the two anonymous referees.
