The Posterior metric and the Goodness of Gibbsianness for transforms of Gibbs measures

Christof Külske* and Alex A. Opoku†

Abstract

We present a general method to derive continuity estimates for conditional probabilities of general (possibly continuous) spin models subjected to local transformations. Such systems arise in the study of a stochastic time-evolution of Gibbs measures or as noisy observations. Assuming no a priori metric on the local state spaces but only a measurable structure, we define the posterior metric on the local image space. We show that it allows in a natural way to divide the local part of the continuity estimates from the spatial part (which is treated by Dobrushin uniqueness here).

We show in the concrete example of the time evolution of rotators on the $(q - 1)$ -dimensional sphere how this method can be used to obtain estimates in terms of the familiar Euclidean metric. In another application we prove the preservation of Gibbsianness for sufficiently fine local coarse-grainings when the Hamiltonian satisfies a Lipschitz property .

Key words: Time-evolved Gibbs measures, non-Gibbsian measures, Dobrushin uniqueness, phase transitions, specification, posterior metric.

1 Introduction

The absence or presence of phase transitions lies at the heart of mathematical statistical mechanics of equilibrium systems. A phase transition in an order parameter that can be directly observed is of an obvious interest for the system under investigation. Moreover sometimes also the presence or absence of phase transitions is linked in a more subtle way to the properties of the system under investigation. In fact, it is understood that "hidden phase transitions" in an internal system that is not directly observable are responsible for the failure of the Gibbs property for a variety of important measures that appear as transforms of various Gibbs measures. For the mechanisms of how to become non-Gibbs and background on renormalization group type of pathologies and beyond, see the reviews [11; 8; 5].

The first part of the analysis of an interacting system begins with an understanding of the "weak coupling regime" and proving results based on absence of phase transitions when the system variables behave as a perturbation of independent ones. There is a variety of competing ways at our disposition to do so, giving related but usually not equivalent results, notably Dobrushin's uniqueness theory [14; 1], expansion methods, and percolation and coupling methods.

When it works, Dobrushin uniqueness has a lot of advantages, being not very technical, but very general, requiring little explicit knowledge of the system and providing explicit estimates on decay of correlations. Moreover, it implies useful properties generalizing those of independent variables. As an example of such a useful property we mention Gaussian concentration estimates of functions of the system variables which are obtained as a corollary when there is an estimate on the Dobrushin interaction matrix available [6; 7]. Especially when we are talking about continuous spin systems a Dobrushin uniqueness approach seems favorable, since cluster expansions are often applicable only with some technical effort [19; 12], and percolation and coupling are not directly available.

A particular interest has been in recent times in the study of the loss and recovery of the Gibbs property of an initial Gibbs measure under a stochastic time-evolution. The study started in [4] where the authors focused on the evolution of a Gibbs measure of an Ising model under high-temperature spin-flip Glauber dynamics. The main phenomenon observed therein was the loss of the Gibbs property after a certain transition time when the system was started at an initial low temperature state. The measure stays non-Gibbs forever when the initial external field was zero. More complicated transition phenomena between Gibbs and non-Gibbs are possible at intermediate times when there is no spin-flip symmetry: The Gibbs property is recovered again at large but finite values of time in the presence of non-vanishing external magnetic fields in the external measure. A complete analysis of the corresponding Ising mean-field system in zero magnetic field was given in [3] where the authors analyzed the time-temperature dynamic phase diagram describing the Gibbs non-Gibbs transitions. In the analysis also the phenomenon of symmetry breaking in the set of bad configurations was detected, meaning that a bad configuration whose spatial average does not preserve the spin-flip symmetry of the model appears.

What remains of these phenomena for continuous spins? The case of site-wise independent diffusions of continuous spins on the lattice starting from the Gibbs-measure of a special double-well potential was considered in [10]. It was shown therein that a similar loss of Gibbsianness will occur if the initial double-well potential is deep enough. In contrast to the Ising model, this loss however is a loss without recovery, so the measure stays non-Gibbs for all sufficiently large times. This is due to the unbounded nature of the spins. Short-time Gibbsianness is proved

to hold also in this model. While these results hold for a continuous spin model, the method of proof is nevertheless based on the investigation of a "hidden discrete model", exploiting the particular form of the Gibbs-potential. In [17] the authors studied models for compact spins, namely the planar rotator models on the circle subjected to diffusive time-evolution. It is shown therein that starting with an initial low-temperature Gibbs measure, the time-evolved measure obtained for infinite- or high-temperature dynamics stays Gibbs for short times and for the corresponding initial infinite- or high- temperature Gibbs measure under infinite- or high-temperature dynamics, the time-evolved measure stays Gibbs forever. Their analysis uses the machinery of cluster expansions, as earlier developed in [22]. Even before it was shown that the whole process of space-time histories can be viewed as a Gibbs measure [21]. This is interesting in itself, but does not imply that fixed-time projections are Gibbs.

Short-time Gibbsianness in all these models follows from uniqueness of a hidden or internal system. While this is expected to hold very generally, results that are not restricted to particular models appear only for discrete spin systems [9]. The present paper now narrows the gap. It provides a proof of the preservation of the Gibbs property of the time-evolved Gibbs-measures of a general continuous spin system under site-wise independent dynamics, for short times, even when the initial measure is in the strong coupling regime. Intuitively speaking strong couplings offer the possibility for a phase transition not only in the initial system but also in the internal system, which will however be suppressed for small times, but usually only for small times. Small couplings offer no possibility for a phase and it is much easier to show the preservation of Gibbsianness for all times.

More generally than for time-evolution, we prove our results directly for general two layer systems, consisting of (1) a Gibbs measure in the first layer, that is (2) subjected to local transition kernels mapping the first-layer variables to second-layer variables. This generalizes the notion of a hidden Markov model where the second layer plays the role of a noisy observation. Such models have motivations in a variety of fields. Let us mention for example that they appear in biology as models of gene regulatory networks where the vertices of the network are genes and the variables model gene expression activities.

A measure is Gibbsian when the single-site conditional probabilities depend on the conditioning in an essentially local way. Our main statement (Theorem 2.5) is an explicit upper bound on the continuity of the single-site conditional probabilities of the second-layer system as a function of the conditioning. This is valid when the transition kernels don't fluctuate too much, even when the first-layer system is in a strong coupling regime. Our result holds for discrete or continuous compact state spaces and general interactions and is based on Dobrushin uniqueness. To formulate the resulting continuity estimate for the conditional probabilities we don't need any a priori metric structure on the local-spin spaces: The natural metric on the second-layer-single-spin space is created by the variational distance between the a-priori measures in the first layer that are obtained by conditioning on second layer configurations (see Theorem 2.5).

On the way to this result, we exhibit a simple criterion for Dobrushin uniqueness for Gibbs-measures (of one layer). It is easy to check and can be of use beyond the study of (non)-Gibbsianness.

Intuitively, it demands that the sum over the interaction terms in the Hamiltonian coupling the sites i and j should not fluctuate too much when it is viewed as a random variable at the site i under the corresponding local a priori measure (see Definition 2.2). So even when one has a large interaction, better concentration properties of the a priori measures can still imply

an overall small Dobrushin constant. This is a generalization of the simple large-field criterion ensuring Dobrushin-uniqueness in the Ising model (see p.147 example 8.13 of [1] and [20]) to general spaces (Theorem 2.3).

The criterion we need for the study of the second-layer model is based on the description of the interplay between the possible largeness of the initial interaction and the strength of the coupling to the second layer found in Theorem 2.3 (when the initial a priori measures are replaced with conditional a priori measures). To ensure Gibbsianness of the second-layer model, we thus need small fluctuations of the initial Hamiltonian w.r.t. the a-priori measures in the first layer that are obtained by conditioning on second-layer configurations. The estimates on the spatial memory of the second-layer-single-site conditional probabilities follow naturally by evoking Dobrushin-uniqueness estimates on comparison of the Gibbs measures with perturbed specifications and chain-rule type of arguments.

To illustrate the simplicity of our approach to get explicit estimates on the spatial decay we prove short-time Gibbsianness of a model of $(q - 1)$ -dimensional rotators for general $q \geq 2$ under diffusive time-evolution on the $(q - 1)$ -spheres, and provide an explicit estimate on the time-interval for which the time-evolved measure stays Gibbs. This will be supplemented by arguments that are more specific to the rotators which give us precise continuity estimates in terms of the Euclidean distances on the spheres. As another application of our approach we show Gibbsianness of initial system (with Lipschitz continuous Hamiltonian) subjected to local coarse-grainings. Here the transformed system will be Gibbs if the local coarse-graining is fine enough.

The rest of the paper is organized as follows: In Section 2 we formulate our main results. From Sections 3 to 5 we present the proofs of the main results and state some further results that are also of interest in themselves.

2 Main Results

2.1 Preliminaries and definitions

Before we formulate our results we recall some generalities on Gibbs measures for spin systems ([1; 11; 14]). Let G be a countable vertex set (for example $G = \mathbb{Z}^d$, $d \geq 1$) and denote by \mathcal{S} the set of finite subsets of G . We write $\Lambda^c := G \setminus \Lambda$ for any subset Λ of G and whenever $\Lambda = \{i\}$, we shall in the sequel write i^c instead of Λ^c . We denote by $\sigma = (\sigma_i)_{i \in G}$ the spin-variables where the σ_i 's are taking values in a standard Borel space S (i.e. a measurable space with a metric which turns it into a complete separable metric space equipped with the Borel σ -algebra generated by the metric) equipped an a-priori Borel probability measure α (single-spin space). In our general set-up we don't need to make a metric structure on S explicit. We further denote by $\Omega := S^G$ the configuration space of our system equipped with the product Borel σ -algebra \mathcal{F} . We write \mathcal{F}_Λ for the sub- σ -algebra generated by the σ_i 's for $i \in \Lambda \subset G$. A real-valued function defined on the configuration space is said to be *local* if it is measurable w.r.t. \mathcal{F}_Λ for some finite subset $\Lambda \subset G$ and is said to be *quasilocal* if it is a uniform limit of local functions.

A *specification* on (Ω, \mathcal{F}) is a family $\gamma = \{\gamma_\Lambda, \Lambda \in \mathcal{S}\}$ of probability kernels from Ω_{Λ^c} to \mathcal{F} which are *proper* and *consistent*. Properness means that $\gamma_\Lambda(B|\omega) = 1_B(\omega)$ whenever B is measurable

w.r.t. \mathcal{F}_{Λ^c} . Consistency means that $\gamma_{\Lambda'}\gamma_{\Lambda} = \gamma_{\Lambda'}$ whenever $\Lambda \subset \Lambda'$. Here the notation on the l.h.s. indicates the composition of probability kernels.

A specification is said to be *quasilocal* if its application to any quasilocal function f on Ω , denoted by $\gamma_{\Lambda}(f)$, is again a quasilocal function. A specification is said to be *uniformly nonnull* if, for each $\Lambda \in \mathcal{S}$ there exist constants $0 < u_{\Lambda} \leq v_{\Lambda} < \infty$ such that $u_{\Lambda}\alpha^{\Lambda}(A) \leq \gamma_{\Lambda}(A|\omega) \leq v_{\Lambda}\alpha^{\Lambda}(A)$, for all $\omega \in \Omega$ and $A \in \mathcal{F}_{\Lambda}$. Here α^{Λ} is the free specification obtained by putting a fixed boundary condition outside Λ and integrating over the product measure inside Λ , that is $\alpha_{\Lambda}(f|\omega) = \int \prod_{i \in \Lambda} \alpha(d\sigma_i) f(\sigma_{\Lambda}\omega_{\Lambda^c})$. A specification is called *Gibbsian* if it is quasilocal and uniformly nonnull.

Given a Gibbsian specification γ we say that a probability measure μ on Ω is a *Gibbs measure* for γ whenever, for each $\Lambda \in \mathcal{S}$,

$$\mu\gamma_{\Lambda} = \mu. \tag{1}$$

The above equation is called the DLR-equation. We denote by $\mathcal{G}(\gamma)$ the set of Gibbs measures for γ .

Often a specification will not just be abstractly defined, but given in terms of an *interaction*, or a Hamiltonian. The interaction among the components of the systems we shall consider is a family $\Phi = (\Phi_A)_{A \in \mathcal{S}}$ of local functions Φ_A (called interaction potential) satisfying the following summability condition:

$$\|\Phi\| := \sup_{i \in G} \sum_{A \in \mathcal{S}: A \ni i} |A| \|\Phi_A\|_{\infty} < \infty. \tag{2}$$

(2) implies the most frequently found condition of absolute summability, i.e

$$\sup_{i \in G} \sum_{A \in \mathcal{S}: A \ni i} \|\Phi_A\|_{\infty} < \infty. \tag{3}$$

Given an interaction Φ and a fixed configuration $\omega \in \Omega$, we introduce for each $\Lambda \in \mathcal{S}$

$$H_{\Lambda}(\sigma_{\Lambda}\omega_{\Lambda^c}) := \sum_{A: A \cap \Lambda \neq \emptyset} \Phi_A(\sigma_{\Lambda}\omega_{\Lambda^c}) \tag{4}$$

as the finite-volume Hamiltonian with ω as boundary condition. For a given absolutely summable interaction Φ we denote by $\gamma \equiv \gamma^{\beta\Phi}$ the Gibbsian specification (see [1]) given by

$$\gamma_{\Lambda}(d\sigma_{\Lambda}|\bar{\sigma}) := \exp(-\beta H_{\Lambda}(\sigma_{\Lambda}\bar{\sigma}_{\Lambda^c})) \prod_{i \in \Lambda} \alpha(d\sigma_i) / Z_{\Lambda}(\bar{\sigma}) \tag{5}$$

where $Z_{\Lambda}(\bar{\sigma})$ is the normalization constant and β is the inverse temperature. In the present paper β will always be absorbed into the interaction.

While it is important to know that a specification is quasilocal, we are aiming in this paper at statements refining the quasilocality, which describe the dependence of the single-site conditional probabilities γ_i on variations of the conditioning in more detail. To quantify the continuity of a specification we employ the following notion.

Definition 2.1. Assume that d is a metric on the single-spin space S , and assume that $Q = (Q_{i,j})_{i,j \in G}$ is a non-negative matrix with $\sup_{i \in G} \sum_{j \in G} Q_{i,j} = \|Q\|_\infty < \infty$.

A specification γ is called a Gibbsian specification of goodness (Q, d) if it is quasilocal, uniformly non-null, and the single-site kernels satisfy the continuity estimates

$$\left\| \gamma_i(d\eta_i | \eta_i^c) - \gamma_i(d\eta_i | \bar{\eta}_i^c) \right\| \leq \sum_{j \in G \setminus i} Q_{i,j} d(\eta_j, \bar{\eta}_j). \quad (6)$$

Here

$$\|\nu_1 - \nu_2\| := \sup_{f: |f| \leq 1} |\nu_1(f) - \nu_2(f)| = \frac{1}{2} \lambda(|h_1 - h_2|), \quad (7)$$

whenever ν_1 and ν_2 are probability measures that are absolutely continuous with respect to the measure λ with λ -densities h_1 and h_2 respectively (i.e. $\|\nu_1 - \nu_2\|$ is one half of the variational distance between ν_1 and ν_2) and the supremum is over observables on Ω .

The faster the decay of Q is, the faster the decay of conditional probabilities on variations of the conditioning is, and the "better" or the "more Gibbsian" the system of conditional probabilities is. We are restricting our attention to single-site γ_i 's since all γ_Λ for finite Λ can be expressed by an explicit formula in terms of the γ_i 's with $i \in \Lambda$. For the solution of this "reconstruction-problem" see [1; 23].

In particular we denote by $C = (C_{ij})_{i,j \in G}$ the Dobrushin interdependence matrix [1; 14], with entries given by

$$C_{ij} = \sup_{\zeta, \eta \in \Omega: \zeta_j^c = \eta_j^c} \|\gamma_i(\cdot | \zeta) - \gamma_i(\cdot | \eta)\|. \quad (8)$$

This means that C is the matrix with smallest matrix-elements for which the specification γ is of the goodness (C, d) , where d is the discrete metric on S given by $d(\eta_j, \eta'_j) = 1_{\eta_j \neq \eta'_j}$. The corresponding Dobrushin constant is given as

$$c := \sup_{i \in G} \sum_{j \in G} C_{ij}.$$

We recall that whenever $c < 1$ (Dobrushin uniqueness condition) and γ is quasilocal then γ admits at most one Gibbs measure [14; 1]. However if the single-spin space S is standard Borel (as in our case) then the above condition implies that γ admits a unique Gibbs measure (see Theorem 8.7, [1]). It is known that for a potential Φ satisfying (2) there is a sufficiently small β such that $\beta\Phi$ satisfies Dobrushin uniqueness and the measure is in a weak coupling regime, where the measure is a small perturbation of a product measure.

2.2 A bound on the Dobrushin constant for concentrated a priori measures

For our purposes we employ the following definition.

Definition 2.2. For a function $F : \Omega \mapsto \mathbb{R}$ we define the $\alpha; i, j$ -linear deviation $\text{dev}_{\alpha; i, j}$ of F to be

$$\text{dev}_{\alpha; i, j}(F) := \sup_{\substack{\zeta, \eta \in S^G \\ \zeta_{jc} = \eta_{jc}}} \inf_{b \in \mathbb{R}} \int \alpha(d\sigma_i) \left| F(\sigma_i \eta_{ic}) - F(\sigma_i \zeta_{ic}) - b \right|. \quad (9)$$

This quantity is the worst-case linear deviation of the variation of F at the site j viewed as a random variable w.r.t. to σ_i under $\alpha(d\sigma_i)$. Note that the linear deviation is bounded by $\delta_j(F)$, the j th oscillation of F , which is bounded by the oscillation of F , i.e.

$$\begin{aligned} \text{dev}_{\alpha; i, j}(F) &\leq \delta_j(F) = \sup_{\substack{\zeta, \eta \in \Omega \\ \zeta_{jc} = \eta_{jc}}} \left| F(\eta) - F(\zeta) \right| \\ &\leq \delta(F) = \sup_{\zeta, \eta \in \Omega} \left| F(\eta) - F(\zeta) \right|. \end{aligned} \quad (10)$$

Then our first result is as follows.

Theorem 2.3. The Dobrushin constant c is bounded by

$$c \leq \sup_{i \in G} \sum_{j \in G} \exp\left(\delta_j(H_i)\right) \text{dev}_{\alpha; i, j}(H_i). \quad (11)$$

The use of this bound lies in the fact that, even when the interaction potential is large, $\text{dev}_{\alpha; i, j}(H_i)$ can be small, when α is close to a Dirac measure. A simple example for this to happen is an Ising model at large external field, as it was discussed in [1]. Our bound produces the bound given there, but extends to general potentials. As a less trivial application of the our bound to a spin model where S is not discrete we discuss the Gauss-Weierstrass kernel in the rotator example of Section 2.4 where we use it to prove short-time Gibbsianness (see (23)).

Of course, when the potential is small to begin with, the r.h.s. of (11) will be small, independently of α , so the theorem can be used for both strong couplings and concentrated a priori measures, and weak coupling.

2.3 Two-layer models - Goodness of Gibbsianness

Let us now formulate our assumptions on a two-layer system over a graph G . To each vertex will be associated two local state spaces. A particular example will be given by the site-wise independent time-evolution of Section 2.4. So, in general let S and additionally S' be measurable (standard Borel) spaces. This implies in particular existence of all regular conditional probabilities. Again, no a priori metric will be used explicitly. We refer to S as the initial (first-layer) spin space and to S' as the image (second-layer) spin space. Let us take $K(d\sigma_i, d\eta_i)$ (Borel probability measure on the product space $S \times S'$) be the joint a-priori measure for the two-layer model. We assume that K can be written in the form $K(d\sigma_i, d\eta_i) = k(\sigma_i, \eta_i) \alpha(d\sigma_i) \alpha'(d\eta_i)$, where $\alpha(d\sigma_i) \equiv \int_{S'} K(d\sigma_i, d\eta_i)$, $\alpha'(d\eta_i) \equiv \int_S K(d\sigma_i, d\eta_i)$ and $\|\log k\|_\infty < \infty$.

Our initial model (probability measure on Ω) is by definition a Gibbs distribution for the specification given in terms of the potential Φ according to (5) where we now put as an a-priori

measure the marginal of K on the first layer, that is $\alpha(d\sigma_i) \equiv \int_{S'} K(d\sigma_i, d\eta_i)$. It is important to note that we don't assume uniqueness of the Gibbs measure for this specification. In practice α might be given beforehand and K is then obtained by specifying a transition kernel $K(d\eta_i|\sigma_i)$ from the first layer to the second layer. In the rest of this work we will (unless otherwise stated) denote by $\sigma_i \in S$ the local variable (spin) for the initial model and $\eta_i \in S'$ the local variable (spin) for the image model.

Let $\mu(d\sigma)$ be a Gibbs measure for the first layer for the potential Φ and a priori measure α . Our aim is then: Study the conditional probabilities of the second-layer measure defined by

$$\mu'(d\eta) := \int_{\Omega} \mu(d\sigma) \prod_{i \in G} K(d\eta_i|\sigma_i).$$

This form appears for instance in the study of a stochastic time evolution, starting from an initial measure μ where the kernel $K(d\eta_i|\sigma_i)$ will be dependent on time and is applied independently over the spins (infinite-temperature dynamics). In case studies it has been observed that the map $\mu \mapsto \mu'$ may create an image measure that is not a Gibbs measure anymore. On the other hand, in all examples observed, Gibbsianness was preserved at short times where $K(d\eta_i|\sigma_i)$ is a small perturbation of $\delta_{\sigma_i}(d\eta_i)$. We aim here to give a criterion that implies this in all generality, not using any specifics of the model but only the relevant underlying structure. In particular we are not restricting ourselves to discrete spin spaces.

Our main result Theorem 2.5 is a criterion for the Gibbs property of the second-layer measure to hold, that is easily formulated and verified in concrete examples. Moreover, we give explicit bounds on the dependence of the conditional probabilities of the second-layer measure on the variation of the conditioning, in the sense of Definition 2.1.

We said that we will not use any a priori metric on the spaces S and S' ; indeed the natural metric that shall be used for continuity in this set-up shall be given by the variational distance of the conditional a priori measures in the first layer, conditional on the second layer.

Set for each $i \in G$

$$\alpha_{\eta_i}(d\sigma_i) := K(d\sigma_i|\eta_i), \tag{12}$$

the a priori measures in the first layer that are obtained by conditioning on second layer configurations.

Definition 2.4. *We call*

$$d'(\eta_i, \eta'_i) := \|\alpha_{\eta_i} - \alpha_{\eta'_i}\| \tag{13}$$

the posterior (pseudo-)metric, associated to K on the second layer space.

d' satisfies non-negativity and triangular inequality, but we may have $d'(\eta_i, \eta'_i) = 0$ for $\eta_i \neq \eta'_i$ (which happens e.g. if σ_i and η_i are independent under K).

In the language of statistics, α_{η_i} is the "posterior measure" depending on the observation η_i in the second-layer-single-spin space. Stated abstractly, the metric d' is the pull back-metric of the map $\eta_i \mapsto \alpha_{\eta_i}(d\sigma_i)$ from single-site configurations in the second layer to single-site measures in the first layer. While this metric seems to be non-explicit, we will show in the rotator example how it can be estimated in terms of a more familiar metric (Euclidean metric).

It is a well-known heuristics which has been made precise in special cases that an investigation of the Gibbs property of the second layer measure must be based on an analysis of the first layer conditioned on configurations in the second layer [4; 5; 8; 12]. So, our estimates will naturally contain quantities that reflect this aspect. Let us put

$$\bar{B}_{ij} := \sup_{\eta_i} \text{dev}_{\alpha_{\eta_i}; i, j}(H_i), \quad \bar{C}_{ij} := \exp\left(\sum_{A \supset \{i, j\}} \delta(\Phi_A)\right) \bar{B}_{ij}. \quad (14)$$

We note that \bar{B}_{ij} is a uniform bound on the deviations of the initial Hamiltonian taken with a priori measures conditioned on the image configurations. The entries \bar{C}_{ij} are upper bounds on the conditional Dobrushin matrix for the corresponding constrained first-layer model. We warn the reader not to confuse $\text{dev}_{\alpha_{\eta_i}; i, j}(H_i)$ with $\text{dev}_{\alpha; i, j}(H_i)$. While the second quantity may be big and correspondingly the unconstrained first layer system in a non-uniqueness regime, the first one might still be small and correspondingly the constrained layer system in a uniqueness regime. This is e.g. the case for a time-evolution started at low temperature, for small times. Then we have the following theorem.

Theorem 2.5. *Suppose that the first-layer system has an infinite-volume Gibbs measure $\mu = \lim_n \mu_{\Lambda_n}^{\bar{\sigma}}$ obtained for a boundary condition $\bar{\sigma}$ and along a suitable sequence of volumes Λ_n .*

Suppose further that $\sup_i \sum_j \bar{C}_{ij} < 1$.

Then the family γ' of finite-volume conditional distributions of the transformed system is a Gibbsian specification of goodness (Q, d') where

$$Q_{ij} = 4e^{2 \sum_{A \ni i} \|\Phi_A\|_\infty} \left(\sum_{k \in G \setminus i} \delta_k \left(\sum_{A \supset \{i, k\}} \Phi_A \right) \bar{D}_{kj} \right) e^{\sum_{A \ni j} \delta_j(\Phi_A)} \quad (15)$$

with $\bar{D} = \sum_{n=0}^{\infty} \bar{C}^n$.

Remark: A formula for γ' is given below the statement of Proposition 4.7 in (63).

Note that the first layer system may be very well in a phase transition regime. For arbitrarily large interaction Φ , good concentration of the conditional measures α_{η_i} can still lead to a small \bar{B}_{ij} , which makes the \bar{C}_{ij} sufficiently small for the theorem to hold. In short: Uniform conditional Dobrushin uniqueness of the first layer implies Gibbsianness of the second layer, with explicit estimates.

The matrix Q describing the spatial loss of memory of the variation of the conditioning, depends on the decay properties of the Φ_A 's and of the \bar{D}_{kj} 's. E.g. in the case of a finite range potential, \bar{D}_{kj} dominates the decay of Q_{ij} . If we have $\sup_i \sum_j \bar{C}_{ij} e^{\lambda s(i, j)} < \infty$ where $s(i, j)$ is an arbitrary distance on G , (15) provides us with an exponential decay estimate of the form $Q_{ij} \leq C e^{-\lambda' s(i, j)}$ for some constant C .

Note that the summability property we impose on the initial potential (2) implies the finiteness of (15). In particular we have the following bound on the entries of the Q -matrix

$$Q_{ij} \leq 4 \exp\left(4 \sup_{i \in G} \sum_{A \ni i} \|\Phi_A\|_\infty\right) (M\bar{D})_{ij}, \quad (16)$$

where M is the matrix given by $M_{ik} = \begin{cases} \delta_k \left(\sum_{A \supset \{i, k\}} \Phi_A \right) & \text{if } i \neq k; \\ 0 & \text{if } i = k. \end{cases}$

All these quantities are easily made explicit in examples.

2.4 Short-time Gibbsianness for time-evolved rotator models

We begin this subsection more generally with an introduction of the following useful property we will impose on the initial interaction. For this purpose we now assume additionally a metric structure.

Definition 2.6. *Let (S, d) be a metric space. Denote by $L_{ij} = L_{ij}(\Phi)$ the smallest constants such that the j -variation of the Hamiltonian H_i satisfies*

$$\sup_{\substack{\zeta, \bar{\zeta} \\ \zeta_{jc} = \bar{\zeta}_{jc}}} \left| H_i(\sigma_i \zeta_{ic}) - H_i(\sigma_i \bar{\zeta}_{ic}) - \left(H_i(a_i \zeta_{ic}) - H_i(a_i \bar{\zeta}_{ic}) \right) \right| \leq L_{ij} d(\sigma_i, a_i). \quad (17)$$

We say that Φ satisfies a Lipschitz property with constants $(L_{ij}(\Phi))_{i,j \in G \times G}$, if all of these constants are finite.

Consider now the rotator model on G (a general graph with countable vertex set), with both first-layer and second-layer local spin spaces equal to S^{q-1} , the sphere in q -dimensional Euclidean space, with $q \geq 2$.

Take as (formal) Hamiltonian of the first-layer system in infinite-volume

$$H(\sigma) = - \sum_{i,j \in G} J_{ij} \sigma_i \cdot \sigma_j \quad \text{with} \quad \sup_i \sum_j |J_{ij}| < \infty, \quad (18)$$

where we assume that $J_{ii} = 0$ for each $i \in G$. In the above we have used “ \cdot ” to denote scalar product. Our model satisfies a Lipschitz property with constants $L_{ij}(\Phi) = 2|J_{ij}|$. For $G = \mathbb{Z}^d$ and $d \geq 3$ such a model has been proved to exhibit long-range order under suitable assumptions on the Fourier-transform of J (see [25]).

Let K be given by

$$K(d\sigma_i, d\eta_i) = K_t(d\sigma_i, d\eta_i) = k_t(\sigma_i, \eta_i) \alpha_o(d\sigma_i) \alpha_o(d\eta_i), \quad (19)$$

where α_o is the equidistribution on S^{q-1} and k_t is the heat kernel on the sphere, i.e.

$$\left(e^{\Delta t} \varphi \right) (\eta_i) = \int \alpha_o(d\sigma_i) k_t(\sigma_i, \eta_i) \varphi(\sigma_i), \quad (20)$$

where Δ is the Laplace-Beltrami operator (see e.g. p. 38, eq 54 of [2]) on the sphere and φ is any test function. k_t is also called the *Gauss-Weierstrass kernel*. For more background on the heat-kernel on Riemannian manifolds, see the introduction of [24].

The time-evolved measure is given by

$$\mu_t(d\eta) = \int \mu(d\sigma) \prod_i k_t(\sigma_i, \eta_i) \alpha_o(d\eta_i). \quad (21)$$

It has the product over the equidistributions on the spheres as an infinite-time local limiting measure

$$\lim_{t \uparrow \infty} \mu_t(d\eta) = \bigotimes_{i \in G} \alpha_o(d\eta_i). \quad (22)$$

Convergence takes place exponentially fast on local observables, the decay rate given by the first eigenvalue of the Laplacian on the sphere (see also (115)).

Theorem 2.7. Denote by $d(\eta, \eta')$ the induced metric on the sphere S^{q-1} (with $q \geq 2$) obtained by embedding the sphere into the Euclidean space \mathbb{R}^q .

Assume that

$$\sqrt{2} \left(\sup_i \sum_{j \in G} e^{|J_{ij}| |J_{ij}|} \right) \left(1 - e^{-(q-1)t} \right)^{\frac{1}{2}} < 1. \quad (23)$$

Then μ_t is a Gibbs measure for some Gibbsian specification γ'_t of goodness $(\bar{Q}(t), d)$ where

$$\bar{Q}_{ij}(t) := \frac{1}{2} \min \left\{ \sqrt{\frac{\pi}{t}} Q_{ij}(t), e^{4 \sum_l |J_{jl}|} - 1 \right\} \quad (24)$$

where

$$Q_{ij}(t) = 8e^{4 \sup_{i \in G} \sum_{j \in G} |J_{ij}|} \sum_{k \in G \setminus i} |J_{ik}| \bar{D}_{kj}(t), \quad (25)$$

$\bar{D}(t) = \mathbf{1} + \sum_{n=1}^{\infty} (1 - e^{-(q-1)t})^{\frac{n}{2}} A^n$, A is the matrix whose entries are given by $A_{ij} = e^{|J_{ij}| |J_{ij}|}$ and $\mathbf{1}$ is the identity matrix.

For the definition of $Q_{ij}(t)$ in (25) we have used the bound (16).

The proof of the theorem follows from three ingredients: 1) Theorem 2.5 which gives a continuity estimate in terms of the posterior metric d' , 2) a comparison result between d' and d , and 3) a telescoping argument over sites in the conditioning. Here is the comparison result.

Proposition 2.8. There is an estimate of the posterior metric d' associated to the measure K_t of the form

$$d'(\eta_j, \bar{\eta}_j) \leq \frac{\sqrt{\pi}}{2\sqrt{t}} d(\eta_j, \bar{\eta}_j). \quad (26)$$

Remark: The proof of the proposition uses a coupling argument and a reflection principle for diffusions on the sphere under reflection at the equator. A refinement of the estimates on d' in terms of an expansion of Legendre polynomials is found in Proposition 5.3 in the Appendix.

Let us come back to the discussion of Theorem 2.7 and explain the form of the bounds giving an idea of the proof. It is straightforward to apply Theorem 2.5 to our model and obtain a result formulated in d' . However, a more natural metric we would prefer to use is d , and so we should use Proposition 2.8. What continuity estimates do we expect to gain from this? It is not difficult to see by telescoping and using the standard interpolation trick also employed in the proof of Theorem 2.3 that for the initial kernel

$$\left\| \gamma_{t=0}(d\eta_i | \eta_{i^c}) - \gamma_{t=0}(d\eta_i | \bar{\eta}_{i^c}) \right\| \leq \sum_{j \in G} e^{2 \sum_{j \in G} |J_{ij}|} |J_{ij}| d(\eta_j, \bar{\eta}_j) \quad (27)$$

We see that continuity can be measured in terms of d , due to the Lipschitz property of the initial Hamiltonian, and the spatial decay is provided by the decay of the couplings.

So, at small time t , we are aiming at a similar continuity estimate to hold which is uniform in t as t goes to zero. Now, while estimating d' against d we have accumulated a nasty factor $\frac{1}{\sqrt{t}}$ that

blows up when time t goes to zero. We note that this is not just an artifact of Proposition 2.8, but the posterior metric between two points on the sphere indeed blows up like $\frac{1}{\sqrt{t}}$, as can be seen from the proof. At first sight this does not seem to be a problem in the definition of $Q_{ij}(t)$ because the off-diagonal entries of the matrix $\bar{D}_{ij}(t)$ are suppressed by the same factor proportional to \sqrt{t} that appears in (16). This suppression follows from a bound on the corresponding Dobrushin matrix of this order. Unfortunately the diagonal terms of $\bar{D}(t)$ give rise to blow-up for sites i and j that are within the range of the potential. As it is clear from the proof, this blow-up is understandable since so far we did not employ any continuity properties of the initial Hamiltonian w.r.t. the Euclidean metric. Let us mention without details that the blow-up of $\bar{D}(t)$ really occurs in a system of two sites when the Hamiltonian is a step function. This is shown by a computation and indicates that continuity of the Hamiltonian is needed.

Now, to disentangle these *local effects* from the *global effects* treated so far, we use in the third step a telescoping argument over the conditioning. Exploiting the Lipschitz-property (17) we obtain the second term in the minimum in (24) which puts a time-independent ceiling to the blow-up for small times. This solves the blow-up problem.

2.5 Gibbsianness for local approximations

As another consequence from the general theorem we prove that any sufficiently fine local coarse graining preserves the Gibbs property. Here the fineness of the coarse graining has to be compared with the scale in the local state spaces on which the initial Hamiltonian is varying.

We thus need a bit more structure, namely let (S, d) now be a metric space. Let a decomposition of S be given of the form $S = \bigcup_{\eta_i \in S'} S_{\eta_i}$. Here S' may be a finite or infinite set. Put $T(s) := \eta_i$ for $S_{\eta_i} \ni s$. This defines a deterministic transformation on S , called the *fuzzy map*. We assume that $\alpha(S_{\eta_i}) > 0$ for all η_i . For each $\eta_i \in S'$ the corresponding conditional a priori measure on S_{η_i} is given by

$$\alpha_{\eta_i}(B) = \frac{\alpha(B \cap S_{\eta_i})}{\alpha(S_{\eta_i})}. \quad (28)$$

Then our result is the following.

Theorem 2.9. *Assume the interaction Φ has the Lipschitz-property (17). Suppose further that*

$$\frac{\rho}{2} \sup_{i \in G} \sum_{j \in G} \exp\left(\frac{1}{2} \sum_{A \supset \{i,j\}} \delta(\Phi_A)\right) L_{ij} < 1$$

where $\rho = \sup_{\eta_i} \text{diam}(S_{\eta_i})$ denotes the fineness of the decomposition.

Then, for any initial Gibbs measure μ of the potential Φ with an arbitrary a priori measure α , the transformed measure $T(\mu)$ is Gibbs for a specification γ' of goodness (Q, d_0) . Here d_0 is the discrete metric and Q_{ij} is given in formula (15) where we have to substitute

$$\bar{C}_{ij} = \frac{\rho}{2} \exp\left(\frac{1}{2} \sum_{A \supset \{i,j\}} \delta(\Phi_A)\right) L_{ij}.$$

Remark 1: Answering a question of Aernout van Enter, this provides a class of examples where S and S' are different (one may be continuous, the other not), the initial measure may be in the phase transition regime, and the image measure will be Gibbs. To think of an even more concrete example, let us take the rotator-model (18). Divide the sphere $S^{q-1} = \bigcup_{\eta_i} S_{\eta_i}$ into "countries" S_{η_i} . Then the corresponding discretized model on the country-level is still Gibbs whenever there is no country with diameter bigger than $\left(\sup_i \sum_{j \in G} e^{|J_{ij}|} |J_{ij}|\right)^{-1}$.

Remark 2: Theorem 2.9 can be seen as a stability result for Gibbs measures. This is interesting, since topologically speaking "most measures are not Gibbs measures" (see section 4.5.6. [11]): Although it is true that, on the one hand translation-invariant Gibbs measures for finite range potentials on a compact metric local spin space on the lattice are dense in the space of translation-invariant probability measures w.r.t. the weak topology, they form a thin set nevertheless: Israel has proved that the set of all translation-invariant Gibbs measures is a set of first category, that is a countable union of sets which are nowhere dense (i.e. whose closure has empty interior) in all translation-invariant measures. Now, our result implies that, for any Φ with $\sup_i \sum_j L_{ij}(\Phi) < \infty$, and any fixed $\mu \in \mathcal{G}(\Phi)$ the following is true. There exists a $\rho_0 > 0$ such that the set of all $T\mu$, where T runs over all local coarse-grainings with fineness not bigger than ρ_0 , is contained in the Gibbs-measures. So we have shown that around any such Gibbs measure μ there is at least a "ball of local transforms" that lies in the Gibbs measures.

Remark 3: In fact, the theorem even holds when ρ is replaced by $\rho' < \rho$ given by

$$\rho' = \sup_{\eta_i \in S'} \inf_{a_i \in S} \left(\int \alpha_{\eta_i}(d\sigma_i) d^2(\sigma_i, a_i) \right)^{\frac{1}{2}} \quad (29)$$

which takes advantage of possible concentration of the conditional measures.

Remark 4: Let us mention that we may very well apply our method also to other well-known examples of transforms of Gibbs measures that may potentially lead to renormalization group pathologies. This could be investigated in a future paper. For instance, also the decimation transformation mapping a Gibbs measure on the lattice to its restriction to a sublattice can be cast in this framework. Theorem 2.5 then implies the statement that the projected measure is always Gibbs if the interaction is sufficiently small in triple norm. The posterior metric for configurations on the projected lattice then becomes the discrete metric $d'(\eta_i, \eta'_i) = 1_{\eta_i \neq \eta'_i}$ and hence the matrix element Q_{ij} becomes a bound on the Dobrushin interdependence matrix of the image system.

3 Proof of Theorem 2.3 and related results:

We start with the

Proof of Theorem 2.3: We begin as in the proof of Proposition 8.8 of [1], estimating the variation of the single-site measure at a given site $i \in G$ when varying the boundary

condition at some site $j \in i^c$. Fix $\zeta, \eta \in \Omega$ with $\zeta_{j^c} = \eta_{j^c}$ and put $u_0(\sigma_i) = -H_i(\sigma_i \zeta_{i^c})$ and $u_1(\sigma_i) = -H_i(\sigma_i \eta_{i^c})$. Taking linear interpolation $u_t = tu_1 + (1-t)u_0$ of u_1 and u_0 , it follows

$$\delta(u_t) \leq \delta_j(H_i). \quad (30)$$

Setting $h_t = e^{u_t}/\alpha(e^{u_t})$ and $\lambda_t(d\sigma_i) = h_t(\sigma_i)\alpha(d\sigma_i)$ we note that $\lambda_0(d\sigma_i) = \gamma_i(d\sigma_i|\zeta)$ and $\lambda_1(d\sigma_i) = \gamma_i(d\sigma_i|\eta)$. Furthermore, set $\dot{u} = u_1 - u_0$ and observe that

$$\begin{aligned} 2\|\lambda_0 - \lambda_1\| &= \int \alpha(d\sigma_i) |h_1(\sigma_i) - h_0(\sigma_i)| = \int \alpha(d\sigma_i) \left| \int_0^1 dt \frac{d}{dt} h_t(\sigma_i) \right| \\ &\leq \int_0^1 dt \lambda_t |\dot{u} - \lambda_t(\dot{u})| \leq \sup_{0 \leq t \leq 1} \lambda_t |\dot{u} - \lambda_t(\dot{u})|. \end{aligned} \quad (31)$$

Next we bring the deviation into play by writing

$$\lambda_t |\dot{u} - \lambda_t(\dot{u})| \leq 2 \inf_b \lambda_t |\dot{u} - b| \leq 2 \exp(\delta(u_t)) \inf_b \alpha |\dot{u} - b| \quad (32)$$

from which it follows by resubstituting the Hamiltonian that

$$C_{ij} \leq \exp(\delta_j(H_i)) \text{dev}_{\alpha; i, j}(H_i),$$

which also implies the desired estimate on the Dobrushin constant c .

□

One may criticize the use of oscillations in the exponent to compare the interpolating measures which is done to arrive at easily computable expressions. Of course, we are free to (numerically) compute the exact Dobrushin-matrix always. Note to this end that, writing F_i for the Boltzmann-weights at site i , i.e.

$$F_i(\sigma) = \frac{e^{-H_i(\sigma)}}{\int \alpha(d\tilde{\sigma}_i) e^{-H_i(\tilde{\sigma}_i \sigma_{i^c})}}$$

we can express the Dobrushin matrix simply as

$$C_{ij} = \frac{1}{2} \text{dev}_{\alpha; i, j}(F_i).$$

If we want to do slightly better, also the estimate

$$C_{ij} \leq \left(\sup_{\substack{\sigma, \sigma' \\ \sigma_{j^c} = \sigma'_{j^c}}} \int \alpha(d\tilde{\sigma}_i) (F_i(\tilde{\sigma}_i \sigma_{i^c}) - F_i(\tilde{\sigma}_i \sigma'_{i^c})) (H_i(\tilde{\sigma}_i \sigma_{i^c}) - H_i(\tilde{\sigma}_i \sigma'_{i^c})) \right)^{\frac{1}{2}} \quad (33)$$

can be used. The r.h.s. might be favorable in some models over the original expression for C_{ij} involving the absolute value of a difference of densities because it might lead to explicitly solvable integrals. To see the validity of (33) re-enter the proof, and use Schwartz to notice that

$$\int_0^1 dt \lambda_t |\dot{u} - \lambda_t(\dot{u})| \leq \int_0^1 dt \sqrt{\text{var}_{\lambda_t}(\dot{u})} \leq \sqrt{\int_0^1 dt \frac{d}{dt} \lambda_t(\dot{u})} = \sqrt{(\lambda_1 - \lambda_0)(\dot{u})}. \quad (34)$$

Sometimes it is useful to use quadratic variation instead of the linear variation $\text{dev}_{\alpha; i, j}$ to obtain an explicit bound, as we shall see in the proof of Theorem 2.7 below. To this end we introduce the following ‘‘quadratic variation’’.

Definition 3.1. For any bounded measurable function F on Ω and for any pair $i \neq j \in G$ the $\alpha; i, j$ -quadratic variation of F is defined by

$$\text{std}_{\alpha; i, j}(F) := \sup_{\substack{\zeta, \bar{\zeta} \in \Omega \\ \zeta_j c = \bar{\zeta}_j c}} \inf_{b \in \mathbb{R}} \left(\int \alpha(d\sigma_i) \left(F(\sigma_i \zeta_i^c) - F(\sigma_i \bar{\zeta}_i^c) - b \right)^2 \right)^{\frac{1}{2}}. \quad (35)$$

Clearly $\text{dev}_{\alpha; i, j}(F) \leq \text{std}_{\alpha; i, j}(F)$ and so we could bound the inequality in Theorem 2.3 in terms of the quadratic variation; going directly into the proof however gives us a better result as in the following "quadratic version" of Theorem 2.3.

Proposition 3.2. The Dobrushin constant c is also bounded by

$$c \leq \frac{1}{2} \sup_{i \in G} \sum_{j \in G} \exp\left(\frac{1}{2} \delta_j(H_i)\right) \text{std}_{\alpha; i, j}(H_i). \quad (36)$$

Proof: Proceed as in the proof of Theorem 2.3 but use the Schwartz inequality on

$$\lambda_t |\dot{u} - \lambda_t(\dot{u})| \leq \inf_b \left(\lambda_t |\dot{u} - b|^2 \right)^{\frac{1}{2}} \leq \exp\left(\frac{\delta(u_t)}{2}\right) \left(\text{var}_{\alpha}(\dot{u}) \right)^{\frac{1}{2}}. \quad (37)$$

□

Along these lines it is easy to obtain the following.

Corollary 3.3. If we equip the single-site space S with a metric d and the interaction Φ satisfies the Lipschitz property (17), then the Dobrushin constant c has the bound

$$c \leq \frac{1}{2} \sup_{i \in G} \sum_{j \in G} \exp\left(\frac{1}{2} \delta_j(H_i)\right) L_{ij} \inf_{a_i \in S} \left(\int d^2(\sigma_i, a_i) \alpha(d\sigma_i) \right)^{\frac{1}{2}}.$$

4 The proof of Theorem 2.5 and related results

The purpose of this section is to give the proof of Theorem 2.5 outlined in Section 2.3 of the introduction. The main ingredient to the proof is to show the lack of phase transitions in some intermediate system and exploit the consequences for the decay of spatial memory. Recall from Section 2.3 that our initial system was given by the Gibbs measure μ admitted by the specification γ obtained from the interaction Φ and an a-priori measure $\alpha(\cdot) = \int K(\cdot, d\eta_i)$ described above. Thus for a given boundary condition $\bar{\sigma}$ and any finite volume $\Lambda \subset G$ we write $\gamma_{\Lambda}(\cdot | \bar{\sigma}) \in \gamma$ as

$$\gamma_{\Lambda}(d\sigma_{\Lambda} | \bar{\sigma}) = \frac{\exp\left(-H_{\Lambda}(\sigma_{\Lambda} \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda} \alpha(d\sigma_j)}{\int_{S^{\Lambda}} \exp\left(-H_{\Lambda}(\tilde{\sigma}_{\Lambda} \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda} \alpha(d\tilde{\sigma}_j)}. \quad (38)$$

We now introduce a double-layer system or joint system by coupling the initial system to a second system (with single-spin space S') through the site-wise joint measures $K(d\sigma_i, d\eta_i)$ on

$S \times S'$. Denote by $\tilde{\gamma}$ the specification of our new double-layer system, i.e. for a fixed boundary condition $\bar{\sigma} \in \Omega$ and a finite volume $\Lambda \subset G$, $\tilde{\gamma}_\Lambda(\cdot|\bar{\sigma}) \in \tilde{\gamma}$ is given by

$$\begin{aligned} \tilde{\gamma}_\Lambda(d\sigma_\Lambda, d\eta_\Lambda|\bar{\sigma}) &= \frac{\exp\left(-H_\Lambda(\sigma_\Lambda \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda} K(d\sigma_j, d\eta_j)}{\int_{(S \times S')^\Lambda} \exp\left(-H_\Lambda(\tilde{\sigma}_\Lambda \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda} K(d\tilde{\sigma}_j, d\tilde{\eta}_j)} \\ &= \gamma_\Lambda(d\sigma_\Lambda|\bar{\sigma}) \prod_{j \in \Lambda} K(d\eta_j|\sigma_j), \end{aligned} \quad (39)$$

where $K(d\eta_i|\sigma_i)$ denotes the K conditional distribution of the second spin given the value of the first. This specification is in general not Gibbs but in our case where we only have site-wise dependence between the two layers it is known for instance from [8] and references therein that $\tilde{\gamma}$ is Gibbs.

For each non-empty subset Λ of G we denote by \mathcal{S}_Λ the collection of all non-empty finite subsets of Λ . We will write \mathcal{S} instead of \mathcal{S}_G . For any fixed configuration $\sigma \in \Omega$ and any $\Lambda \in \mathcal{S}$ we define the finite-volume *transformed* distribution $\gamma'_{\Lambda, \bar{\sigma}}$ as

$$\gamma'_{\Lambda, \bar{\sigma}}(d\eta_\Lambda) := \int_{S^\Lambda} \tilde{\gamma}(d\sigma_\Lambda, d\eta_\Lambda|\bar{\sigma}_{\Lambda^c}). \quad (40)$$

It is important to note that in the joint system considered above, conditionally on the σ 's the η 's are independent. But taking the σ -average of the joint system creates dependence among the η 's. Due to this dependence we now introduce finite-volume η conditional distributions by freezing the η configuration in the definition of $\gamma'_{\Lambda, \bar{\sigma}}$ except at some region $\Delta \in \mathcal{S}_\Lambda$. That is for any $\Lambda \in \mathcal{S}$ with $|\Lambda| \geq 2$ and $\Delta \in \mathcal{S}_\Lambda$ we have

$$\gamma'_{\Delta, \Lambda; \bar{\sigma}}(d\eta_\Delta|\bar{\eta}_{\Lambda \setminus \Delta}) = \frac{\int_{S^\Lambda} \exp\left(-H_\Lambda(\sigma_\Lambda \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda \setminus \Delta} K(d\sigma_j|\bar{\eta}_j) \prod_{i \in \Delta} K(d\sigma_i, d\eta_i)}{\int_{S^\Lambda} \exp\left(-H_\Lambda(\sigma_\Lambda \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda \setminus \Delta} K(d\sigma_j|\bar{\eta}_j) \prod_{i \in \Delta} \alpha(d\sigma_i)}. \quad (41)$$

The natural question that comes to mind is whether $\lim_{\Lambda \uparrow G} \gamma'_{\Delta, \Lambda; \bar{\sigma}}(d\eta_\Delta|\bar{\eta}_{\Lambda \setminus \Delta})$ exists for any fixed $\Delta \in \mathcal{S}_\Lambda$, $\bar{\sigma} \in \Omega$ and $\bar{\eta}_{\Delta^c} \in (S')^{\Delta^c}$? If this limit exists we will denote it by $\gamma'_\Delta(d\eta_\Delta|\bar{\eta}_{\Delta^c})$ (whose explicit form is given in (63)) and γ' by the class of all the conditional distributions for finite Δ . We shall show under some regularity conditions that γ' is a Gibbs specification. For the sake of simplicity we will always restrict our analysis to the case where Δ is a singleton. The analysis for general (but finite) Δ can be implemented by appropriately decomposing the Hamiltonian H_Λ (as given in (42)) and using the same arguments used in the singleton case. Generally, it is known for instance [1; 23] and references therein that one can construct finite-volume conditional distributions of a specification from their corresponding single-site ones. It is our aim to provide a sufficient condition for the conditional probabilities $\gamma'_{i, \Lambda; \bar{\sigma}}(d\eta_i|\bar{\eta}_{\Lambda \setminus i})$ to have an infinite-volume limit. For this we introduce the decomposition of the Hamiltonian H_Λ in the finite window Λ

into its contributions coming from the sites in $\Lambda \setminus i$ and site i for any $i \in \Lambda$ as follows;

$$\begin{aligned} H_\Lambda(\sigma_\Lambda \bar{\sigma}_{\Lambda^c}) &= H_i(\sigma_\Lambda \bar{\sigma}_{\Lambda^c}) + H_{\Lambda \setminus i}(\sigma_{\Lambda \setminus i} \bar{\sigma}_{\Lambda^c}), \quad \text{where} \\ H_i(\sigma_\Lambda \bar{\sigma}_{\Lambda^c}) &= \sum_{A \ni i} \Phi_A(\sigma_\Lambda \bar{\sigma}_{\Lambda^c}) \quad \text{and} \\ H_{\Lambda \setminus i}(\sigma_{\Lambda \setminus i} \bar{\sigma}_{\Lambda^c}) &= \sum_{A \cap \Lambda \setminus i \neq \emptyset; i \notin A} \Phi_A(\sigma_{\Lambda \setminus i} \bar{\sigma}_{\Lambda^c}). \end{aligned} \tag{42}$$

We clearly see from the definition of an interaction that the Hamiltonian $H_{\Lambda \setminus i}$ is a function on the configuration space S^{i^c} . For the infinite-volume transformed conditional distributions $\gamma'_i(d\eta_i | \eta_{i^c})$ to exist, it is sufficient that some intermediate system living on the sublattice i^c must admit a unique infinite-volume Gibbs measure. This intermediate model is what we referred to as the **restricted constrained first layer model** (defined below w.r.t $H_{\Lambda \setminus i}$).

Definition 4.1. *The **restricted constrained first layer model (RCFLM)** in any $\Lambda \in \mathcal{S}$ with $|\Lambda| \geq 2$ and $i \in \Lambda$ is defined as the measure*

$$\mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Lambda \setminus i}](d\sigma_{\Lambda \setminus i}) = \frac{\exp\left(-H_{\Lambda \setminus i}(\sigma_{\Lambda \setminus i} \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda \setminus i} K(d\sigma_j | \eta_j)}{\int_{S^{\Lambda \setminus i}} \exp\left(-H_{\Lambda \setminus i}(\tilde{\sigma}_{\Lambda \setminus i} \bar{\sigma}_{\Lambda^c})\right) \prod_{j \in \Lambda \setminus i} K(d\tilde{\sigma}_j | \eta_j)}, \tag{43}$$

for some $\bar{\sigma} = S^{i^c}$ and $\eta_\Lambda \in (S')^\Lambda$.

It is **restricted** because we only consider the spins in the sublattice i^c and **constrained** since we have frozen the configuration in the second layer. The RCFLM (as we will see from the lemma below) will provide us with a sufficient condition for the existence of an infinite-volume limit $\gamma'_i(d\eta_i | \eta_{i^c})$ for the conditional probabilities $\gamma'_{i, \Lambda; \bar{\sigma}}(d\eta_i | \eta_{\Lambda \setminus i})$.

Remark: Note that the RCFLM $\mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Lambda \setminus i}]$ is the model on the sublattice i^c corresponding to the a-priori measure α and finite-volume Hamiltonians $\bar{H}_{\Lambda \setminus i}$ given by

$$\bar{H}_{\Lambda \setminus i}(\sigma_{\Lambda \setminus i} \bar{\sigma}_{\Lambda^c}, \eta_{\Lambda \setminus i}) := H_{\Lambda \setminus i}(\sigma_{\Lambda \setminus i} \bar{\sigma}_{\Lambda^c}) - \sum_{j \in \Lambda \setminus i} \log k(\sigma_j, \eta_j). \tag{44}$$

The conditions imposed on k implies that for any given $\eta \in \Omega'$ the RCFLM results from an absolutely summable interaction guaranteeing the Gibbsianness of the RCFLM.

We state a result concerning a representation of the finite-volume conditional distributions for the transformed system in terms of the RCFLM.

Lemma 4.2. *Let $\Lambda \in \mathcal{S}$ with $|\Lambda| \geq 2$, then for any $i \in \Lambda$ and any $\bar{\sigma} \in \Omega$ we have*

$$\gamma'_{i, \Lambda; \bar{\sigma}}(d\eta_i | \eta_{\Lambda \setminus i}) = \frac{\int_{S^{\Lambda \setminus i}} \mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Lambda \setminus i}](d\sigma_{\Lambda \setminus i}) \int_S \exp\left(-H_i(\sigma_\Lambda \bar{\sigma}_{\Lambda^c})\right) K(d\sigma_i, d\eta_i)}{\int_{S^{\Lambda \setminus i}} \mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Lambda \setminus i}](d\sigma_{\Lambda \setminus i}) \int_S \exp\left(-H_i(\sigma_\Lambda \bar{\sigma}_{\Lambda^c})\right) \alpha(d\sigma_i)}. \tag{45}$$

Proof: By using the decomposition of H_Λ in (42) we can write $\gamma'_{i,\Lambda;\bar{\sigma}}(d\eta_i|\eta_{\Lambda\setminus i})$ as;

$$\begin{aligned} \gamma'_{i,\Lambda;\bar{\sigma}}(d\eta_i|\eta_{\Lambda\setminus i}) &= \\ & \frac{\int_{S^{\Lambda\setminus i}} \exp\left(-H_{\Lambda\setminus i}(\sigma_{\Lambda\setminus i}\bar{\sigma}_{\Lambda^c})\right) \prod_{j\in\Lambda\setminus i} K(d\sigma_j|\eta_j) \int_S \exp\left(-H_i(\sigma_\Lambda\bar{\sigma}_{\Lambda^c})\right) K(d\sigma_i, d\eta_i)}{\int_{S^{\Lambda\setminus i}} \exp\left(-H_{\Lambda\setminus i}(\sigma_{\Lambda\setminus i}\bar{\sigma}_{\Lambda^c})\right) \prod_{j\in\Lambda\setminus i} K(d\sigma_j|\eta_j) \int_{S\times S'} \exp\left(-H_i(\sigma_\Lambda\bar{\sigma}_{\Lambda^c})\right) K(d\sigma_i, d\tilde{\eta}_i)}. \end{aligned} \quad (46)$$

The claim of the lemma follows by multiplying the expression for $\gamma'_{i,\Lambda;\bar{\sigma}}(d\eta_i|\eta_{\Lambda\setminus i})$ above by $\frac{\int_{S^{\Lambda\setminus i}} \exp\left(-H_{\Lambda\setminus i}(\tilde{\sigma}_{\Lambda\setminus i}\bar{\sigma}_{\Lambda^c})\right) \prod_{j\in\Lambda\setminus i} K(d\tilde{\sigma}_j|\eta_j)}{\int_{S^{\Lambda\setminus i}} \exp\left(-H_{\Lambda\setminus i}(\tilde{\sigma}_{\Lambda\setminus i}\bar{\sigma}_{\Lambda^c})\right) \prod_{j\in\Lambda\setminus i} K(d\tilde{\sigma}_j|\eta_j)}$ and simplifying the resulting expression. □

The above lemma can easily be extended to any finite subset $\Gamma \in \mathcal{S}_\Lambda$ to obtain

$$\gamma'_{\Gamma,\Lambda;\bar{\sigma}}(d\eta_\Gamma|\eta_{\Lambda\setminus\Gamma}) = \frac{\int_{S^{\Lambda\setminus\Gamma}} \mu_{\Lambda\setminus\Gamma}^{\bar{\sigma}}[\eta_{\Lambda\setminus\Gamma}](d\sigma_{\Lambda\setminus\Gamma}) \int_{S^\Gamma} \exp\left(-H_\Gamma(\sigma_\Lambda\bar{\sigma}_{\Lambda^c})\right) \prod_{i\in\Gamma} K(d\sigma_i, d\eta_i)}{\int_{S^{\Lambda\setminus\Gamma}} \mu_{\Lambda\setminus\Gamma}^{\bar{\sigma}}[\eta_{\Lambda\setminus\Gamma}](d\sigma_{\Lambda\setminus\Gamma}) \int_{S^\Gamma} \exp\left(-H_\Gamma(\sigma_\Lambda\bar{\sigma}_{\Lambda^c})\right) \prod_{i\in\Gamma} \alpha(d\sigma_i)}. \quad (47)$$

As an immediate consequence of the above lemma we fix the following infinite-volume result concerning the existence of the infinite-volume kernel $\gamma'_i(d\eta_i|\eta_{i^c})$.

Proposition 4.3. *Suppose Λ_n is a sequence of finite subsets of G with $\Lambda_n \rightarrow G$ as n tends to infinity, $\bar{\sigma} \in S^{i^c}$ and $\eta \in S^{i^c}$ are such that RCFLM $\mu_{\Lambda_n\setminus i}^{\bar{\sigma}}[\eta_{\Lambda_n\setminus i}]$ has an infinite-volume limit $\mu_{i^c}^{\bar{\sigma}}[\eta_{i^c}]$ (in the quasilocal topology, i.e. on uniform limits of local functions). Then the single-site finite-volume conditional distribution $\gamma'_{i,\Lambda_n;\bar{\sigma}}(d\eta_i|\eta_{\Lambda_n\setminus i})$ for the transformed system has an infinite-volume limit $\gamma'_{i,\bar{\sigma}}(d\eta_i|\eta_{i^c})$ given by*

$$\gamma'_{i,\bar{\sigma}}(d\eta_i|\eta_{i^c}) = \frac{\int_{S^{i^c}} \mu_{i^c}^{\bar{\sigma}}[\eta_{i^c}](d\sigma_{i^c}) \int_S \exp\left(-H_i(\sigma)\right) K(d\sigma_i, d\eta_i)}{\int_{S^{i^c}} \mu_{i^c}^{\bar{\sigma}}[\eta_{i^c}](d\sigma_{i^c}) \int_S \exp\left(-H_i(\sigma)\right) d\alpha(\sigma_i)}. \quad (48)$$

For each η configuration the family of finite-volume conditional distributions $\mu_{\Lambda\setminus i}^{\bar{\sigma}}[\eta_{\Lambda\setminus i}]$ constitutes a quasilocal specification guaranteeing the hypothesis of the above proposition. The assertion of the proposition follows immediately from Lemma 4.2 and the choice of topology.

A similar statement is observed in the corresponding general mean-field set-up in [18] where also a sufficient condition for the existence of infinite-volume transformed kernels is given in terms of the uniqueness of global minimizers for a (constrained) rate function. We now state a result concerning an upper bound on Dobrushin's constant for the RCFLM.

Proposition 4.4. *Let the Dobrushin's interdependence matrix for the RCFLM on i_o^c for some fixed site $i_o \in G$ be the matrix whose entries are given by*

$$C_{ij}^{i_o}[\eta_i] = \sup_{\zeta, \bar{\zeta} \in S^{i_o^c}; \zeta_{j^c} = \bar{\zeta}_{j^c}} \left\| \mu_i^\zeta[\eta_i] - \mu_i^{\bar{\zeta}}[\eta_i] \right\|, \quad (49)$$

for any pair $i, j \in i_o^c$ where we have denoted $\mu_i^{\bar{c}}$ by the single-site part of $\mu_{\Lambda \setminus i_o}^{\bar{c}}$.
Then we have;

$$C_{ij}^{i_o}[\eta_i] \leq \exp\left(\sum_{A \supset \{i,j\}; i_o \notin A} \delta(\Phi_A)\right) \text{dev}_{\alpha_{\eta_i}; i,j}(H_i), \quad (50)$$

where $\alpha_{\eta_i}(d\sigma_i) = K(d\sigma_i | \eta_i)$.

Furthermore, defining the Dobrushin constant $c'[\eta]$ for the RCFLM as

$$c'[\eta] := \sup_{i_o \in G} c^{i_o}[\eta], \quad \text{with } c^{i_o}[\eta] = \sup_{i \in i_o^c} \sum_{j \in i_o^c} C_{ij}^{i_o}[\eta_i], \quad (51)$$

we also have

$$\begin{aligned} c'[\eta] &\leq \sup_{i_o \in G} \sup_{i \in i_o^c} \sum_{j \in i_o^c} \exp\left(\sum_{A \supset \{i,j\}; i_o \notin A} \delta(\Phi_A)\right) \text{dev}_{\alpha_{\eta_i}; i,j}(H_i) \\ &\leq \sup_{i \in G} \sum_{j \in G} \exp\left(\sum_{A \supset \{i,j\}} \delta(\Phi_A)\right) \text{dev}_{\alpha_{\eta_i}; i,j}(H_i). \end{aligned} \quad (52)$$

Additionally, if a notion of translation can be defined on G and the initial interaction is translation-invariant, then the last inequality is an equality.

Proof: The proof follows the same lines as the proof of Theorem 2.3 but here we use $\alpha_{\eta_i} = K(\cdot | \eta_i)$ instead of α .

□

It is also not hard to deduce from Proposition 3.2 that;

$$\begin{aligned} c'[\eta] &\leq \frac{1}{2} \sup_{i_o \in G} \sup_{i \in i_o^c} \sum_{j \in i_o^c} \exp\left(\frac{1}{2} \sum_{A \supset \{i,j\}; i_o \notin A} \delta(\Phi_A)\right) \text{std}_{\alpha_{\eta_i}; i,j}(H_i) \\ &\leq \frac{1}{2} \sup_{i \in G} \sum_{j \in G} \exp\left(\frac{1}{2} \sum_{A \supset \{i,j\}} \delta(\Phi_A)\right) \text{std}_{\alpha_{\eta_i}; i,j}(H_i). \end{aligned} \quad (53)$$

Again Lipschitzness of the initial Hamiltonian carries over nicely to yield;

Corollary 4.5. *Suppose that H_i satisfies the Lipschitz-condition (17). Then we have*

$$\begin{aligned} c'[\eta] &= \sup_{i_o \in G} \sup_{i \in i_o^c} \sum_{j \in i_o^c} C_{ij}^{i_o}[\eta_i] \\ &\leq \frac{1}{2} \sup_{i_o \in G} \sup_{i \in i_o^c} \sum_{j \in i_o^c} \exp\left(\frac{1}{2} \sum_{A \supset \{i,j\}; i_o \notin A} \delta(\Phi_A)\right) L_{ij} \inf_{a_i \in S} \left(\int_S d^2(\sigma_i, a_i) \alpha_{\eta_i}(d\sigma_i)\right)^{\frac{1}{2}} \\ &\leq \frac{1}{2} \sup_{i \in G} \sum_{j \in G} \exp\left(\frac{1}{2} \sum_{A \supset \{i,j\}} \delta(\Phi_A)\right) L_{ij} \inf_{a_i \in S} \left(\int_S d^2(\sigma_i, a_i) \alpha_{\eta_i}(d\sigma_i)\right)^{\frac{1}{2}}. \end{aligned} \quad (54)$$

The claim of the corollary follows from Corollary 3.3.

We now proceed to prove Theorem 2.5, but before we do this we still need some results from which the proof will follow. As a first step we recall some known results about Dobrushin's uniqueness concerning an estimate of the distance between the unique Gibbs measure admitted by a Gibbs specification satisfying Dobrushin's condition and another Gibbs measure corresponding to some other specification. This estimate tells us the local variation between the two infinite-volume probability measures. This result which we state in the proposition below can be found for example in [1] as Theorem 8.20. Before we state this result let us fix some notations. Suppose $C(\gamma)$ is the Dobrushin interdependence matrix of a specification γ and $C^n(\gamma)$, $n \geq 0$, the n 'th power of $C(\gamma)$, then we define the matrix

$$D(\gamma) = (D_{ij})_{i,j \in G} := \sum_{n \geq 0} C^n(\gamma). \quad (55)$$

Proposition 4.6. *Let γ and $\bar{\gamma}$ be any two specifications with γ satisfying Dobrushin's condition. Suppose that for each $i \in G$ we have a measurable function b_i on the standard Borel space Ω with the property that*

$$\|\gamma_i(\cdot|\sigma_{i^c}) - \bar{\gamma}_i(\cdot|\sigma_{i^c})\| \leq b_i(\sigma) \quad (56)$$

for all $\sigma \in \Omega$. Then for $\mu \in \mathcal{G}(\gamma)$ and $\bar{\mu} \in \mathcal{G}(\bar{\gamma})$ we have

$$|\mu(f) - \bar{\mu}(f)| \leq \sum_{i,j \in G} \delta_i(f) D_{ij}(\gamma) \bar{\mu}(b_j) \quad (57)$$

for all quasilocal functions f .

Observe from Proposition 4.3 that if the RCFLM satisfies Dobrushin's condition uniformly in η the infinite-volume single-site kernels $\gamma'_i(\cdot|\eta_i^c)$ exist for every η independent of the boundary conditions used for the initial system. We will adapt the result in Proposition 4.6 to our present set-up to compare $\gamma'_i(\cdot|\eta_i^c)$ and $\gamma'_i(\cdot|\bar{\eta}_i^c)$ for any pair of configurations $\eta, \bar{\eta} \in \Omega' = (S')^G$. Further we denote by $\gamma[\eta_i^c]$ the specification of the RCFLM with full η_i^c configuration. Again we assume for the first-layer model that $\mu = \lim_n \mu_{\Lambda_n}^{\bar{\sigma}}$ as in the hypothesis of Theorem 2.5.

Proposition 4.7. *Suppose the RCFLM on the sublattice i^c (for some $i \in G$) satisfies Dobrushin's condition uniformly in η with unique infinite-volume limit $\mu_{i^c}[\eta_i^c]$. Then*

1. *The second-layer system (the transformed model) has infinite-volume single-site conditional distributions $\gamma'_i(d\eta_i|\eta_i^c)$ given by*

$$\gamma'_i(d\eta_i|\eta_i^c) = \frac{\int_{S^{i^c}} \mu_{i^c}[\eta_i^c](d\sigma_{i^c}) \int_S \exp\left(-H_i(\sigma_i \sigma_{i^c})\right) K(d\sigma_i, d\eta_i)}{\int_{S^{i^c}} \mu_{i^c}[\eta_i^c](d\sigma_{i^c}) \int_S \exp\left(-H_i(\sigma_i \sigma_{i^c})\right) \alpha(d\sigma_i)}. \quad (58)$$

2. *For any pair $\eta_i^c, \bar{\eta}_i^c \in (S')^{i^c}$ we have for any $j \neq i$ that*

$$\left\| \gamma_j[\eta_j](\cdot|\bar{\sigma}_{i^c}) - \gamma_j[\bar{\eta}_j](\cdot|\bar{\sigma}_{i^c}) \right\| \leq 2 \exp\left(\sum_{A \ni j} \delta_j(\Phi_A)\right) \left\| K(\cdot|\eta_j) - K(\cdot|\bar{\eta}_j) \right\|, \quad (59)$$

where the $\gamma_j[\eta_j](\cdot|\bar{\sigma}_{i^c})$'s are the single-site parts of the specification for the RCFLM for $i \in G$ and η_i^c .

3. Given

$$h_2(\sigma_{i^c}) = \int_S \alpha(d\sigma_i) \exp\left(H_i(\sigma_i \sigma_{i^c})\right)$$

it follows that

$$\begin{aligned} & \left| \mu_{i^c}[\eta_{i^c}](h_2) - \mu_{i^c}[\bar{\eta}_{i^c}](h_2) \right| \leq 2e^{\sum_{A \ni i} \|\Phi_A\|_\infty} \\ & \times \sum_{k, j \in i^c} \delta_k \left(\sum_{A \supset \{i, k\}} \Phi_A \right) \bar{D}_{kj} \exp\left(\sum_{A \ni j} \delta_j(\Phi_A)\right) \left\| K(\cdot | \eta_j) - K(\cdot | \bar{\eta}_j) \right\|. \end{aligned} \quad (60)$$

4. Furthermore, for any $k \neq i$ it is the case that

$$\delta_k\left(h_2(\sigma_{i^c})\right) \leq \delta_k\left(\sum_{A \ni i, k} \Phi_A\right) e^{\sum_{A \ni i} \|\Phi_A\|_\infty}. \quad (61)$$

5. And finally

$$\left\| \gamma'_i(d\eta_i | \eta_{i^c}) - \gamma'_i(d\eta_i | \bar{\eta}_{i^c}) \right\| \leq 2 \frac{\left| \mu_{i^c}[\eta_{i^c}](h_2) - \mu_{i^c}[\bar{\eta}_{i^c}](h_2) \right|}{\mu_{i^c}[\bar{\eta}_{i^c}](h_2)}. \quad (62)$$

Remark: In particular, we can write for any finite volume the corresponding relation for the finite-volume conditional distribution for the transformed system with full η -conditioning as in (58), i.e. if $\Delta \in \mathcal{S}$ then we have

$$\gamma'_\Delta(d\eta_\Delta | \eta_{\Delta^c}) = \frac{\int_{S^{\Delta^c}} \mu_{\Delta^c}[\eta_{\Delta^c}](d\sigma_{\Delta^c}) \int_{S^\Delta} \exp\left(-H_\Delta(\sigma_\Delta \sigma_{\Delta^c})\right) \prod_{i \in \Delta} K(d\sigma_i, d\eta_i)}{\int_{S^{\Delta^c}} \mu_{\Delta^c}[\eta_{\Delta^c}](d\sigma_{\Delta^c}) \int_{S^\Delta} \exp\left(-H_\Delta(\sigma_\Delta \sigma_{\Delta^c})\right) \prod_{i \in \Delta} \alpha(d\sigma_i)}. \quad (63)$$

This form follows by starting from a finite-volume say Λ which contains Δ and decompose the Hamiltonian H_Λ as in (42) but this time i has to be replaced with Δ . Generally one can construct non-singleton parts of a specification from their single-site ones [1; 23].

Proof of Proposition 4.7: We will prove the assertions of the proposition in the following order: 4, 5, 1, 2 and 3.

4. Recalling that

$$h_2(\sigma_{i^c}) = \int_S \alpha(d\sigma_i) \exp\left(-H_i(\sigma_i \sigma_{i^c})\right),$$

we estimate for any pair of configurations σ and $\bar{\sigma}$ that coincide except at site k that

$$\begin{aligned} & \left| \exp\left(-H_i(\sigma_i \sigma_{i^c})\right) - \exp\left(-H_i(\sigma_i \bar{\sigma}_{i^c})\right) \right| \\ & = \left| \exp\left(-\sum_{A \ni i, k} \Phi_A(\sigma_i \sigma_{i^c})\right) - \exp\left(-\sum_{A \ni i, k} \Phi_A(\sigma_i \bar{\sigma}_{i^c})\right) \right| \exp\left(-\sum_{A \ni i, A \not\ni k} \Phi_A(\sigma_i \sigma_{i^c})\right) \\ & \leq \delta_k \left(\sum_{A \ni i, k} \Phi_A \right) e^{\sum_{A \ni i} \|\Phi_A\|_\infty}, \end{aligned} \quad (64)$$

where we have used the fact that $|e^x - e^y| \leq |x - y|e^{\max\{x,y\}}$.

5. Take a measurable function $\varphi : S' \rightarrow \mathbb{R}$, with $|\varphi| \leq 1$ and consider

$$\begin{aligned} & \int_{S'} \varphi(\eta_i) \left(\gamma'_i(d\eta_i|\eta_{i^c}) - \gamma'_i(d\eta_i|\bar{\eta}_{i^c}) \right) \\ &= \frac{\int_{S^{i^c}} \mu_{i^c}[\eta_{i^c}](d\sigma_{i^c}) h_1(\sigma_{i^c})}{\int_{S^{i^c}} \mu_{i^c}[\eta_{i^c}](d\sigma_{i^c}) h_2(\sigma_{i^c})} - \frac{\int_{S^{i^c}} \mu_{i^c}[\bar{\eta}_{i^c}](d\sigma_{i^c}) h_1(\sigma_{i^c})}{\int_{S^{i^c}} \mu_{i^c}[\bar{\eta}_{i^c}](d\sigma_{i^c}) h_2(\sigma_{i^c})}, \end{aligned} \quad (65)$$

where we have set

$$h_1(\sigma_{i^c}) = \int_{S \times S'} K(d\sigma_i, d\eta_i) \varphi(\eta_i) \exp\left(-H_i(\sigma_i, \sigma_{i^c})\right).$$

By adding and subtracting

$$\frac{\mu_{i^c}[\eta_{i^c}](h_1) \mu_{i^c}[\eta_{i^c}](h_2)}{\mu_{i^c}[\eta_{i^c}](h_2) \mu_{i^c}[\bar{\eta}_{i^c}](h_2)}$$

to the right hand side of (65) and making use of the fact that $\|\varphi\|_\infty \leq 1$ (after an application of the triangle inequality and Fubini's theorem) yield

$$\left| \int_{S'} \varphi(\eta_i) \left(\gamma'_i(d\eta_i|\eta_{i^c}) - \gamma'_i(d\eta_i|\bar{\eta}_{i^c}) \right) \right| \leq 2 \frac{\left| \mu_{i^c}[\eta_{i^c}](h_2) - \mu_{i^c}[\bar{\eta}_{i^c}](h_2) \right|}{\mu_{i^c}[\bar{\eta}_{i^c}](h_2)}. \quad (66)$$

Note that we made no use of the item 2 of the proposition to arrive at this bound.

1. The proof follows from a two-step limiting procedure. We fix an η -conditioning only in a finite volume Γ and construct the infinite-volume measure of the RCFLM by fixing a boundary condition on the first layer outside Λ (which we assume for simplicity to contain Γ) and let Λ tend to infinity. Then we let Γ also tend to infinity, and recover the conditional probabilities by Martingale convergence and uniform approximation of the infinite-volume RCFLM, with conditionings only in volume Γ .

More precisely, it follows as in Lemma 4.2 that we have for finite-volume conditionings the representation

$$\gamma'_{i,\Gamma,\Lambda,\bar{\sigma}}(d\eta_i|\eta_{\Gamma \setminus i}) = \frac{\mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Gamma \setminus i}] \left[\int_S e^{-H_i(\sigma_i, \bar{\sigma}_{\Lambda^c \setminus \Lambda \setminus i})} K(d\sigma_i, d\eta_i) \right]}{\mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Gamma \setminus i}] \left[\int_S e^{-H_i(\sigma_i, \bar{\sigma}_{\Lambda^c \setminus \Lambda \setminus i})} \alpha(d\sigma_i) \right]}. \quad (67)$$

On the r.h.s. we see a RCFLM $\mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Gamma \setminus i}]$ appearing with constrained measure α_{η_i} only in the volume $\Gamma \setminus i$, i.e.

$$\mu_{\Lambda \setminus i}^{\bar{\sigma}}[\eta_{\Gamma \setminus i}](d\sigma_\Lambda) = \frac{e^{-H_{\Lambda \setminus i}(\sigma_{\Lambda \setminus i}, \bar{\sigma}_{\Lambda^c})} \prod_{j \in \Gamma \setminus i} K(d\sigma_j|\eta_j) \prod_{k \in \Lambda \setminus \Gamma} \alpha(d\sigma_k)}{\int_{S^{\Lambda \setminus i}} e^{-H_{\Lambda \setminus i}(\tilde{\sigma}_{\Lambda \setminus i}, \bar{\sigma}_{\Lambda^c})} \prod_{j \in \Gamma \setminus i} K(d\tilde{\sigma}_j|\eta_j) \prod_{k \in \Lambda \setminus \Gamma} \alpha(d\tilde{\sigma}_k)}. \quad (68)$$

As was shown above the RCFLM has an infinite-volume limit even when there is full η conditioning, so in this case where we have conditioning only in a finite region there is no issue with

the existence of an infinite-volume limit. Hence, the conditional distribution $\gamma'_{i,\Lambda,\bar{\sigma}}(d\eta_i|\eta_{\Gamma\setminus i})$ has an infinite-volume limit $\gamma'_{i,\bar{\sigma}}(d\eta_i|\eta_{\Gamma\setminus i})$, for any arbitrary conditioning $\eta_{\Gamma\setminus i}$, since

$$h(\sigma_{\Lambda\setminus i}\bar{\sigma}_{\Lambda^c}, \eta_i) := \int_S e^{-H_i(\sigma_{\Lambda}\bar{\sigma}_{\Lambda^c})} k(\sigma_i, \eta_i) \alpha(d\sigma_i)$$

is a bounded quasilocal function in σ for each η_i . Note that this conditional distribution still depends on the boundary condition $\bar{\sigma}$ when the initial specification is in the phase transition regime. Let us denote the corresponding specification of the RCFLM with η -conditioning only in $\Gamma \setminus i$ by $\gamma[\eta_{\Gamma\setminus i}]$. It follows from the arguments leading to the proof of (62) that

$$\begin{aligned} & \left\| \gamma'_{i,\bar{\sigma}}(d\eta_i|\eta_{\Gamma\setminus i}) - \gamma'_i(d\eta_i|\eta_i^c) \right\| \\ & \leq 2 \frac{\left| \mu_{i^c}[\eta_{\Gamma\setminus i}] \left[\int_{S'} h(\cdot, \eta_i) \alpha'(d\eta_i) \right] - \mu_{i^c}[\eta_i^c] \left[\int_{S'} h(\cdot, \eta_i) \alpha'(d\eta_i) \right] \right|}{\mu_{i^c}[\eta_i^c] \left[\int_{S'} h(\cdot, \eta_i) \alpha'(d\eta_i) \right]}. \end{aligned} \quad (69)$$

Observe further that

$$\|\gamma_j[\eta_{\Gamma\setminus i}] - \gamma_j[\eta_i^c]\| \begin{cases} = 0 & \text{if } j \in \Gamma \setminus i; \\ \leq 2 & \text{if } j \in \Gamma^c. \end{cases} \quad (70)$$

By using the above inequality and the following facts: (1) for each η configuration the family of finite-volume conditional distributions for the RCFLM is a quasilocal specification, (2) the assumption that the RCFLM with full η -conditioning satisfies Dobrushin's condition uniformly in η and (3) the comparison criterion in Proposition 4.6 we obtain

$$\begin{aligned} & \left| \mu_{i^c}[\eta_{\Gamma\setminus i}] \left[\int_{S'} h(\cdot, \eta_i) \alpha'(d\eta_i) \right] - \mu_{i^c}[\eta_i^c] \left[\int_{S'} h(\cdot, \eta_i) \alpha'(d\eta_i) \right] \right| \\ & \leq 2 \sum_{i \in G} \sum_{j \in \Gamma^c} \delta_i \left(\int_{S'} h(\cdot, \eta_i) \alpha'(d\eta_i) \right) \bar{D}_{ij}. \end{aligned} \quad (71)$$

Note that in the above we have taken $\mu_{i^c}[\eta_{\Gamma\setminus i}]$ and $\mu_{i^c}[\eta_i^c]$ to be the infinite-volume Gibbs measures for the RCFLM with η -conditioning in $\Gamma \setminus i$ and i^c respectively.

Taking now the limit $\Gamma \uparrow G$ we get (58), by local convergence of the RCFLM in Γ to the full one, and by the backwards martingale convergence theorem (see p.472 [26]).

2. The proof of assertion 2 uses the definition of the single-site part of the RCFLM and arbitrary measurable function $g : \Omega \rightarrow \mathbb{R}$, with $|g| \leq 1$ to define

$$\left| \int g(\sigma_j) \left(\gamma_j[\eta_j](d\sigma_j|\bar{\sigma}_{i^c}) - \gamma_j[\bar{\eta}_j](d\sigma_j|\bar{\sigma}_{i^c}) \right) \right|. \quad (72)$$

The rest of the proof follows by adding and subtracting the following quantity

$$\frac{\int g(\sigma_j) \exp\left(-H_j(\sigma_j \bar{\sigma}_{\{i,j\}^c})\right) K(d\sigma_j|\eta_j) \int \exp\left(-H_j(\bar{\sigma}_j \bar{\sigma}_{\{i,j\}^c})\right) K(d\bar{\sigma}_j|\eta_j)}{\int \exp\left(-H_j(\bar{\sigma}_j \bar{\sigma}_{\{i,j\}^c})\right) K(d\bar{\sigma}_j|\bar{\eta}_j) \int \exp\left(-H_j(\bar{\sigma}_j \bar{\sigma}_{\{i,j\}^c})\right) K(d\bar{\sigma}_j|\eta_j)} \quad (73)$$

to the expression under the absolute value sign in (72), rearranging terms and simplifying appropriately.

3. It follows from (56) and (57) of Proposition 4.6 that

$$\left| \mu_{i^c}[\eta_{i^c}](h_2) - \mu_{i^c}[\bar{\eta}_{i^c}](h_2) \right| \leq 2 \sum_{k,j \in i^c} \delta_k(h_2) \bar{D}_{kj} \exp\left(\sum_{A \ni j} \delta_j(\Phi_A) \right) \left\| K(\cdot|\eta_j) - K(\cdot|\bar{\eta}_j) \right\|, \quad (74)$$

since by definition of H_i , h_2 is a quasilocal function on S^{i^c} . The rest of the proof of 3 follows from the bound on $\delta_k(h_2)$ given in statement 4 of the Proposition. \square

Note from the proof of statement 5 of the above Proposition that the denominator in (66) can as well be $\mu_{i^c}[\eta_{i^c}](h_2)$ if one adds and subtracts from the right hand side of (65) $\frac{\mu_{i^c}[\bar{\eta}_{i^c}](h_1)\mu_{i^c}[\bar{\eta}_{i^c}](h_2)}{\mu_{i^c}[\eta_{i^c}](h_2)\mu_{i^c}[\bar{\eta}_{i^c}](h_2)}$ instead of $\frac{\mu_{i^c}[\eta_{i^c}](h_1)\mu_{i^c}[\eta_{i^c}](h_2)}{\mu_{i^c}[\eta_{i^c}](h_2)\mu_{i^c}[\bar{\eta}_{i^c}](h_2)}$, as was the case in the above proof. But any of the two makes no difference since in our estimate we don't make use of the actual integral of h_2 but instead we utilize its uniform norm. Having disposed of the results above, we now return to the

Proof of Theorem 2.5: We divide the proof into two steps; namely, (1) we proof that the class γ' is a Gibbsian specification and (2) justify the form of the goodness of γ' as given in the theorem. We start with the proof of the latter.

2. Using the arguments leading to the proofs (62) and (60) of Proposition 4.7 we get

$$\begin{aligned} \left\| \gamma'_i(d\eta_i|\eta_{i^c}) - \gamma'_i(d\eta_i|\bar{\eta}_{i^c}) \right\| &\leq 2 \frac{\left| \mu_{i^c}[\eta_{i^c}](h_2) - \mu_{i^c}[\bar{\eta}_{i^c}](h_2) \right|}{\mu_{i^c}[\bar{\eta}_{i^c}](h_2)} \\ &\leq 4e^{2\sum_{A \ni i} \|\Phi_A\|_\infty} \sum_{k,j \in i^c} \delta_k \left(\sum_{A \supset \{i,k\}} \Phi_A \right) \bar{D}_{kj} e^{\sum_{A \ni j} \delta_j(\Phi_A)} \left\| K(\cdot|\eta_j) - K(\cdot|\bar{\eta}_j) \right\|. \end{aligned} \quad (75)$$

The 2 in front of $\sum_{A \ni i} \|\Phi_A\|_\infty$ in the exponential is obtained by observing that $\frac{1}{\mu_{i^c}[\bar{\eta}_{i^c}](h_2)} \leq \frac{1}{e^{-\sum_{A \ni i} \|\Phi_A\|_\infty}}$.

1. We now show that γ' is a Gibbsian specification, i.e. we have to show that

(i) for each finite-volume Λ and measurable set $A \in \Omega'$, $\gamma'_\Lambda(A|\cdot)$ is \mathcal{F}'_{Λ^c} -measurable (\mathcal{F}'_{Λ^c} is the σ -algebra of events in Ω' determined by spins outside Λ),

(ii) for each $\eta \in S'^{\Lambda^c}$ $\gamma'_\Lambda(\cdot|\eta)$ is a probability measure on (Ω', \mathcal{F}') ,

(iii) for each $\eta \in S'^{\Lambda^c}$ and $B \in \mathcal{F}'_{\Lambda^c}$, $\gamma'_\Lambda(B|\eta) = 1_B(\eta)$ (properness),

(iv) for any finite volumes Λ and Δ such that $\Lambda \subset \Delta$, $\gamma'_\Delta \gamma'_\Lambda = \gamma'_\Delta$ (consistency),

(v) for any bounded measurable quasilocal function $f : \Omega' \rightarrow \mathbb{R}$, $\gamma'_\Lambda(f|\cdot)$ is quasilocal for all finite-volumes Λ and

(vi) for each finite volume Λ there are constants $0 < v_\Lambda \leq u_\Lambda < \infty$ such that

$v_\Lambda \alpha'^\Lambda(A) \leq \gamma'_\Lambda(A|\eta) \leq u_\Lambda \alpha'^\Lambda(A)$, for all $\eta \in \Omega'$ and measurable subsets $A \in \mathcal{F}'_\Lambda$, (uniform non-nullness).

Note that for $\Gamma \subset \Lambda$, γ'_Γ is obtained by taking $\Lambda \uparrow G$ limit of the conditional distribution $\gamma'_{\Gamma, \Lambda; \bar{\sigma}}(d\eta_\Gamma | \eta_{\Lambda \setminus \Gamma})$ (47). It follows from the conditions imposed on the joint a-priori measure K that the class of conditional distributions $\gamma'_{\Gamma, \Lambda; \bar{\sigma}}$, satisfies (i) to (iv) and consequently γ' also satisfies (i) to (iv). Thus γ' is a specification.

(v) We are now show that γ' is quasilocal, i.e. we need to show that for any bounded quasilocal observable f and any configuration $\eta \in \Omega'$

$$\limsup_{\Lambda \uparrow G} \sup_{\bar{\eta} \in \Omega'} \left| \gamma'_\Gamma(f | \eta_\Lambda \bar{\eta}) - \gamma'_\Gamma(f | \eta) \right| = 0 \quad (76)$$

for all finite-volumes Γ . So for any bounded quasilocal observable f observe from (7) that

$$\left| \gamma'_\Gamma(f | \eta_\Lambda \bar{\eta}) - \gamma'_\Gamma(f | \eta) \right| \leq \delta(f) \left\| \gamma'_\Gamma(\cdot | \eta_\Lambda \bar{\eta}) - \gamma'_\Gamma(\cdot | \eta) \right\|. \quad (77)$$

But for any of such Γ observe from the proof of (62) and (60) of Proposition 4.7 and the proof of assertion 2 of this theorem that

$$\begin{aligned} \left\| \gamma'_\Gamma(\cdot | \eta_\Lambda \bar{\eta}_{\Lambda^c}) - \gamma'_\Gamma(\cdot | \eta) \right\| &\leq 2 \frac{\left| \mu_{\Gamma^c}[\eta_{\Lambda \setminus \Gamma} \bar{\eta}_{\Lambda^c}](\hat{h}_2) - \mu_{\Gamma^c}[\eta_{\Gamma^c}](\hat{h}_2) \right|}{\mu_{\Gamma^c}[\bar{\eta}_{\Gamma^c}](\hat{h}_2)} \\ &\leq 4e^{2 \sum_{A \cap \Gamma \neq \emptyset} \|\Phi_A\|_\infty} \sum_{k, j \in \Lambda^c} \delta_k \left(\sum_{A; A \cap \Gamma \neq \emptyset, A \ni k} \Phi_A \right) \bar{D}_{kj} e^{\sum_{A \ni j} \delta_j(\Phi_A)} \left\| K(\cdot | \bar{\eta}_j) - K(\cdot | \eta_j) \right\|, \end{aligned} \quad (78)$$

$$\text{where } \hat{h}_2(\sigma_{\Gamma^c}) = \int_{S^\Gamma} \prod_{i \in \Gamma} \alpha(d\sigma_i) \exp \left(- H_\Gamma(\sigma_\Gamma \sigma_{\Gamma^c}) \right).$$

(vi) It follows from (63) that for any finite volume Δ , γ'_Δ is given by

$$\gamma'_\Delta(d\eta_\Delta | \eta_{\Delta^c}) = \frac{\int_{S^{\Delta^c}} \mu_{\Delta^c}[\eta_{\Delta^c}](d\sigma_{\Delta^c}) \int_{S^\Delta} \exp \left(- H_\Delta(\sigma_\Delta \sigma_{\Delta^c}) \right) \prod_{i \in \Delta} K(d\sigma_i, d\eta_i)}{\int_{S^{\Delta^c}} \mu_{\Delta^c}[\eta_{\Delta^c}](d\sigma_{\Delta^c}) \int_{S^\Delta} \exp \left(- H_\Delta(\sigma_\Delta \sigma_{\Delta^c}) \right) \prod_{i \in \Delta} \alpha(d\sigma_i)}. \quad (79)$$

It follows from the hypothesis on the joint a-priori measure K that for any $A \in \mathcal{F}'_\Delta$ and any $\eta \in \Omega'$ that

$$\begin{aligned} \gamma'_\Delta(A | \eta_{\Delta^c}) &\leq \exp(\delta(H_\Delta)) \alpha'^\Delta(A) \quad \text{and} \\ \gamma'_\Delta(A | \eta_{\Delta^c}) &\geq \exp(-\delta(H_\Delta)) \alpha'^\Delta(A). \end{aligned} \quad (80)$$

This proves the uniform non-nullness of γ' since the interactions defining the Hamiltonian H_Δ is quasilocal.

□

It follows from the proof of Theorem 2.5 that for any finite-volume Γ , whenever the RCFLM satisfies Dobrushin's condition uniformly in η then we have the following continuity estimates for γ'_Γ

$$\begin{aligned} & \left\| \gamma'_\Gamma(d\eta_\Gamma | \eta_{\Gamma^c}) - \gamma'_\Gamma(d\eta_\Gamma | \bar{\eta}_{\Gamma^c}) \right\| \\ & \leq 4e^{2\sum_{A \cap \Gamma \neq \emptyset} \|\Phi_A\|_\infty} \sum_{k, j \in \Gamma^c} \delta_k \left(\sum_{A: A \cap \Gamma \neq \emptyset, A \ni k} \Phi_A \right) \bar{D}_{kj} e^{\sum_{A \ni j} \delta_j(\Phi_A)} \left\| K(\cdot | \eta_j) - K(\cdot | \bar{\eta}_j) \right\|. \end{aligned} \quad (81)$$

Thus under the conditions of the joint a-priori measure K , γ' is a specification and the RCFLM satisfying Dobrushin's condition uniformly in η is sufficient for γ' to be Gibbsian.

Next we present the proof of Theorem 2.9

Proof of Theorem 2.9: This Theorem is an application of Theorem 2.5. The only quantities we have to worry about are the entries of the Dobrushin interdependence matrix \bar{C} . It follows from the hypothesis of the Theorem; namely the continuity property of the interaction and the terms in the bound on $c'[\eta]$ in Corollary 4.5 that

$$\begin{aligned} & \frac{1}{2} \exp\left(\frac{1}{2} \sum_{A \supset \{i, j\}} \delta(\Phi_A)\right) L_{ij} \inf_{a_i \in S_{\eta_i}} \left(\int_{S_{\eta_i}} d^2(\sigma_i, a_i) \alpha_{\eta_i}(d\sigma_i) \right)^{\frac{1}{2}} \\ & \leq \sup_{\eta_i \in S'} \frac{\rho_{\eta_i}}{2} \exp\left(\frac{1}{2} \sum_{A \supset \{i, j\}} \delta(\Phi_A)\right) L_{ij} = \bar{C}_{ij}, \end{aligned} \quad (82)$$

where $\rho_{\eta_i} := \text{diam}(S_{\eta_i})$.

□

5 Proof of results on short-time Gibbsianness for time-evolved rotator models

Proof of Theorem 2.7: We begin the proof by establishing a uniform bound on the Dobrushin constants $c[\eta]$ for the RCFLM associated with the rotator model under site-wise independent diffusive time-evolution. As discussed in Subsection 2.4, the rotator interaction satisfies the Lipschitz-condition (17) with constants $L_{ij} = 2|J_{ij}|$ hence we can use the estimates on $c[\eta]$ given by Corollary 4.5, i.e.

$$c'[\eta] \leq \frac{1}{2} \sup_{i \in G} \sum_{j \in G} \exp\left(\frac{1}{2} \sum_{A \supset \{i, j\}} \delta(\Phi_A)\right) L_{ij} \inf_{a_i \in S} \left(\int_S d^2(\sigma_i, a_i) \alpha_{\eta_i}(d\sigma_i) \right)^{\frac{1}{2}}. \quad (83)$$

To obtain the desired bound we have to evaluate all the quantities appearing in the above estimate on $c[\eta]$. We start with the evaluation of the quantity

$$\int_S d^2(\sigma_i, a_i) \alpha_{\eta_i}(d\sigma_i) = \int_{S^{q-1}} d^2(\sigma_i, a_i) k_t(\sigma_i, \eta_i) \alpha_o(d\sigma_i). \quad (84)$$

Observe that in this set-up $S = S' = S^{q-1}$. Take $a_i = e_q = (0, \dots, 0, 1)$, the q th canonical basis element for the q -dimensional Euclidean space. Then it is elementary to see that

$$d^2(\sigma_i, a_i) = (\sigma_i)^2 + (a_i)^2 - 2\sigma_i a_i = 2(1 - \sigma_i^q),$$

where we have set $\sigma_i = (\sigma_i^1, \dots, \sigma_i^q)$. To compute the above integral we denote by Z_t^q the q -th coordinate of a diffusion on the sphere started at $Z_{t=0}^q = 1$ (the "north-pole") and denote the corresponding expectation by \mathbb{E} . Thus for any η_i we have;

$$\int \alpha_o(d\sigma_i) k_t(\sigma_i, \eta_i) d^2(\sigma_i, \eta_i) = 2(1 - \mathbb{E}Z_t^q) = 2(1 - e^{-(q-1)t}). \quad (85)$$

The first equality uses the idea that Brownian motion on the sphere is rotation invariant and consequently choosing $\eta_i = a_i$. To see the last equality use either an explicit form of the q th component of the transition kernel k_t (115) in polar coordinates and orthogonality of Legendre polynomials as in [2]. Or use that the generator of the diffusion Z_t^q given by the u -dependent parts of the Laplace-Beltrami operator on the sphere (see e.g. p. 38, eq 54 of [2]) which reads

$$(1 - u^2)\left(\frac{d}{du}\right)^2 - (q - 1)u\frac{d}{du}. \quad (86)$$

Then it follows from stochastic differential equations (SDE) theory (see e.g. chp5 of [15]) that

$$dZ_t^q = -(q - 1)Z_t^q dt + \sqrt{2(1 - (Z_t^q)^2)} dB_t, \quad (87)$$

where B_t is a one-dimensional standard Brownian motion. The solutions of this SDE satisfy the equation

$$\frac{d}{dt}\mathbb{E}Z_t^q = -(q - 1)\mathbb{E}Z_t^q.$$

Solving the above differential equation with the initial condition $Z_{t=0}^q = 1$ yields

$$\mathbb{E}Z_t^q = e^{-(q-1)t}.$$

This concludes the justification of the second equality in (85).

The last quantity we want to evaluate is $\sum_{A \supset \{i,j\}} \delta(\Phi_A)$. But with the rotator model we are considering this quantity is equals to $2|J_{ij}|$. So putting all the above together we get

$$c'[\eta] \leq \sqrt{2} \sup_{i \in G} \sum_{j \in G} e^{|J_{ij}|} |J_{ij}| \left(1 - e^{-(q-1)t}\right)^{\frac{1}{2}}. \quad (88)$$

The above estimate on $c'[\eta]$ is uniform in η . We denote by $\bar{C}(t)$ the matrix with entries

$$\bar{C}_{ij}(t) = \sqrt{2} e^{|J_{ij}|} |J_{ij}| \left(1 - e^{-(q-1)t}\right)^{\frac{1}{2}}.$$

We will in our analysis with the abuse of notation refer to this matrix as the Dobrushin interdependence matrix for the RCFLM of our current situation.

1. As we saw in the proof of Theorem 2.5, γ'_t is a specification and a sufficient condition for it to be Gibbsian is

$$\sup_{i \in G} \sum_{j \in G} \bar{C}_{ij}(t) < 1,$$

i.e. the RCFLM satisfies Dobrushin's condition uniformly in η . This concludes the proof of (1).

2. The proof follows from two-step estimation procedures. The first uses the continuity estimate on γ'_i as given by Theorem 2.5 and the second uses a telescoping argument.

As our first step we adapt the continuity estimate on γ'_i in Theorem 2.5 to the current set-up to obtain a continuity estimate for $\gamma'_{i,t}$. We only have to worry about the goodness matrix $Q(t)$ and the posterior metric d' . Here we take the entries of the goodness matrix $Q(t)$ to be the bounds on Q_{ij} given in (16), i.e.

$$\begin{aligned} Q_{ij}(t) &= 4 \exp \left(4 \sup_{i \in G} \sum_{A \ni i} \|\Phi_A\|_\infty \right) \sum_{k \in i^c} \delta_k \left(\sum_{A \supset \{i,k\}} \Phi_A \right) \bar{D}_{kj}(t) \\ &= 8 \exp \left(4 \sup_{i \in G} \sum_{j \in G} |J_{ij}| \right) \sum_{k \in i^c} |J_{ik}| \bar{D}_{kj}(t), \quad \text{with} \\ \bar{D}_{kj}(t) &= \left(\sum_{n=0}^{\infty} \bar{C}(t)^n \right)_{kj} = \left(\mathbf{1} + \sum_{n=1}^{\infty} (1 - e^{-(q-1)t})^{\frac{n}{2}} A^n \right)_{kj}, \end{aligned} \quad (89)$$

where $A_{ij} = e^{|J_{ij}|} |J_{ij}|$.

Observe further from Proposition 2.8 that the posterior metric d' has an estimate

$$d'(\eta_i, \bar{\eta}_i) \leq \sqrt{\frac{\pi}{4t}} d(\eta_i, \bar{\eta}_i),$$

where d is the Euclidean metric. Therefore putting all the above together we arrive at the following continuity estimate for $\gamma'_{i,t}$:

$$\|\gamma'_{i,t}(\cdot | \eta_{i^c}) - \gamma'_{i,t}(\cdot | \bar{\eta}_{i^c})\| \leq \sqrt{\frac{\pi}{4t}} \sum_{j \in i^c} Q_{ij}(t) d(\eta_j, \bar{\eta}_j). \quad (90)$$

The next estimation follows from a telescoping argument involving the sites in i^c . The main result in this direction that we will employ in our proof is formulated in the lemma below.

Lemma 5.1. *For each non-empty finite subset $V_1 \subset i^c$ we have the following estimate*

$$\begin{aligned} \|\gamma'_{i,t}(\cdot | \eta_{i^c}) - \gamma'_{i,t}(\cdot | \bar{\eta}_{i^c})\| &\leq \frac{1}{2} \sum_{j \in V_1} \min \left\{ \sqrt{\frac{\pi}{t}} Q_{ij}(t), e^{4 \sum_{k \in G} |J_{jk}|} - 1 \right\} d(\eta_j, \bar{\eta}_j) \\ &+ \|\gamma'_{i,t}(\cdot | \eta_{V_1^c \setminus i} \bar{\eta}_{V_1}) - \gamma'_{i,t}(\cdot | \bar{\eta}_{i^c})\|. \end{aligned} \quad (91)$$

Note from the second term in the above bound that the conditionings coincides in the chosen finite volume V_1 . We proceed by applying the Lemma 5.1 to obtain a similar bound for $\|\gamma'_{i,t}(\cdot | \eta_{V_1^c \setminus i} \bar{\eta}_{V_1}) - \gamma'_{i,t}(\cdot | \bar{\eta}_{i^c})\|$ this time for any non-empty finite subset $V_2 \subset G \setminus V_1 \cup \{i\}$. Thus we have

$$\begin{aligned} \|\gamma'_{i,t}(\cdot | \eta_{i^c}) - \gamma'_{i,t}(\cdot | \bar{\eta}_{i^c})\| &\leq \frac{1}{2} \sum_{j \in V_1 \cup V_2} \min \left\{ \sqrt{\frac{\pi}{t}} Q_{ij}(t), e^{4 \sum_{k \in G} |J_{jk}|} - 1 \right\} d(\eta_j, \bar{\eta}_j) \\ &+ \|\gamma'_{i,t}(\cdot | \eta_{(V_1 \cup V_2)^c \setminus i} \bar{\eta}_{V_1 \cup V_2}) - \gamma'_{i,t}(\cdot | \bar{\eta}_{i^c})\|. \end{aligned} \quad (92)$$

Successive application of Lemma 5.1 along such sequence of pair-wise disjoint non-empty finite subsets V_n such that $\cup_n V_n = i^c$ yields the desired result.

□

Proof of Lemma 5.1:

For any non-empty finite subset $\Lambda \subset i^c$ we let $n_\Lambda : \Lambda \rightarrow \{1, 2, \dots, |\Lambda|\}$ be a bijection between Λ and $\{1, 2, \dots, |\Lambda|\}$ and denote by $\bar{\eta}_{l \leq \eta}$ the configuration that coincides with $\bar{\eta}$ on $n_\Lambda^{-1}(\{1, \dots, l\})$ and η on $G \setminus n_\Lambda^{-1}(\{1, \dots, l\}) \cup \{i\}$. The map n_Λ orders the elements in Λ . For $G = \mathbb{Z}^2$ this map can be a spiral ordering of the sites in Λ . Recall that the joint a priori measure $K_t(d\sigma_i, d\eta_i) = k_t(\sigma_i, \eta_i)\alpha_o(d\sigma_i)\alpha_o(d\eta_i)$ where as before $\alpha_o(\cdot) = \int K_t(\cdot, d\sigma_i)$. In this way it follows from (58) that we can write the single-site part of γ'_t as

$$\begin{aligned} \gamma'_{i,t}(d\eta_i|\eta_{i^c}) &= f(\eta_i|\eta_{i^c})\alpha_o(d\eta_i), \quad \text{where} \\ f(\eta_i|\eta_{i^c}) &= \frac{\int_{S^{i^c}} \mu_{i^c}[\eta_{i^c}](d\tilde{\sigma}_{i^c}) \int_S \exp\left(-H_i(\sigma_i, \tilde{\sigma}_{i^c})\right) k_t(\sigma_i, \eta_i)\alpha_o(d\sigma_i)}{\int_{S^{i^c}} \mu_{i^c}[\eta_{i^c}](d\tilde{\sigma}_{i^c}) \int_S \exp\left(-H_i(\sigma_i, \tilde{\sigma}_{i^c})\right) \alpha_o(d\sigma_i)}. \end{aligned} \quad (93)$$

With the order on Λ we can now write for any pair of conditionings $\eta, \bar{\eta} \in \Omega' = (S')^G$

$$\begin{aligned} f(\eta_i|\eta_{i^c}) - f(\eta_i|\bar{\eta}_{i^c}) &= \sum_{l=1}^{|\Lambda|+1} \nabla_l f(\eta_i|\eta_{i^c}, \bar{\eta}_{i^c}) \quad \text{with} \\ \nabla_l f(\eta_i|\eta_{i^c}, \bar{\eta}_{i^c}) &= \begin{cases} f(\eta_i|\bar{\eta}_{l-1 \leq \eta}) - f(\eta_i|\bar{\eta}_{l \leq \eta}) & \text{if } 1 \leq l \leq |\Lambda|; \\ f(\eta_i|\bar{\eta}_{|\Lambda| \leq \eta}) - f(\eta_i|\bar{\eta}_{i^c}) & \text{if } l = |\Lambda| + 1, \end{cases} \end{aligned} \quad (94)$$

where we assume $\{1, \dots, l-1\} = \emptyset$ for $l = 1$. In this spirit it follows from the triangle inequality that

$$\begin{aligned} \|\gamma'_{i,t}(\cdot|\eta_{i^c}) - \gamma'_{i,t}(\cdot|\bar{\eta}_{i^c})\| &= \int \alpha_o(d\eta_i) \left| \sum_{l=1}^{|\Lambda|+1} \nabla_l f(\eta_i|\eta_{i^c}, \bar{\eta}_{i^c}) \right| \\ &\leq \sum_{l=1}^{|\Lambda|} \int_{S'} \alpha_o(d\eta_i) |\nabla_l f(\eta_i|\eta_{i^c}, \bar{\eta}_{i^c})| + \|\gamma'_{i,t}(\cdot|\bar{\eta}_\Lambda \eta_{G \setminus (\{i\} \cup \Lambda)}) - \gamma'_{i,t}(\cdot|\eta_{i^c})\|. \end{aligned} \quad (95)$$

To get the desired bound for the first term in the above inequality we use two estimation procedures which provide bounds for the terms in the sum that are multiples of $d(\eta_j, \bar{\eta}_j)$.

First of all, note that for any $1 \leq l \leq |\Lambda|$ the conditionings in the definition of $\nabla_l f(\cdot|\eta_{i^c}, \bar{\eta}_{i^c})$ coincide except at the site $j = n_\Lambda^{-1}(l)$. Thus for any $1 \leq l \leq |\Lambda|$ it follows from (90) that

$$\|\gamma'_{i,t}(\cdot|\bar{\eta}_{l-1 \leq \eta}) - \gamma'_{i,t}(\cdot|\bar{\eta}_{l \leq \eta})\| = \int_{S'} \alpha_o(d\eta_i) |\nabla_l f(\eta_i|\eta_{i^c}, \bar{\eta}_{i^c})| \leq \sqrt{\frac{\pi}{4t}} Q_{ij}(t) d(\eta_j, \bar{\eta}_j), \quad (96)$$

since $\eta_k = \bar{\eta}_k$ for all $k \in \{i, j\}^c$.

Next we apply the following estimation technique to obtain a second bound on $\|\gamma'_{i,t}(\cdot|\bar{\eta}_{l-1 \leq \eta}) - \gamma'_{i,t}(\cdot|\bar{\eta}_{l \leq \eta})\|$ for $1 \leq l \leq |\Lambda|$. First we set $j = n_\Lambda^{-1}(l)$ and note that

$$\frac{f(\eta_i|\bar{\eta}_{l-1 \leq \eta})}{f(\eta_i|\bar{\eta}_{l \leq \eta})} = \frac{f(\eta_j|\eta_i \bar{\eta}_{l-1 \leq \eta_{l>}})}{f(\bar{\eta}_j|\eta_i \bar{\eta}_{l-1 \leq \eta_{l>}})} \times \frac{\int_{S'} f(\eta_i, \bar{\eta}_j|\bar{\eta}_{l-1 \leq \eta_{l>}})\alpha_o(d\eta_i)}{\int_{S'} f(\eta_i, \eta_j|\bar{\eta}_{l-1 \leq \eta_{l>}})\alpha_o(d\eta_i)}, \quad (97)$$

where $\bar{\eta}_{l-1 \leq \eta_l >}$ is the configuration that coincides with $\bar{\eta}$ on $n_\Lambda^{-1}(\{1, \dots, l-1\})$ and η on $G \setminus (n_\Lambda^{-1}(\{1, \dots, l-1\}) \cup \{i, j\})$ and $f(\eta_i, \eta_j | \bar{\eta}_{l-1 \leq \eta_l >})$ is given by (93) if we appropriately replace i in (93) with $\{i, j\}$. The validity of (97) follows for the following considerations;

$$f(\eta_i, \eta_j | \dots) = f(\eta_i | \eta_j \dots) \int \alpha_o(d\eta_i) f(\eta_i, \eta_j | \dots) = f(\eta_j | \eta_i \dots) \int \alpha_o(d\eta_j) f(\eta_i, \eta_j | \dots)$$

$$\text{thus } f(\eta_i | \eta_j \dots) = f(\eta_j | \eta_i \dots) \frac{\int \alpha_o(d\eta_j) f(\eta_i, \eta_j | \dots)}{\int \alpha_o(d\eta_i) f(\eta_i, \eta_j | \dots)} \quad \text{and similarly}$$

$$f(\eta_i | \bar{\eta}_j \dots) = f(\bar{\eta}_j | \eta_i \dots) \frac{\int \alpha_o(d\eta_j) f(\eta_i, \eta_j | \dots)}{\int \alpha_o(d\eta_i) f(\eta_i, \bar{\eta}_j | \dots)}.$$

Therefore by setting

$$h_2(\sigma_{j^c}, \eta_j) = \int_S \exp(-H_j(\sigma_j \sigma_{j^c})) k_t(d\sigma_j, \eta_j) \alpha_o(d\sigma_i)$$

we obtain

$$\frac{f(\eta_j | \eta_i \bar{\eta}_{l-1 \leq \eta_l >})}{f(\bar{\eta}_j | \eta_i \bar{\eta}_{l-1 \leq \eta_l >})} = \frac{\mu_{j^c}[\eta_i \bar{\eta}_{l-1 \leq \eta_l >}] [h_2(\sigma_{j^c}, \eta_j)]}{\mu_{j^c}[\eta_i \bar{\eta}_{l-1 \leq \eta_l >}] [h_2(\sigma_{j^c}, \bar{\eta}_j)]}. \quad (98)$$

Let R be a rotation such that $R\bar{\eta}_j = \eta_j$ and set $\sigma'_j = R\sigma_j$. Then it follows from

$$|H_j(\sigma_j \sigma_{j^c}) - H_j(\sigma'_j \sigma_{j^c})| \leq \left(\sum_{k \in G} |J_{jk}| \right) d(\eta_j, \bar{\eta}_j)$$

that

$$\begin{aligned} h_2(\sigma_{j^c}, \eta_j) &= \\ &\int_S \left\{ \int_S \exp \left(- \left(H_j(\sigma_j \sigma_{j^c}) - H_j(\sigma'_j \sigma_{j^c}) \right) - H_j(\sigma'_j \sigma_{j^c}) \right) K_t(d\sigma'_j | \eta_j) \right\} K_t(d\sigma_j | \eta_j) \\ &\leq \exp \left(c_j d(\eta_j, \bar{\eta}_j) \right) \int_S \exp \left(- H_j(\sigma'_j \sigma_{j^c}) \right) K_t(d\sigma'_j | \eta_j) \end{aligned} \quad (99)$$

and similarly

$$h_2(\sigma_{j^c}, \bar{\eta}_j) \leq \exp \left(c_j d(\eta_j, \bar{\eta}_j) \right) \int_S \exp \left(- H_j(\sigma_j \sigma_{j^c}) \right) K_t(d\sigma_j | \eta_j)$$

where $c_j = \sum_{k \in G} |J_{jk}|$. It follows from (98) and the rotation invariance of K_t that

$$\begin{aligned} \frac{f(\eta_j | \eta_i \bar{\eta}_{l-1 \leq \eta_l >})}{f(\bar{\eta}_j | \eta_i \bar{\eta}_{l-1 \leq \eta_l >})} &\leq \frac{e^{c_j d(\eta_j, \bar{\eta}_j)} \mu_{j^c}[\eta_i \bar{\eta}_{l-1 \leq \eta_l >}] \left[\int_S \exp \left(- H_j(\sigma'_j \sigma_{j^c}) \right) K_t(d\sigma'_j | \eta_j) \right]}{\mu_{j^c}[\eta_i \bar{\eta}_{l-1 \leq \eta_l >}] \left[\int_S \exp \left(- H_j(\sigma'_j \sigma_{j^c}) \right) k_t(d\sigma'_j, \eta_j) \alpha_o(d\sigma_i) \right]} \\ &= e^{c_j d(\eta_j, \bar{\eta}_j)}. \end{aligned} \quad (100)$$

The above estimate follows by applying the rotation R to the $\bar{\eta}_j$ in the r.h.s. of (98). Furthermore, it is not hard to deduce that

$$\frac{\int_{S'} f(\eta_i, \bar{\eta}_j | \bar{\eta}_{l-1 \leq \eta_l >}) \alpha_o(d\eta_i)}{\int_{S'} f(\eta_i, \eta_j | \bar{\eta}_{l-1 \leq \eta_l >}) \alpha_o(d\eta_i)} \leq \sup_{\eta_i} \frac{f(\bar{\eta}_j | \eta_i \bar{\eta}_{l-1 \leq \eta_l >})}{f(\eta_j | \eta_i \bar{\eta}_{l-1 \leq \eta_l >})} \leq e^{c_j d(\eta_j, \bar{\eta}_j)}. \quad (101)$$

Therefore it follows from (97) that

$$\frac{f(\eta_i|\bar{\eta}_{l-1}\leq\eta)}{f(\eta_i|\bar{\eta}_l\leq\eta)} \leq e^{2c_j d(\eta_j, \bar{\eta}_j)}. \quad (102)$$

Hence for any $1 \leq l \leq |\Lambda|$ we have

$$\begin{aligned} \int_S \alpha_o(d\eta_i) \left| \nabla_l f(\eta_i|\eta_i^c, \bar{\eta}_i^c) \right| &= \int_S \alpha_o(d\eta_i) \left| \left(\frac{f(\eta_i|\bar{\eta}_{l-1}\leq\eta)}{f(\eta_i|\bar{\eta}_l\leq\eta)} - 1 \right) f(\eta_i|\bar{\eta}_l\leq\eta) \right| \\ &\leq e^{2c_j d(\eta_j, \bar{\eta}_j)} - 1 \leq \frac{e^{4c_j} - 1}{2} d(\eta_j, \bar{\eta}_j). \end{aligned} \quad (103)$$

Comparing (96) and (103) it is clearly seen for any $1 \leq l \leq |\Lambda|$ with $j = n_\Lambda^{-1}(l)$ that

$$\left\| \gamma'_{i,t}(\cdot|\bar{\eta}_{l-1}\leq\eta) - \gamma'_{i,t}(\cdot|\bar{\eta}_l\leq\eta) \right\| \leq \frac{1}{2} \min \left\{ \sqrt{\frac{\pi}{t}} Q_{ij}(t), e^{4\sum_{k \in G} |J_{jk}|} - 1 \right\} d(\eta_j, \bar{\eta}_j), \quad (104)$$

which proves the lemma. \square

Lemma 5.1 has an extension for interactions for which $H_j(\cdot\sigma_{j^c})$ is not Lipschitz continuous. In this set-up we have for any non-empty finite subset $V \subset i^c$

$$\left\| \gamma'_{i,t}(\cdot|\eta_i^c) - \gamma'_{i,t}(\cdot|\bar{\eta}_i^c) \right\| \leq \sum_{j \in V} \left(e^{4\delta_j \left(\sum_{A \ni j} \Phi_A \right)} - 1 \right) + \left\| \gamma'_{i,t}(\cdot|\eta_{V^c \setminus i} \bar{\eta}_V) - \gamma'_{i,t}(\cdot|\bar{\eta}_i^c) \right\|. \quad (105)$$

To obtain the desired bound on the posterior metric as given in Proposition 2.8 we need to solve the diffusion equation on the sphere S^{q-1} generated by the Laplace-Beltrami operator. This bound is further used in Theorem 2.7 to replace the posterior metric d' in the goodness for the Gibbs specification of the corresponding transformed system (as provided by Theorem 2.5) with the Euclidean metric d . We employ stochastic differential equation (SDE) technique to arrive at the bound of interest. It turns out that we only need the q th component of the diffusion to get the desired bound. We employ coupling of reflected diffusions on the sphere with the equator as the mirror as our main tool. To obtain the desired bound we make use of the coupling time which is the first time the q th component of the diffusion visits zero. This necessitates focusing attention on only the q th component. We start with the following lemma.

Lemma 5.2. 1. Denote by Z_t the q th-component of the diffusion on the sphere S^{q-1} for $q \geq 2$, started at a value $y := \sin \varphi_0$ with $\varphi_0 \in (0, \frac{\pi}{2})$. Then there is a coupling of Z_t to a Brownian motion on the line, B_t , such that the first passage time of Z_t at zero, denoted by $T_0(Z^q)$, is dominated from above by the first passage time $T_0(\varphi_0 + \sqrt{2}B_t)$ of $\varphi_0 + \sqrt{2}B_t$.

2. Consequently, independently of the dimension $q - 1$, there is the estimate

$$\frac{1}{2} F_{q,t}(2y) := \mathbb{P}^y(T_0(Z^q) > t) \leq \mathbb{P}^{\varphi_0}(T_0(\varphi_0 + \sqrt{2}B_t) > t) \leq 2\mathbb{P}\left(0 \leq G \leq \frac{\varphi_0}{\sqrt{2t}}\right) \quad (106)$$

where G is a standard normal variable.

Proof: Consider the case $q \geq 3$ first. Recall from (86) and (87) that the SDE for the q -th component of the diffusion on the sphere reads,

$$dZ_t^q = -(q-1)Z_t^q dt + \sqrt{2(1-(Z_t^q)^2)} dB_t. \quad (107)$$

Consider the transformation

$$Z_t^q = \sin(\bar{\varphi}_t) \quad (108)$$

to an unknown function $\bar{\varphi}_t$ describing the elevation above the equator. We apply this transformation only for $0 \leq Z_t^q < 1$, and so there is a one-to-one map to $0 \leq \bar{\varphi}_t < \frac{\pi}{2}$. In this range the SDE is equivalent to

$$d\bar{\varphi}_t = -(q-2) \tan \bar{\varphi}_t dt + \sqrt{2} dB_t. \quad (109)$$

Indeed, for $q \geq 3$ the diffusion $\bar{\varphi}_t$ does not leave the interval $(-\frac{\pi}{2}, \frac{\pi}{2})$, meaning that, with probability one the north-pole is never reached by Z_t^q . Integrating from zero to t we obtain from (109)

$$\bar{\varphi}_t = -(q-2) \int_0^t \tan \bar{\varphi}_s ds + \sqrt{2} B_t + \varphi_0. \quad (110)$$

From this equality we see that as long as $\bar{\varphi}_s \geq 0$ for all $s \in [0, t]$ we have the bound $\bar{\varphi}_t \leq \sqrt{2} B_t + \varphi_0$. This shows that the first passage time of $\bar{\varphi}_t$ is not bigger than that of $\sqrt{2} B_t + \varphi_0$. The proof of the inequality follows from bounding $\mathbb{P}(T_0(Z^q) \geq t)$ from above by the first passage time of the Brownian motion on a line, $\mathbb{P}(T_0(\sqrt{2} B + \varphi_0) \geq t)$. The latter can be computed exactly by the reflection principle applied to standard Brownian motion, as it is well-known (see e.g. [15; 16]). (We will use the reflection principle also in the proof of Lemma 5.5, applied to the diffusion on the sphere.) This gives rise to the estimate on the r.h.s.

That the inequality holds also in the case $q = 2$ (and is a strict inequality then) can be seen directly without making reference to the SDE. We note that the paths of a diffusion on the circle are given by Brownian motions on the angular variable, i.e. $\bar{\varphi}_t = \sqrt{2} B_t + \varphi_0$. Then $\bar{\varphi}_t = 0$ implies that $Z_t^2 = \sin(\bar{\varphi}_t) = 0$, but the converse is not true.

It is interesting to realize that this construction provides a coupling such that $Z_t^q \leq \sqrt{2} B_t + \varphi_0$, for $q \geq 3$, $Z_t^2 \leq \sqrt{2} B_t + \varphi_0$ but *not* $Z_t^q \leq Z_t^2$. The latter relation is guaranteed to hold only as long as $0 \leq \sqrt{2} B_t + \varphi_0 \leq \frac{\pi}{2}$.

□

Proof of the Proposition 2.8: First of all we know from coupling theory (see eq.1 of [13]) and arguments used in the proof of Lemma 5.5 that

$$d'(\eta_j, \bar{\eta}_j) \leq 2\mathbb{P}^{\frac{x}{2}}(T_0 > t) = F_{q,t}(x),$$

where $x = d(\eta_j, \bar{\eta}_j)$ is the Euclidean distance between η_j and $\bar{\eta}_j$. It follows from Lemma 5.2 that, for any $q \geq 2$,

$$F_{q,t}(x) = 2\mathbb{P}^{\frac{q}{2}}(T_0 > t) \leq 4\mathbb{P}\left(0 \leq G \leq \frac{\arcsin \frac{x}{2}}{\sqrt{2t}}\right). \quad (111)$$

Using $\mathbb{P}\left(0 \leq G \leq u\right) \leq \frac{u}{\sqrt{2\pi}}$ by concavity and $\arcsin y \leq \frac{\pi}{2}y$ for $0 \leq y \leq 1$ we obtain $F_{q,t}(x) \leq \frac{\sqrt{\pi}x}{2\sqrt{t}}$. Note that in both of the last estimates the constants were sharp.

□

Appendix A: Estimates on the Posterior metric on the spheres

We saw in the proof of Proposition 2.8 that the posterior metric d' is dominated by the function $F_{q,t}$. This function was defined in terms of first passage time to level zero of the q th component of the diffusion on the sphere S^{q-1} . We give an analytical representation of this functions in terms of eigenfunctions of the Laplace-Beltrami operator [2] on the sphere.

Proposition 5.3. *Recall the situation of Proposition 2.8. In general dimensions $q \geq 2$ the function $F_{q,t}$ has the representation*

$$F_{q,t}(x) = \sum_{m=0}^{\infty} a_{q,m}(t) P_{2m+1}\left(q, \frac{x}{2}\right) \text{ with} \quad (112)$$

$$a_{q,m}(t) = e^{-(2m+1)(2m+q-1)t} \frac{(-1)^m 4N(q, m) \Gamma\left(\frac{q}{2}\right)}{\sqrt{\pi} \Gamma\left(\frac{q-1}{2}\right)} \prod_{i=0}^m \left(\frac{2i-1}{q+2i-1}\right)$$

in terms of Legendre polynomials $P_n(q, s)$ of degree n in dimension q (see Definition 5.4) and $N(q, m)$ is also the dimension of the space of spherical harmonics of degree n in dimension q (see (115)).

Before we prove Proposition 5.3 let us fix the following notations starting with the definition of q -dimensional Legendre polynomials (see [2]).

Definition 5.4. *The Legendre polynomial $P_n(q, \cdot)$ of degree n in dimension $q \geq 2$ is given by the Rodrigues formula*

$$P_n(q, s) := \frac{(-1)^n \Gamma\left(\frac{q-1}{2}\right)}{2^n \Gamma\left(n + \frac{q-1}{2}\right)} (1-s^2)^{\frac{3-q}{2}} \left(\frac{d}{ds}\right)^n (1-s^2)^{\frac{q-3}{2}+n}, \quad (113)$$

where $-1 \leq s \leq 1$.

These Legendre polynomials are known (see [2] for example) to be orthogonal and satisfy the second order differential equations

$$\left[(1-s^2) \frac{d^2}{ds^2} - (q-1)s \frac{d}{ds} + n(n+q-2) \right] P_n(q, s) = 0. \quad (114)$$

The last equation indicates that the Legendre polynomials are eigenfunctions for the eigenvalue problem for the q th component of the Laplace-Beltrami operator on the sphere S^{q-1} . Using the above fact and the separation of variables method we can write the transition (heat) kernel k_t of the q th component Z_t^q of the diffusion on the sphere S^{q-1} as

$$k_t(s, u) := \frac{\Gamma(\frac{q}{2})}{\sqrt{(\pi)\Gamma(\frac{q-1}{2})}} \sum_{n=0}^{\infty} e^{-n(n+q-2)t} N(q, n) P_n(q, s) P_n(q, u), \quad \text{where} \quad (115)$$

$$N(q, n) := \begin{cases} \frac{(2n+q-2)\Gamma(n+q-2)}{\Gamma(n+1)\Gamma(q-1)} & \text{if } n \geq 1; \\ 1 & \text{if } n = 0 \end{cases}$$

is the dimension of spherical harmonics of degree n in dimension q . Further we have set $Z_0^q = s$ and $Z_t^q = u$, and we have also chosen the constant $\frac{\Gamma(\frac{q}{2})}{\sqrt{(\pi)\Gamma(\frac{q-1}{2})}}$ so that for any initial s the integral of $k_t(s, u)$ with respect to the invariant measure $(1-u^2)^{\frac{q-3}{2}} du$ (which is the q -coordinate projection of the invariant surface measure on the sphere) over the interval $[-1,1]$ is equal to one. We collect the following two lemmas from which the proof of Proposition 5.3 will follow.

Lemma 5.5. *For the diffusion on a sphere there is an estimate of the posterior-metric $d'(\eta_j, \bar{\eta}_j)$ at fixed t in terms of $d(\eta_j, \bar{\eta}_j)$, the induced metric on the sphere S^{q-1} obtained by embedding the sphere into the Euclidean space, given by*

$$d'(\eta_j, \bar{\eta}_j) \leq F_{q,t}(d(\eta_j, \bar{\eta}_j)) \quad (116)$$

with the function

$$F_{q,t}(x) = 2\left(1 - 2P^{\frac{x}{2}}(Z_t^q \leq 0)\right) = \frac{-4\Gamma(\frac{q}{2})}{\sqrt{\pi}\Gamma(\frac{q-1}{2})} \sum_{n=1,3,5,\dots} e^{-n(n+q-2)t} N(q, n) P_n\left(q, \frac{x}{2}\right) \int_{-1}^0 P_n(q, s) (1-s^2)^{\frac{q-3}{2}} ds \quad (117)$$

Proof:

The idea of the proof is to construct a coupling of two diffusions on the sphere starting at the points η_j and $\bar{\eta}_j$. By rotation invariance of such diffusions we assume that η_j and $\bar{\eta}_j$ are mirror images of each other under reflection at the equatorial plane. Then we construct a coupling by reflection [13] of the path started at η_j with the equator as the mirror line, up to the time when the diffusion hits the equator. After that the two diffusions move on together. In this way the coupling time for the two diffusions is the same as the first time $Z_t^q = 0$ (the first passage time T_0 to level 0 given by $T_0 := \inf\{t \geq 0, Z_t = 0\}$) for either $Z_0^q = z$ or $Z_0^q = -z$ where $z = \varepsilon_q \cdot \eta_j$ (here $\varepsilon_1, \dots, \varepsilon_q$ constitute the canonical orthonormal basis for \mathbb{R}^q and " \cdot " is the usual scalar product). We know from coupling theory [13] that

$$d'(\eta_j, \bar{\eta}_j) \leq 2\mathbb{P}^{\frac{x}{2}}(T_0 > t) = F_{q,t}(x),$$

where $x = d(\eta_j, \bar{\eta}_j)$ is the Euclidean distance between η_j and $\bar{\eta}_j$. Further it follows from the reflection principle of Désiré André ([15],pp.79-81 and [16],p.293) that

$$\mathbb{P}^{\frac{x}{2}}(T_0 \leq t) = 2\mathbb{P}^{\frac{x}{2}}(Z_t^q \leq 0) = 2 \int_{-1}^0 k_t\left(\frac{x}{2}, s\right) (1-s^2)^{\frac{q-3}{2}} ds.$$

The heuristic argument for the first equality in the above equation is as follows; the probability that the first passage time T_0 (to a level 0 for a 1-dimensional diffusion starting at some initial point $y > 0$) is less or equal to t is the sum of the probabilities of the events that $T_0 \leq t$ and $Z_t^q < 0$, and $T_0 \leq t$ and $Z_t^q > 0$. The probability for the first event is the same as the probability for the event that the 1-dimensional diffusion Z_t^q starting at y is below the level 0. For the probability of the second event observe that after the diffusion reached level 0, it has equal probability to reach level $-c$ below 0 or level c above 0 since the diffusion in our set-up is symmetric about 0. Hence the probability of the second event is the same as the first due to the symmetry of Z_t^q about 0. From here follows the first equality of the expression for $F_{q,t}$ in the lemma.

It follows from the orthogonality property of the Legendre polynomials that for each positive even integer n the integral

$$\int_{-1}^0 P_n(q, s)(1 - s^2)^{\frac{q-3}{2}} ds = \frac{1}{2} \int_{-1}^1 P_n(q, s)P_0(q, s)(1 - s^2)^{\frac{q-3}{2}} ds = 0$$

(since $P_0(q, s) = 1$) for all $q \geq 2$. Therefore the rest of the proof follows from (115) and the value of the integral

$$\int_{-1}^1 P_0(q, s)^2(1 - s^2)^{\frac{q-3}{2}} ds = \frac{\sqrt{\pi}\Gamma\left(\frac{q-1}{2}\right)}{\Gamma\left(\frac{q}{2}\right)}.$$

□

We have seen from the above proof that for positive even integers n the integral (over $[-1,0]$ and w.r.t to the invariant measure $(1 - s^2)^{\frac{q-3}{2}} ds$) of the Legendre polynomial of degree n is always equal to zero, as long as the dimension $q \geq 2$. The integral for the corresponding odd degree case can also be computed explicitly and we formulate this explicit value of the integral as our next lemma.

Lemma 5.6. *For any odd integer $2m+1$ ($m=0,1,2,\dots$) the integral of the Legendre polynomials $P_{2m+1}(q, \cdot)$ over the interval $[-1,0]$ is given by*

$$\int_{-1}^0 P_{2m+1}(q, s)(1 - s^2)^{\frac{q-3}{2}} ds = (-1)^m \prod_{i=0}^m \left(\frac{2i-1}{q+2i-1} \right). \quad (118)$$

Proof: We obtain from definition of $P_{2m+1}(q, s)$ in Definition 5.4 that the integral

$$\begin{aligned} & \int_{-1}^0 P_{2m+1}(q, s)(1 - s^2)^{\frac{q-3}{2}} ds \\ &= \frac{-1}{2^{2m+1} \prod_{i=0}^{2m} \left(2m + \frac{q-1}{2} - i\right)} \left(\frac{d}{ds}\right)^{2m} \left(1 - s^2\right)^{2m + \frac{q-1}{2}} \Big|_{s=-1}^0. \end{aligned} \quad (119)$$

Note that for each m the above differentiation(s) will always involve terms which are multiples of $(1 - s^2)$. This implies that evaluating the above expression at $s = -1$ will always yield zero.

However, it follows from Binomial expansion of $(1 - s^2)^r$ (where $r = 2m + \frac{q-1}{2}$) that

$$\begin{aligned} & \frac{-1}{2^{2m+1} \prod_{i=0}^{2m} (2m + \frac{q-1}{2} - i)} \left(\frac{d}{ds} \right)^{2m} (1 - s^2)^{2m + \frac{q-1}{2}} \Big|_{s=0} \\ &= \frac{(-1)^{m+1} (2m)! r (r-1) \cdots (r - (m-1))}{m! 2^{2m+1} \prod_{i=0}^{2m} (2m + \frac{q-1}{2} - i)}. \end{aligned} \tag{120}$$

The rest of the proof follows from the observations that $(2m)! = 2^m m! \prod_{i=1}^m (2i - 1)$ and

$$\frac{r(r-1) \cdots (r - (m-1))}{\prod_{i=0}^{2m} (2m + \frac{q-1}{2} - i)} = \frac{2^{m+1}}{\prod_{i=0}^m (2i + q - 1)}.$$

□

Proof of Proposition 5.3: The proof follows from Lemma 5.5 and 5.6.
