37. *Proposed by M.J. Evans, Western Illinois University and C.E. Weil, Michigan State University.*

Call a subset E of the real line \mathbb{R} symmetric if for each $x \in \mathbb{R}$, there is a positive number δ_x such that for all $0 < h < \delta_x$, $x+h \in E$ if and only if $x-h \in E$. (That is, E is symmetric if its characteristic function is a symmetric function in the sense of M. Foran, Real Analysis Exchange, vol. 1 no. 1, p. 38.) Must such a set E be Lebesgue measurable?
