# The Loewner equation for multiple slits, multiply connected domains and branch points 

Christoph Böhm and Sebastian Schleißinger

#### Abstract

Let $\mathbb{D} \subset \mathbb{C}$ be the unit disk and let $\gamma_{1}, \gamma_{2}:[0, T] \rightarrow \overline{\mathbb{D}} \backslash\{0\}$ be parametrizations of two slits $\Gamma_{1}:=\gamma(0, T], \Gamma_{2}:=\gamma_{2}(0, T]$ such that $\Gamma_{1}$ and $\Gamma_{2}$ are disjoint.

Let $g_{t}$ be the unique normalized conformal mapping from $\mathbb{D} \backslash\left(\gamma_{1}[0, t] \cup \gamma_{2}[0, t]\right)$ onto $\mathbb{D}$ with $g_{t}(0)=0, g_{t}^{\prime}(0)>0$. Furthermore, for $k=1,2$, denote by $h_{k ; t}$ the unique normalized conformal mapping from $\mathbb{D} \backslash \gamma_{k}[0, t]$ onto $\mathbb{D}$ with $h_{k ; t}(0)=0, h_{k ; t}^{\prime}(0)>0$.

Loewner's famous theorem (1923) can be stated in the following way: The function $t \mapsto h_{k ; t}$ is differentiable at $t_{0}$ if and only if $t \mapsto \log \left(h_{k ; t}^{\prime}(0)\right)$ is differentiable at $t_{0}$.

In this paper we compare the differentiability of $t \mapsto h_{k ; t}$ with that of $t \mapsto g_{t}$. We show that the situation is more complicated in the case $t_{0}=0$ with $\gamma_{1}(0)=\gamma_{2}(0)$.

Furthermore, we also look at this problem in the case of a multiply connected domain with its corresponding Komatu-Loewner equation.

## 1. Introduction and results

### 1.1. The main results

## The simply connected case

By $\mathbb{D}:=\{z \in \mathbb{C}| | z \mid<1\}$ we denote the unit disk.
Let $\gamma:[0, T] \rightarrow \overline{\mathbb{D}}$ be a simple curve (i.e. $\gamma$ is continuous and injective) with $\Gamma:=\gamma(0, T] \subset \mathbb{D} \backslash\{0\}$ and $\gamma(0) \in \partial \mathbb{D}$. In the following such a set $\Gamma$ will be called slit.

For every $t \in[0, T]$, the domain $\Omega_{t}:=\mathbb{D} \backslash \gamma[0, t]$ is simply connected and it can be mapped onto $\mathbb{D}$ by a conformal map $g_{t}: \Omega_{t} \rightarrow \mathbb{D}$.

This mapping is unique if we require the normalization $g_{t}(0)=0, g_{t}^{\prime}(0)>0$. The function $g_{t}^{\prime}(0)$ is increasing and $g_{t}^{\prime}(0) \geq 1$ for all $t$ as a consequence of the Schwarz lemma. The logarithmic mapping radius is defined as $\operatorname{lmr}\left(g_{t}\right):=\log \left(g_{t}^{\prime}(0)\right)$.

The second author was partially supported by the ERC grant "HEVO-Holomorphic Evolution Equations" no. 277691.

In his much celebrated paper from 1923 [10], Loewner considered the question whether the function $t \mapsto g_{t}$ could be differentiable, even though there are no smoothness assumptions on $\Gamma$. Loewner's famous theorem can be stated in the following way:

The differentiability of $t \mapsto \operatorname{lmr}\left(g_{t}\right)$ is equivalent to the differentiability of the function $t \mapsto g_{t}$, more precisely the following statement holds; see, e.g., Theorem 2 in [2].

Theorem A. The function $c(t):=\operatorname{lmr}\left(g_{t}\right)$ is differentiable at $t=t_{0}$ if and only if the family $\left\{g_{t}\right\}_{t \in[0, T]}$ is differentiable at $t=t_{0}$, i.e. for every $z \in \mathbb{D} \backslash \Gamma$, the function $t \mapsto g_{t}(z)$ is differentiable at $t=t_{0}$. In this case, $g_{t}(z)$ satisfies the following differential equation:

$$
\begin{equation*}
\dot{g}_{t_{0}}(z)=\dot{c}\left(t_{0}\right) \cdot g_{t_{0}}(z) \cdot \frac{\xi\left(t_{0}\right)+g_{t_{0}}(z)}{\xi\left(t_{0}\right)-g_{t_{0}}(z)}, \tag{1}
\end{equation*}
$$

where $\xi\left(t_{0}\right)=\lim _{z \rightarrow \gamma\left(t_{0}\right)} g_{t_{0}}(z)$.
In the following, we will call $\gamma$ a $\mathbb{D}$-Loewner parametrization for $\Gamma$ at $t_{0}$, if the two equivalent conditions in Theorem A hold.

Remark 1.1. Usually, the parametrization of $\Gamma$ is chosen in such a way that $\operatorname{lmr}\left(g_{t}\right)=t$. In this case, the mappings $\left\{g_{t}\right\}$ are (continuously) differentiable for all $t \in[0, T]$. Thus, an arbitrary slit $\Gamma$ can be described by a differential equation for the family $\left\{g_{t}\right\}$. This celebrated idea of Loewner turned out to be quite useful for the theory of univalent mappings and its most prominent application nowadays is the stochastic Loewner evolution invented by Schramm in 2000.

Now let $\gamma_{1}, \gamma_{2}:[0, T] \rightarrow \overline{\mathbb{D}} \backslash\{0\}$ be parametrizations of two slits $\Gamma_{1}:=\gamma_{1}(0, T]$, $\Gamma_{2}:=\gamma_{2}(0, T]$ such that $\Gamma_{1}$ and $\Gamma_{2}$ are disjoint.

For a fixed time $t_{0}$ we will distinguish between two cases:
Either $\gamma_{1}\left(t_{0}\right) \neq \gamma\left(t_{0}\right)$ ("disjoint case") or $\gamma_{1}\left(t_{0}\right)=\gamma_{2}\left(t_{0}\right)$ ("branch point case"), which is only possible for $t_{0}=0$.

Again, we can define $g_{t}$ to be the unique normalized conformal mapping from $\Omega_{t}:=\mathbb{D} \backslash\left(\gamma_{1}[0, t] \cup \gamma_{2}[0, t]\right)$ onto $\mathbb{D}$ with $g_{t}(0)=0, g_{t}^{\prime}(0)>0$.

We are interested in the question, under which conditions the family $\left\{g_{t}\right\}_{t \in[0, T]}$ is differentiable at a point $t_{0} \in[0, T]$.

Again, a necessary condition is that $c(t):=\operatorname{lmr}\left(g_{t}\right):=\log \left(g_{t}^{\prime}(0)\right)$ is differentiable at $t=t_{0}$. However, this condition is not sufficient anymore, see Example 2.5.

On the other hand, the two statements are equivalent in the branch point case; see Theorem 1.7.

Figure 1. A slit approaching $\partial \mathbb{D}$ in $\alpha$-direction.

In the disjoint case, differentiability of $t \mapsto g_{t}$ is guaranteed if both slits are $\mathbb{D}$-Loewner parametrized. More precisely, the following equivalence holds.

Theorem 1.2. Suppose that $t_{0} \in[0, T]$ such that $\gamma_{1}\left(t_{0}\right) \neq \gamma_{2}\left(t_{0}\right)$. Then the following two conditions are equivalent:

1. For $j=1,2, \gamma_{j}$ is a $\mathbb{D}$-Loewner parametrization for $\Gamma_{j}$ at $t_{0}$.
2. The function $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Omega_{t_{0}}$.

For $j=1,2$, let $h_{j ; t}$ be the unique conformal mapping from $\mathbb{D} \backslash \gamma_{j}[0, t]$ onto $\mathbb{D}$ with $h_{j ; t}(0)=0, h_{j ; t}^{\prime}(0)>0$ and let $c_{j}(t):=\operatorname{lmr}\left(h_{j ; t}\right)=\log \left(h_{j ; t}^{\prime}(0)\right)$. We will also derive a relation between $\dot{c}$ and $\dot{c}_{j}$. Here we note the simplest case $t_{0}=0$ :

If the two equivalent statements in Theorem 1.2 hold for $t_{0}=0$, then $c(t)$ is differentiable at $t=0$ with

$$
\begin{equation*}
\dot{c}(0)=\dot{c}_{1}(0)+\dot{c}_{2}(0) . \tag{2}
\end{equation*}
$$

A general relation between $\dot{c}$ and $\dot{c}_{j}$ if $t_{0}>0$ is given by Theorem 1.12.
The situation is different for the branch point case.
Theorem 1.3. There exist two slits $\Gamma_{1}, \Gamma_{2}$ in $\mathbb{D}$ with $\overline{\Gamma_{1}} \cap \overline{\Gamma_{2}}=\{p\} \subset \partial \mathbb{D}$ with $\mathbb{D}$ Loewner parametrizations $\gamma_{k}:[0, T] \rightarrow \Gamma_{k}$ in $[0, T]$, such that the function $t \mapsto g_{t}(z)$, $z \in \Omega_{T}$, is not differentiable at $t=0$.

On the other hand, we also give a condition ensuring differentiability of $t \mapsto g_{t}(z)$ at $t=0$ in this case.

Definition 1.4. Let $\alpha \in(0, \pi)$. We say that a simple curve $\gamma:[0, T] \rightarrow \overline{\mathbb{D}}, \gamma(0) \in$ $\partial \mathbb{D}, \gamma(0, T] \subset \mathbb{D}$, approaches $\partial \mathbb{D}$ in $\alpha$-direction (see Figure 1) if for every $\varepsilon>0$ there exists $s>0$ such that

$$
\gamma(0, s] \subset\{z \in \mathbb{D} \mid \alpha-\varepsilon<\arg (\gamma(0)-z)+\arg (\gamma(0))-\pi / 2<\alpha+\varepsilon\}
$$

Theorem 1.5. Let $b_{1}, b_{2} \geq 0, \gamma_{1}(0)=\gamma_{2}(0)$ and assume that $\Gamma_{j}$ approaches $\partial \mathbb{D}$ in $\alpha_{j}$-direction with $\alpha_{1} \leq \alpha_{2}$. Let $\gamma_{j}$ be a $\mathbb{D}$-Loewner parametrization for $\Gamma_{j}$ at $t=0$ for $j=1$ and $j=2$ with $b_{1}=\dot{c}_{1}(0), b_{2}=\dot{c}_{2}(0)$. Then the function $t \mapsto g_{t}(z)$ is differentiable at $t=0$ for every $z \in \Omega$.

- If $b_{1}=0$ or $b_{2}=0$, then $\dot{c}(0)=\max \left\{b_{1}, b_{2}\right\}$. If $b_{1}, b_{2}>0$, then
- $\max \left\{b_{1}, b_{2}\right\} \leq \dot{c}(0)<b_{1}+b_{2}$,
- $\dot{c}(0)=\max \left\{b_{1}, b_{2}\right\}$ if and only if $\alpha_{1}=\alpha_{2}$, and
- $\dot{c}(0) \rightarrow b_{1}+b_{2}$ as $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$.

Note that the very last statement says that the branch point case behaves like the disjoint case when $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$, see (2).

Finally it is worth mentioning that the converse of Theorem 1.5 is wrong; see Example 2.6.

## The multiply connected case

A circular slit disk $D$ is an $n$-connected domain of the form $D=\mathbb{D} \backslash\left(C_{1} \cup \ldots \cup\right.$ $C_{n-1}$ ), where the $C_{j}$ 's are proper disjoint circular arcs in $\mathbb{D}$ centered at 0 . For any circular slit disk $D$ and any $u \in \partial \mathbb{D}$, we denote by $w \mapsto \Phi(u, w ; D)$ the unique conformal mapping from $D$ onto the right half-plane minus slits parallel to the imaginary axis with $\Phi(u, u ; D)=\infty$ and $\Phi(u, 0 ; D)=1$. For example, $\Phi(u, w ; \mathbb{D})=$ $\frac{u+w}{u-w}$.

Now let $\Omega$ be an $n$-connected circular slit disk and let $\gamma:[0, T] \rightarrow \overline{\mathbb{D}}$ be a simple curve with $\Gamma:=\gamma(0, T] \subset \Omega \backslash\{0\}$ and $\gamma(0) \in \partial \mathbb{D}$. In this case, $\Omega_{t}:=\Omega \backslash \gamma[0, t]$ is an $n$-connected domain for every $t \in[0, T]$ and it can be mapped onto a circular slit disk $D_{t}$ by a conformal map $g_{t}: \Omega_{t} \rightarrow D_{t}$. This mapping is unique if we require the normalization $g_{t}(0)=0, g_{t}^{\prime}(0)>0, g_{t}(\partial \mathbb{D}) \subset \partial \mathbb{D}$; see [4], Chapter 15.6. In the following, we will call mappings normalized if they satisfy these three conditions.

Again we define the logarithmic mapping radius $\operatorname{lmr}\left(g_{t}\right):=\log \left(g_{t}^{\prime}(0)\right)$. The ana$\log$ of Theorem A is given by the following theorem; see Theorem 5.1 in [1] or Theorem 2 in [2]. Loewner equations for multiply connected domains were first studied by Komatu; see [6] and [5].

Theorem B. The function $c(t):=\operatorname{lmr}\left(g_{t}\right)$ is differentiable at $t=t_{0}$ if and only if the family $\left\{g_{t}\right\}_{t \in[0, T]}$ is differentiable at $t=t_{0}$, i.e. for every $z \in \Omega \backslash \Gamma$, the function $t \mapsto g_{t}(z)$ is differentiable at $t=t_{0}$. In this case, $g_{t}(z)$ satisfies the following differential equation:

$$
\begin{equation*}
\dot{g}_{t_{0}}(z)=\dot{c}\left(t_{0}\right) \cdot g_{t_{0}}(z) \cdot \Phi\left(\xi\left(t_{0}\right), g_{t_{0}}(z) ; D_{t_{0}}\right) \tag{3}
\end{equation*}
$$

where $\xi\left(t_{0}\right)=\lim _{z \rightarrow \gamma\left(t_{0}\right)} g_{t_{0}}(z)$.

In the following, we will call $\gamma$ an $\Omega$-Loewner parametrization for $\Gamma$ at $t_{0}$, if the two equivalent conditions in Theorem B hold.

The following relation to $\mathbb{D}$-Loewner parametrizations is not surprising.
Theorem 1.6. Let $t_{0} \in[0, T]$. Then $\gamma$ is an $\Omega$-Loewner parametrization for $\Gamma$ at $t_{0}$ if and only if it is a $\mathbb{D}$-Loewner parametrization for $\Gamma$ at $t_{0}$.

Now we pass again to the case of two slits: Let $\gamma_{1}, \gamma_{2}:[0, T] \rightarrow \overline{\mathbb{D}}$ be parametrizations of two slits $\Gamma_{1}=\gamma(0, T]$ and $\Gamma_{2}=\gamma_{2}(0, T]$ such that $\Gamma_{1}$ and $\Gamma_{2}$ are disjoint, $\Gamma_{1}, \Gamma_{2} \subset \Omega \backslash\{0\}$ and $\gamma_{1}(0) \neq \gamma_{2}(0)$ or $\gamma_{1}(0)=\gamma_{2}(0)$.

Again, we define $g_{t}$ to be the unique normalized mapping from $\Omega_{t}:=\Omega \backslash\left(\gamma_{1}[0, t] \cup\right.$ $\left.\gamma_{2}[0, t]\right)$ onto a circular slit disk $\mathbb{D}_{t}$ and $\operatorname{lmr}\left(g_{t}\right):=\log \left(g_{t}^{\prime}(0)\right)$.

Furthermore, let $h_{t}$ be the unique normalized mapping from $\Psi_{t}:=\mathbb{D} \backslash\left(\gamma_{1}[0, t] \cup\right.$ $\left.\gamma_{2}[0, t]\right)$ onto $\mathbb{D}$.

Theorem 1.7. Let $t_{0} \in[0, T]$. Then the following two statements are equivalent.

1. The function $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Omega_{t_{0}}$.
2. The function $t \mapsto h_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Psi_{t_{0}}$.

In the branch point case, i.e. $\gamma_{1}(0)=\gamma_{2}(0)$ and $t_{0}=0$, the above statements are equivalent to each of the following two statements.
3. The function $t \mapsto \operatorname{lmr}\left(h_{t}\right)$ is differentiable at 0 .
4. The function $t \mapsto \operatorname{lmr}\left(g_{t}\right)$ is differentiable at 0 .

As a direct consequence of the last two theorems, we can state Theorem 1.2 and Theorem 1.5 for the multiply connected case.

Corollary 1.8. Suppose that $t_{0} \in[0, T]$ such that $\gamma_{1}\left(t_{0}\right) \neq \gamma_{2}\left(t_{0}\right)$. Then the following conditions are equivalent:

1. The function $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Omega_{t_{0}}$.
2. For $j=1,2, \gamma_{j}$ is a $\mathbb{D}$-Loewner parametrization for $\Gamma_{j}$ at $t_{0}$.

Corollary 1.8 shows that the question whether the function $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ can be reduced to the corresponding question for each single slit with respect to the simply connected domain $\mathbb{D}$.

Corollary 1.9. Suppose $\gamma_{1}(0)=\gamma_{2}(0)$ and that $\Gamma_{j}$ approaches $\partial \mathbb{D}$ in $\alpha_{j}$ direction with $\alpha_{1} \leq \alpha_{2}$. If $\gamma_{j}$ is a $\mathbb{D}$-Loewner parametrization for $\Gamma_{j}$ at $t=0$ for $j=1$ and $j=2$, then the function $t \mapsto g_{t}(z)$ is differentiable at $t=0$ for every $z \in \Omega$.

Remark 1.10. All statements presented here can be easily generalized to the case of $m>2$ slits and to slits that are branched within the unit disc.

We only consider the case of two slits and of one branch point on $\partial \mathbb{D}$ in order to simplify the notation in the proofs.

### 1.2. Organization of the paper

Before we pass on to the proofs of Theorems 1.2, 1.3, 1.5, 1.6 and 1.7, we will explain how Theorems 1.2, 1.6 and 1.7 follow from a more technical statement. To this end, we first introduce some further notations.

We denote by $\Omega$ an arbitrary circular slit disk.
Let $m=1$ or $m=2$ and let $\gamma_{1}, \ldots, \gamma_{m}:[0, T] \rightarrow \bar{\Omega} \backslash\{0\}$ be Jordan arcs with $\gamma_{k}(0) \in$ $\partial \mathbb{D}$ and $\Gamma_{k}:=\gamma_{k}(0, T] \subset \Omega$. In case $m=2$, we suppose that $\Gamma_{1}$ and $\Gamma_{2}$ are disjoint.

The normalized conformal mapping $g_{t}$ is defined as before, i.e. $g_{t}$ maps $\Omega_{t}:=$ $\Omega \backslash \bigcup_{k=1}^{m} \gamma_{k}[0, t]$ onto the circular slit disk $D_{t}$.

To simplify the notation, we will also write $\Phi(\xi, z ; t)$ instead of $\Phi\left(\xi, z ; D_{t}\right)$.

Beside $\Omega_{t}$, we set $\Delta_{k}(t):=\mathbb{D} \backslash \gamma_{k}[0, t]$. Note that $\Delta_{k}(t)$ is simply connected, whereas $\Omega_{t}$ is $n$-connected. As before, we denote by $h_{k ; t}: \Delta_{k}(t) \rightarrow \mathbb{D}$ the unique conformal mapping with the normalization $h_{t}(0)=0$ and $h_{t}^{\prime}(0)>0$.

Moreover, we will make use of the driving functions of $g_{t}$ and $h_{k ; t}$ defined by $\xi_{k}(t):=g_{t}\left(\gamma_{k}(t)\right)$ and $\zeta_{k}(t):=h_{k ; t}\left(\gamma_{k}(t)\right)$, respectively, for all $t \in[0, T]$ and all $k=$ $1, \ldots, m$.

Remark 1.11. We note that the driving functions $\xi_{k}, \zeta_{k}:[0, T] \rightarrow \partial \mathbb{D}$ are continuous by Proposition 8 from [2].

In order to give a connection between differentiability of $t \mapsto g_{t}(z)$ and $t \mapsto h_{k ; t}(z)$ we need one further abbreviation. Therefore we set

$$
\alpha_{k}(t): \left.=\left|\frac{d}{d z}\left(g_{t} \circ h_{k ; t}^{-1}\right)(z)\right|_{z=\zeta_{k}(t)} \right\rvert\,
$$

for all $t \in[0, T]$ and all $k=1, \ldots, m$. The derivative is well-defined, as $g_{t} \circ h_{k, t}^{-1}$ can be extended by the Schwarz refection principle to an analytic function at $z=\zeta_{k}(t)$.

Note that $\alpha_{k}(t) \leq 1$ holds for all $t \in[0, T]$ if $\Omega$ is simply connected, i.e. if $\Omega=\mathbb{D}$, see Lemma 3.7. Then we find the following theorem.

Theorem 1.12. Let $t_{0} \in[0, T]$ with $\gamma_{1}\left(t_{0}\right) \neq \gamma_{2}\left(t_{0}\right)$.
Let $z_{0} \in \Omega_{t_{0}} \backslash\{0\}$, then the following two conditions are equivalent.

1. Each function $t \mapsto h_{k ; t}\left(z_{0}\right)$ is differentiable at $t_{0}$ for every $k=1, \ldots, m$.
2. The function $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Omega_{t_{0}}$.

If $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Omega_{t_{0}}$, then

$$
\dot{g}_{t_{0}}(z)=g_{t_{0}}(z) \sum_{k=1}^{m} \lambda_{k}\left(t_{0}\right) \cdot \Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}(z) ; D_{t_{0}}\right),
$$

where $\lambda_{1}\left(t_{0}\right), \lambda_{2}\left(t_{0}\right)$ are uniquely determined non-negative numbers.
If $t \mapsto h_{k ; t}\left(z_{0}\right)$ is differentiable at $t_{0}$, then $t \mapsto h_{k ; t}(z)$ is differentiable at $t_{0}$ for every $z \in \Delta_{k}\left(t_{0}\right)$ and fulfills the following equation

$$
\dot{h}_{k ; t_{0}}(z)=h_{k ; t_{0}}(z) \cdot \mu_{k}\left(t_{0}\right) \cdot \frac{\zeta_{k}\left(t_{0}\right)+h_{k ; t_{0}}(z)}{\zeta_{k}\left(t_{0}\right)-h_{k ; t_{0}}(z)},
$$

where $\mu_{k}\left(t_{0}\right)=\left.\frac{d}{d t} \operatorname{lmr}\left(h_{k ; t}\right)\right|_{t=t_{0}} \geq 0$.
Moreover each function $t \mapsto \alpha_{k}(t)$ is continuous in $[0, T]$ for all $k=1, \ldots, m$ and it holds $\alpha_{k}(t)>0$ and $\lambda_{k}\left(t_{0}\right)=\alpha_{k}^{2}\left(t_{0}\right) \cdot \mu_{k}\left(t_{0}\right)$.

Remark 1.13. The value $\lambda_{k}\left(t_{0}\right)$ can be given explicitly:
Let $t, \tau \in[0, T]$, set

$$
\Omega_{k}(t, \tau):=\Omega \backslash\left(\gamma_{k}[0, t] \cup \bigcup_{\substack{j=1 \\ j \neq k}}^{m} \gamma_{j}[0, \tau]\right)
$$

and denote by $f_{k ; t, \tau}$ the unique normalized conformal mapping from $\Omega_{k}(t, \tau)$ onto a circular slit disk. Then

$$
\lambda_{k}\left(t_{0}\right)=\lim _{t \rightarrow t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t_{0}}\right)-\operatorname{lmr}\left(f_{k ; t_{0}, t_{0}}\right)}{t-t_{0}}
$$

see Lemma 3.1.
Remark 1.14. Note that Theorem 1.12 implies

- Theorem 1.2: consider the case $\Omega=\mathbb{D}$,
- Theorem 1.6: let $m=1$,
- Theorem 1.7 (disjoint case): apply Theorem 1.12 twice; first you pass from the multiply connected case with two slits to equation ( $* *$ ), then you pass to the simply connected case with two slits.

Thus, what remains to show are Theorems 1.3, 1.5, and 1.7 for the branch point case and Theorem 1.12.

The rest of this paper is organized as follows: The proof of Theorem 1.12 is given in Section 3 and in Section 4 we prove Theorems 1.3 and 1.5. The proof of Theorem 1.7 for the branch point case is given in Appendix A.

We start with Section 2, where we give three applications of Theorem 1.12.

## 2. Applications and examples

Theorem 1.12 can be used to prove several results concerning the Loewner equation for multiple slits. In this chapter we use the same notation as in Section 1.2 and we let $m=2$.

If we have no further information about the parametrizations $\gamma_{k}$ of the slits $\Gamma_{k}$ $(k=1,2)$, it is still possible to show that equation $(\star)$ holds for almost all $t \in[0, T]$.

First, as the functions $t \mapsto \operatorname{lmr}\left(h_{k ; t}\right)$ are strictly increasing, the derivatives $\mu_{1}(t), \mu_{2}(t)$ exist almost everywhere. Thus we immediately get from Theorem A that the functions $t \mapsto h_{k ; t}(z)$ are differentiable almost everywhere for all $z \in \Delta_{k}(T)$ and all $k=1,2$. Together with Theorem 1.12 we find the following corollary, which has been already proved in [2] by using different tools.

Corollary 2.1. (Corollary 5 in [2]) There exists a null-set $\mathcal{N}$ with respect to the Lebesgue measure such that the functions $t \mapsto g_{t}(z)$ are differentiable on $[0, T] \backslash \mathcal{N}$ for all $z \in \Omega_{T}$ and it holds

$$
\dot{g}_{t}(z)=g_{t}(z) \sum_{k=1}^{m} \lambda_{k}(t) \cdot \Phi\left(\xi_{k}(t), g_{t}(z) ; t\right)
$$

for all $t \in[0, T] \backslash \mathcal{N}$ and each $z \in \Omega_{t}$. Furthermore, the functions $\lambda_{k}\left(t_{0}\right)$ fulfill the condition $\sum_{k=1}^{m} \lambda_{k}\left(t_{0}\right)=1$ if the condition $g_{t}^{\prime}(0)=c e^{t}$ holds in a neighborhood of $t_{0}$ with some constant $c>0$.

Note that this is true for arbitrary parametrizations of the slits $\gamma_{k}$, i.e. we do not assume any normalization like $g_{t}^{\prime}(0)=e^{t}$.

Next we will demonstrate how Theorem 1.12 can be used to find new parametrizations for $\Gamma_{1}, \Gamma_{2}$, in order to get "nice" (Komatu-)Loewner equations, i.e. equations with differentiability everywhere (and not only almost everywhere).

First, we let $L:=\operatorname{lmr}\left(g_{T}\right)$ and $L_{k}:=\operatorname{lmr}\left(h_{k ; T}\right)$. Note that $L_{k}<L$ by the monotonicity of lmr.

Corollary 2.2. Assume $\gamma_{1}(0) \neq \gamma_{2}(0)$. Then there exist parametrizations $\widetilde{\gamma}_{1}, \widetilde{\gamma}_{2}:[0, L] \rightarrow \overline{\mathbb{D}}$ of the slits $\Gamma_{1}$ and $\Gamma_{2}$ such that the following holds: Denote by $\tilde{g}_{s}$ the unique normalized conformal mapping from $\widetilde{\Omega}_{s}:=\Omega \backslash\left(\widetilde{\gamma}_{1}[0, s] \cup \widetilde{\gamma}_{2}[0, s]\right)$ onto a circular slit disk $\widetilde{D}_{s}$ and let $\tilde{\xi}_{k}(s):=\tilde{g}_{s}\left(\widetilde{\gamma}_{k}(s)\right)$.

Then the function $s \mapsto \tilde{g}_{s}$ is continuously differentiable in $[0, L]$ with

$$
\begin{equation*}
\dot{\tilde{g}}_{s}(z)=\tilde{g}_{s}(z) \sum_{k=1}^{2} \tilde{\lambda}_{k}(s) \cdot \Phi\left(\tilde{\xi}_{k}(s), \tilde{g}_{s}(z), \widetilde{D}_{s}\right), \quad \text { for all } s \in[0, L] \tag{4}
\end{equation*}
$$

with continuous functions $\tilde{\xi}_{k}(s), \tilde{\lambda}_{k}(s) \geq 0$ and $\tilde{\lambda}_{1}(s)+\tilde{\lambda}_{2}(s)=1$ for all $s \in[0, L]$.
Proof. First of all we assume that each slit $\Gamma_{k}$ is parameterized in such a way that $\operatorname{lmr}\left(h_{k ; t}\right)$ is continuously differentiable for all $t \in[0, T]$, e.g. $\operatorname{lmr}\left(h_{k ; t}\right)=\frac{L_{k}}{T} \cdot t$. (If not, then we can reparametrize $\gamma_{1}$ and $\gamma_{2}$.)

In the notation of Theorem 1.12, this means that $\mu_{k}(t)=\frac{L_{k}}{T}$ for all $t \in[0, T]$.
Then, by Theorem A and Remark 1.11, the trajectories $t \mapsto h_{k ; t}(z)$ are continuously differentiable and fulfill equation $(\star \star)$ for each $t \in[0, T]$.

By Theorem 1.12, the trajectories $t \mapsto g_{t}(z)$ fulfill equation ( $\star$ ) for all $t \in[0, T]$. The right side of equation $(\star)$ depends continuously on $t$ :
the driving functions are continuous because of Remark 1.11, and Lemma 19 in [2] implies the continuity of the function $\Phi$. The continuity of the weights $t \mapsto \lambda_{k}(t)$
is an immediate consequence of the relation $\lambda_{k}(t)=\alpha_{k}^{2}(t) \cdot \mu_{k}(t)$ (see Theorem 1.12) together with the continuity of $\alpha_{k}$ and $\mu_{k}$.

Hence, $t \mapsto g_{t}(z)$ is continuously differentiable in $[0, T]$.
Note that, in general, the weights $t \mapsto \lambda_{k}(t)$ don't sum up to 1 .
In order to get normalized weights, we consider the following increasing homeomorphism $u(t):=\operatorname{lmr}\left(g_{t}\right)=\operatorname{lmr}\left(\gamma_{1}[0, t] \cup \gamma_{2}[0, t]\right)$ that maps $[0, T]$ onto $[0, L]$. It is continuously differentiable with $\dot{u}(t)=\lambda_{1}(t)+\lambda_{2}(t)$ for all $t \in[0, T]$. This follows easily by differentiating $(\star)$ w.r.t. $z$ at the point $z=0$.

Now we set $\widetilde{\gamma}_{k}(s):=\gamma_{k}\left(u^{-1}(s)\right)$ for all $s \in[0, L]$. Since the function $s \mapsto$ $\operatorname{lmr}\left(\widetilde{\gamma}_{k}[0, s]\right)$ is the composition of two continuously differentiable functions it is continuously differentiable as well. Consequently, by using Theorem 1.12 in the same way as before, the trajectories $s \mapsto \tilde{g}_{s}(z)$ are continuously differentiable and fulfill the stated differential equation for all $s \in[0, L]$.

Finally, as $\operatorname{lmr}\left(\tilde{g}_{s}\right)=s$ for all $s \in[0, L]$, we have $\tilde{\lambda}_{1}(s)+\tilde{\lambda}_{2}(s)=1$ for all $s \in$ $[0, L]$.

Remark 2.3. The proof of Corollary 2.2 shows that there exist "many" parametrizations $\widetilde{\gamma}_{1}, \widetilde{\gamma}_{2}$ such that (4) holds and tells us how to construct them. This is based on the fact that we are not restricted to claim $\operatorname{lmr}\left(h_{k ; t}\right)=\frac{L_{k}}{T} \cdot t$. Instead, we can choose the initial parametrization in such a way that $\operatorname{lmr}\left(h_{k ; t}\right)=u_{k}(t)$ holds, where $u_{k}:[0, T] \rightarrow\left[0, L_{k}\right]$ is an arbitrary continuously differentiable increasing homeomorphism.

In [3] it was shown that one can even choose $\widetilde{\gamma}_{1}$ and $\widetilde{\gamma}_{2}$ such that $\tilde{\lambda}_{1}(t)$ and $\tilde{\lambda}_{2}(t)$ are constant. Furthermore, this additional condition makes $\widetilde{\gamma}_{1}$ and $\widetilde{\gamma}_{2}$ unique.

The next application is a bit more technical, but quite useful, e.g. for constructing certain counterexamples mentioned in the introduction.

Assume that $u_{1}:[0, L] \rightarrow\left[0, L_{1}\right]$ is a given increasing homeomorphism. It is easy to see that we can find an increasing homeomorphism $v_{1}:[0, L] \rightarrow[0, T]$, such that $\operatorname{lmr}\left(h_{1, v_{1}(s)}\right)=u_{1}(s)$ for all $s \in[0, L]$. Now consider the following question:

Can we find an increasing homeomorphism $v_{2}:[0, L] \rightarrow[0, T]$ such that the function $s \mapsto \tilde{g}_{s}$ from Corollary 2.2 satisfies (4) with $\tilde{\lambda}_{1}(s)+\tilde{\lambda}_{2}(s)=1$ for all $s \in[0, L]$ ?

The following statement gives a partial answer to this question for the simply connected case, i.e. $\Omega=\mathbb{D}$. The proof depends on an inequality for the logarithmic mapping radius (see inequality (7)) that is only known to be true for the simply connected case.

Proposition 2.4. Assume $\gamma_{1}(0) \neq \gamma_{2}(0)$. Let $\Omega=\mathbb{D}$ and $u_{1}:[0, L] \rightarrow\left[0, L_{1}\right]$ be an increasing Lipschitz continuous function with a Lipschitz constant $K<1$.

Let $v_{1}:[0, L] \rightarrow[0, T]$ be the increasing homeomorphism such that $\operatorname{lmr}\left(h_{1, v_{1}(s)}\right)=$ $u_{1}(s)$ for all $s \in[0, L]$. Then there is a unique increasing homeomorphism $v_{2}:[0, L] \rightarrow$ $[0, T]$ such that the following holds:

Denote by $\tilde{g}_{s}$ the unique normalized conformal mapping from $\Omega_{s}:=\mathbb{D} \backslash\left(\left(\gamma_{1} \circ\right.\right.$ $\left.\left.v_{1}\right)[0, s] \cup\left(\gamma_{2} \circ v_{2}\right)[0, s]\right)$ onto $\mathbb{D}$. Then $\operatorname{lmr}\left(\tilde{g}_{s}\right)=s$ for all $s \in[0, L]$.

Moreover, if $s \mapsto u_{1}(s)$ is continuously differentiable in $[0, L]$, then the function $s \mapsto \tilde{g}_{s}(z)$ is continuously differentiable and satisfies (4) for all $s \in[0, L]$ and all $z \in$ $\mathbb{D} \backslash\left(\Gamma_{1} \cup \Gamma_{2}\right)$ with $\tilde{\lambda}_{1}(s)+\tilde{\lambda}_{2}(s)=1$ for all $s \in[0, L]$.

The proof of this proposition is given in Section 3.
Example 2.5. Let $\Omega=\mathbb{D}$ and $\Gamma_{1}, \Gamma_{2}$ be disjoint slits with $L=1$. Then $L_{1}, L_{2}<1$. Consequently we find an $\varepsilon>0$ so that $L_{1}+\varepsilon<1$ as well. Then we define

$$
u_{1}:[0,1] \longrightarrow\left[0, L_{1}\right], \quad s \longmapsto u_{1}(s):= \begin{cases}\left(L_{1}+\varepsilon\right) s & \text { if } t \in\left[0, \frac{1}{2}\right] \\ \left(L_{1}-\varepsilon\right) s+\varepsilon & \text { if } s \in\left(\frac{1}{2}, 1\right]\end{cases}
$$

By $v_{1}:[0,1] \rightarrow\left[0, L_{1}\right]$ we denote the homeomorphism such that $\operatorname{lmr}\left(h_{1 ; v_{1}(s)}\right)=u_{1}(s)$.
$u_{1}$ is Lipschitz continuous with Lipschitz constant $K=L_{1}+\varepsilon<1$. By Proposition 2.4 we find a homeomorphism $v_{2}:[0,1] \rightarrow\left[0, L_{2}\right]$ so that $\operatorname{lmr}\left(\tilde{g}_{s}\right)=s$ for all $s \in[0,1]$.

The function $s \mapsto h_{1 ; v_{1}(s)}$ is not differentiable at $s=\frac{1}{2}$ by Theorem A as $u_{1}(s)=$ $\operatorname{lmr}\left(h_{1, v_{1}(s)}\right)$ is not differentiable at $s=\frac{1}{2}$.

Thus, by Theorem 1.12, the function $s \mapsto \tilde{g}_{s}$ is not differentiable at $s=\frac{1}{2}$. However, the function $s \mapsto \operatorname{lmr}\left(\tilde{g}_{s}\right)=s$ is differentiable at $s=\frac{1}{2}$.

Finally, we consider the slightly different setting of two slits with one common starting point. The next example shows that the converse of Theorem 1.5 is not true.

Example 2.6. Let $\gamma_{1}, \gamma_{2}:[0, T] \rightarrow \overline{\mathbb{D}}$ be parametrizations of two slits satisfying the conditions of Theorem 1.5. Let $g_{t}$ be defined as in Theorem 1.5.

Furthermore, let $h_{k ; t}$ be the unique normalized mapping from $\mathbb{D} \backslash \gamma_{k}[0, t]$ onto $\mathbb{D}$.
Without restricting generality we may assume $L:=\operatorname{lmr}\left(g_{T}\right)=1$. Moreover, let $L_{k}:=\operatorname{lmr}\left(h_{k ; T}\right)$. Then $L_{k}<1$ and we find analogously to Example 2.5 an $\varepsilon>0$ so that $L_{1}+\varepsilon<1$.

Next, let $u:[0,1] \rightarrow\left[0, L_{1}\right]$ be defined by

$$
s \longmapsto u(s)= \begin{cases}\left(L_{1}+\varepsilon\right) s & \text { if } t \in\left[0, \frac{1}{2}\right] \\ \left(L_{1}-\varepsilon\right) s+\varepsilon & \text { if } s \in\left(\frac{1}{2}, 1\right] .\end{cases}
$$

Figure 2. The function $u_{1}$ from Example 2.6.

We will use $u$ to construct another increasing homeomorphism $u_{1}:[0,1] \rightarrow\left[0, L_{1}\right]$ (see Figure 2):

$$
u_{1}(s):= \begin{cases}\frac{1}{2^{n}} u\left(2^{n} s-1\right)+\frac{L_{1}}{2^{n}} & \text { if } s \in\left(\frac{1}{2^{n}}, \frac{2}{2^{n}}\right] \text { with } n \in \mathbb{N} \\ 0 & \text { if } s=0\end{cases}
$$

We have $\left|u_{1}\left(t_{2}\right)-u_{1}\left(t_{1}\right)\right| \leq\left(L_{1}+\varepsilon\right)\left(t_{2}-t_{1}\right)$ for all $0 \leq t_{1} \leq t_{2} \leq 1$, so $u_{1}$ is strictly increasing and Lipschitz continuous. Moreover we denote by $v_{1}:[0,1] \rightarrow[0, T]$ the unique homeomorphism having the property that $\operatorname{lmr}\left(h_{1 ; v_{1}(s)}\right)=u_{1}(s)$ holds for all $s \in[0,1]$. Now we find a unique homeomorphism $v_{2}:[0,1] \rightarrow[0, T]$ such that $\operatorname{lmr}\left(\tilde{g}_{s}\right)=s$ holds for all $s \in[0,1]$, where $\tilde{g}_{s}$ denotes the unique normalized mapping from $\mathbb{D} \backslash\left(\left(\gamma_{1} \circ v_{1}\right)[0, s] \cup\left(\gamma_{2} \circ v_{2}\right)[0, s]\right)$ onto $\mathbb{D}$. This is possible to do using the first part of the proof of Proposition 2.4, as it is applicable to the branch point case as well.

On the one hand, by Theorem 1.7, the function $s \mapsto \tilde{g}_{s}$ is differentiable at $s=0$. On the other hand, $s \mapsto h_{1 ; v_{1}(s)}$ is not differentiable at $s=0$ in accordance with Theorem A, because by construction, $\operatorname{lmr}\left(h_{1 ; v_{1}(s)}\right)=u_{1}(s)$ and $u_{1}^{\prime}(0)$ does not exist.

## 3. Proof of Theorem 1.12 and Proposition 2.4

As we have mentioned in the introduction, all statements can be easily generalized to the case $m>2$, so we will use a notation indicating this case as well.

First of all, for all $t, \tau \in[0, T]$, we set

$$
\Omega_{k}(t, \tau):=\Omega \backslash\left(\gamma_{k}[0, t] \cup \bigcup_{\substack{j=1 \\ j \neq k}}^{m} \gamma_{j}[0, \tau]\right)
$$

and denote by $f_{k ; t, \tau}$ the unique normalized mapping $f_{t}: \Omega_{k}(t, \tau) \rightarrow D_{k}(t, \tau)$, where $D_{k}(t, \tau)$ is a circular slit disk. Consequently we have $g_{t}=f_{k ; t, t}$ and $\Omega_{t}=\Omega_{k}(t, t)$ as well.

Next, provided that the limits exist, we define

$$
\lambda_{k}\left(t_{0}\right):=\lim _{t \rightarrow t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t_{0}}\right)-\operatorname{lmr}\left(f_{k ; t_{0}, t_{0}}\right)}{t-t_{0}} \quad \text { and } \quad \mu_{k}\left(t_{0}\right):=\lim _{t \rightarrow t_{0}} \frac{\operatorname{lmr}\left(h_{k ; t}\right)-\operatorname{lmr}\left(h_{k ; t_{0}}\right)}{t-t_{0}} .
$$

Finally we set $\xi_{k}(t, \tau):=f_{k ; t, \tau}\left(\gamma_{k}(t)\right)$,

$$
S_{k ; t, \bar{t}, \tau}:=f_{k ; \underline{t}, \tau}\left(\gamma_{k}[\underline{t}, \bar{t}]\right) \subset \mathbb{D} \cup\left\{\xi_{k}(t, \tau)\right\} \quad \text { and } \quad s_{k ; t, \bar{t}, \tau}:=f_{k ; \bar{t}, \tau}\left(\gamma_{k}[\underline{,}, \bar{t}]\right) \subset \partial \mathbb{D}
$$

and $\sigma_{k ; t, t, t}:=h_{k ; \bar{t}}\left(\gamma_{k}[\underline{t}, \bar{t}]\right)$ for all $0 \leq \underline{t} \leq \bar{t} \leq T$. Next we are going to use results from [2] in order to show that the existence of the above limits $\lambda_{k}\left(t_{0}\right)$ is equivalent to differentiability of the function $t \mapsto g_{t}(z)$.

Lemma 3.1. Let $t_{0} \in[0, T]$. Then the following three conditions are equivalent:

1. Each limit $\lambda_{k}\left(t_{0}\right)$ exists $(k=1, \ldots, m)$.
2. The function $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Omega_{t_{0}}$.
3. The function $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ for every $z \in \Omega_{t_{0}}$ and fulfills equation $(\star)$ for all $z \in \Omega_{t_{0}}$.

Proof. First of all note that (1.) $\Rightarrow$ (3.) follows immediately from Theorem 2 of [2]. On top of this, $(3.) \Rightarrow(2$.$) is trivial, so the only thing we are going to prove$ is $(2.) \Rightarrow(1$.$) .$

For this, let $t_{0} \in[0, T]$ and $t>t_{0}$. The other case $t<t_{0}$ can be treated in the same way. Since $t \mapsto g_{t}(z)$ is differentiable at $t_{0}$ so is $t \mapsto \log \left(g_{t}(z)\right)$ for every $z \in \Omega_{t_{0}} \backslash\{0\}$. The function $\log \left(g_{t}(z)\right)$ is multiple valued, but its derivative is single valued, so the following limit exists and is independent of the branch of the logarithm:

$$
\lim _{t \searrow t_{0}} \frac{1}{t-t_{0}} \operatorname{Re}\left(\log \frac{g_{t}(z)}{g_{t_{0}}(z)}\right)=\lim _{t \searrow t_{0}} \frac{1}{t-t_{0}} \ln \left|\frac{g_{t}(z)}{g_{t_{0}}(z)}\right| .
$$

Next we use Lemma 10 from [2] and the mean value theorem to get

$$
\ln \left|\frac{g_{t}(z)}{g_{t_{0}}(z)}\right|=\frac{1}{2 \pi} \sum_{k=1}^{m} \int_{s_{k ; t_{0}, t, t}}-\ln \left|\left(g_{t_{0}} \circ g_{t}^{-1}\right)(\xi)\right| \operatorname{Re}\left(\Phi\left(\xi, g_{t}(z) ; t\right)\right)|d \xi|
$$

$$
\begin{equation*}
=\frac{1}{2 \pi} \sum_{k=1}^{m} \operatorname{Re}\left(\Phi\left(\xi_{t, t_{0}}^{(k)}, g_{t}(z) ; t\right)\right) \int_{s_{k ; t_{0}, t, t}}-\ln \left|\left(g_{t_{0}} \circ g_{t}^{-1}\right)(\xi)\right||d \xi| . \tag{5}
\end{equation*}
$$

Note that $\Phi\left(\xi_{t, t_{0}}^{(k)}, g_{t}(z) ; t\right)$ tends to $\Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}(z) ; t_{0}\right)$ as $t \searrow t_{0}$ by Lemma 19 from [2].
This is based on the fact $s_{k ; t_{0}, t, t} \ni \xi_{t, t_{0}}^{(k)} \rightarrow \xi_{k}\left(t_{0}\right)$ as $t \searrow t_{0}$, see Proposition 8 from [2]. We write

$$
\int_{s_{k ; t_{0}, t, t}}-\ln \left|\left(g_{t_{0}} \circ g_{t}^{-1}\right)(\xi)\right||d \xi|=: c_{k}\left(t, t_{0}\right)
$$

Note that for each $k \in\{1, \ldots, m\}, \operatorname{Re}\left(\Phi\left(\xi_{t, t_{0}}^{(k)}, g_{t}(z) ; t\right)\right)$ and $c_{k}\left(t, t_{0}\right)$ are positive. Moreover, the limit $\lim _{t \backslash t_{0}} \frac{1}{t-t_{0}} \ln \left|g_{t}(z) / g_{t_{0}}(z)\right|$ exists by assumption for any $z \in \Omega_{t_{0}}$.
Summarizing, (5) shows that $\frac{c_{k}\left(t, t_{0}\right)}{t-t_{0}}$ is bounded for all $t \in\left(t_{0}, T\right]$. Together with Lemma 19 from [2] we find

$$
\begin{equation*}
\ln \left|\frac{g_{t}(z)}{g_{t_{0}}(z)}\right|=\frac{1}{2 \pi} \sum_{k=1}^{m} \operatorname{Re}\left(\Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}(z) ; t_{0}\right)\right) c_{k}\left(t, t_{0}\right)+o\left(\left|t-t_{0}\right|\right) \tag{6}
\end{equation*}
$$

From the proof of Theorem 2 of [2] we can see that $\lambda_{k}^{+}\left(t_{0}\right):=$ $\lim _{t \backslash t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t t_{0}}\right)-\operatorname{lmr}\left(f_{\left.k ; t_{0}, t_{0}\right)}\right)}{t-t_{0}}$ exists if and only if $\lim _{t \searrow t_{0}} \frac{c_{k}\left(t, t_{0}\right)}{t-t_{0}}$ exists. Consequently we are going to prove the existence of the limit $\lim _{t \backslash t_{0}} \frac{c_{k}\left(t, t_{0}\right)}{t-t_{0}}$.

For this purpose we show that we find $z_{1}, \ldots, z_{m} \in \Omega_{t_{0}}$ (independently of $t$ ) such that the matrix $A:=\left[a_{j, k}\right]_{j, k=1}^{m}$, with $a_{j, k}:=\operatorname{Re}\left(\Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}\left(z_{j}\right) ; t_{0}\right)\right)$, is invertible. Then, (6) yields

$$
\left(c_{1}\left(t, t_{0}\right), \ldots, c_{m}\left(t, t_{0}\right)\right)^{T}=\frac{1}{2 \pi} A^{-1}\left(\ln \left|\frac{g_{t}(z)}{g_{t_{0}}\left(z_{1}\right)}\right|, \ldots, \ln \left|\frac{g_{t}(z)}{g_{t_{0}}\left(z_{m}\right)}\right|\right)^{T}+o\left(\left|t-t_{0}\right|\right)
$$

and the existence of the limits $\lim _{t \backslash t_{0}} \frac{c_{k}\left(t, t_{0}\right)}{t-t_{0}}$ follows immediately.
To find $z_{1}, \ldots, z_{m}$, recall that $\Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}\left(\gamma_{k}\left(t_{0}\right)\right) ; t_{0}\right)=\infty$ and $\operatorname{Re}\left(\Phi\left(\xi_{k}\left(t_{0}\right)\right.\right.$, $\left.\left.g_{t_{0}}\left(\gamma_{j}\left(t_{0}\right)\right) ; t_{0}\right)\right)=0$ if $j \neq k$. For $k \in\{1, \ldots, m\}$ consider the preimage $L_{k}$ of the curve $\delta(x):=1+i x, x \geq 0$, under the mapping $z \mapsto \Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}(z) ; t_{0}\right)$. Since $L_{k}$ is a slit in $\Omega\left(t_{0}\right)$ landing at the point $\gamma_{k}\left(t_{0}\right), \operatorname{Re}\left(\Phi\left(\xi_{j}\left(t_{0}\right), g_{t_{0}}(z) ; t_{0}\right)\right) \rightarrow 0$ as $z \in L_{k}$ tends to $\partial \Omega\left(t_{0}\right)$ when $j \neq k$, while $\operatorname{Re}\left(\Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}(z) ; t_{0}\right)\right)=1$ for all $z \in L_{k}$ by construction.

Thus we can choose $z_{k} \in \Omega\left(t_{0}\right)$ close enough to $\gamma_{k}\left(t_{0}\right)$ in order to get

$$
\operatorname{Re}\left(\Phi\left(\xi_{k}\left(t_{0}\right), g_{t_{0}}\left(z_{k}\right) ; t_{0}\right)\right)=1 \quad \text { and } \quad \operatorname{Re}\left(\Phi\left(\xi_{j}\left(t_{0}\right), g_{t_{0}}\left(z_{k}\right) ; t_{0}\right)\right)<\frac{1}{m} \text { for all } j \neq k
$$

Consequently the matrix $A$ is a diagonally dominant matrix, so it is invertible as well.

The next lemma is a similar statement for the functions $h_{k ; t}$. Note, however, that here we only need differentiability of $t \mapsto h_{k ; t}\left(z_{0}\right)$ for one fixed $z_{0} \in \Delta_{k}\left(t_{0}\right) \backslash\{0\}$.

Lemma 3.2. Let be $t_{0} \in[0, T], z_{0} \in \Delta_{k}\left(t_{0}\right) \backslash\{0\}$ and $k \in\{1, \ldots, m\}$. Then the following three conditions are equivalent

1. The limit $\mu_{k}\left(t_{0}\right)$ exists.
2. The function $t \mapsto h_{k ; t}\left(z_{0}\right)$ is differentiable at $t_{0}$.
3. The function $t \mapsto h_{k ; t}(z)$ is differentiable at $t_{0}$ for every $z \in \Delta_{k}\left(t_{0}\right)$ and fulfills equation ( $* *$ ) for all $z \in \Delta_{k}(t)$.

Proof. First of all note that (1.) $\Rightarrow$ (3.) follows immediately from Theorem 2 from [2]. On top of this, $(3.) \Rightarrow(2$.$) is trivial, so the only thing we need to prove is$ $(2.) \Rightarrow(1$.$) .$

Let $t>t_{0}$ and $k \in\{1, \ldots, m\}$. Analogous to the proof of the previous lemma, we find

$$
\begin{aligned}
\log \left(\frac{h_{k ; t}\left(z_{0}\right)}{h_{k ; t_{0}}\left(z_{0}\right)}\right) & =\frac{1}{2 \pi} \int_{\sigma_{k ; t, t_{0}}}-\ln \left|\left(h_{k ; t_{0}} \circ h_{k ; t}^{-1}\right)(\zeta)\right| \frac{\zeta_{k}(t)+h_{k ; t}\left(z_{0}\right)}{\zeta_{k}(t)-h_{k ; t}\left(z_{0}\right)}|d \zeta| \\
& =\frac{\zeta_{k}\left(t_{0}\right)+h_{k ; t_{0}}\left(z_{0}\right)}{\zeta_{k}\left(t_{0}\right)-h_{k ; t_{0}}\left(z_{0}\right)} \frac{1}{2 \pi} \int_{\sigma_{k ; t, t_{0}}}-\ln \left|\left(h_{k ; t_{0}} \circ h_{k ; t}^{-1}\right)(\zeta)\right||d \zeta|+o\left(\left|t-t_{0}\right|\right) .
\end{aligned}
$$

The other case $t<t_{0}$ holds in the same way. From the proof of Theorem 2 of [2] we can see that the limit

$$
\lim _{t \searrow t_{0}} \frac{1}{t-t_{0}} \int_{\sigma_{k ; t, t_{0}}}-\ln \left|\left(h_{k ; t_{0}} \circ h_{k ; t}^{-1}\right)(\zeta)\right||d \zeta|
$$

exists if and only if $\mu_{k}^{+}\left(t_{0}\right)$ exists, where

$$
\mu_{k}^{+}\left(t_{0}\right):=\lim _{t \searrow t_{0}} \frac{\operatorname{lmr}\left(h_{k ; t}\right)-\operatorname{lmr}\left(h_{k ; t_{0}}\right)}{t-t_{0}}
$$

Since $t \mapsto h_{k ; t}\left(z_{0}\right)$ is differentiable at $t_{0}$ the proof is complete
Remark 3.3. The implication $(2.) \Rightarrow(3$.) in the previous lemma says that differentiability of $t \mapsto h_{k ; t}(z)$ at $t_{0}$ for just one point $z_{0} \in \Delta_{k}\left(t_{0}\right) \backslash\{0\}$ implies differentiability at $t_{0}$ for all $z \in \Delta_{k}\left(t_{0}\right)$.

We don't know whether the same is true in the case of $m>1$ slits. Note, however, that the proof of Lemma 3.1 shows that there are $m$ points such that differentiability of $t \mapsto g_{t}\left(z_{1}\right), \ldots, t \mapsto g_{t}\left(z_{m}\right)$ at $t_{0}$ together implies differentiability of $t \mapsto g_{t}(z)$ for all $z \in \Omega_{t_{0}}$.

Before we can proof Theorem 1.12, we need some preliminary lemmas.
Lemma 3.4. Let $A, B \subset \mathbb{D}$ be bounded domains and assume there exists an $R>0$ so that

$$
A \cap B_{R}(1)=B \cap B_{R}(1)=\mathbb{D} \cap B_{R}(1)
$$

holds, where $B_{R}\left(z_{0}\right):=\left\{z \in \mathbb{C}| | z-z_{0} \mid<R\right\}$. Moreover let $T: A \rightarrow B$ be a conformal mapping from $A$ onto $B$, where $T(1)=1$.

Then $c:=T^{\prime}(1)>0$ and for any $\delta>0$ there exists $\varepsilon>0$ such that the inequality

$$
|z|^{c+\delta} \leq|T(z)| \leq|z|^{c-\delta}
$$

holds for all $z \in A \cap B_{\varepsilon}(1)$.
Proof. First of all, we can extend the function $T$ to a conformal map in $B_{R}(1)$ by using the Schwarz reflection principle. As the $\operatorname{arc} \partial \mathbb{D} \cap B_{R}(1)$ is mapped onto an $\operatorname{arc}$ of $\partial \mathbb{D}$ and $T(1)=1$, we have $c:=T^{\prime}(1)>0$.

Now we can choose $\varepsilon \in(0, R)$ small enough such that

$$
\left|\frac{T^{\prime}(z)}{T(z)}-\frac{c}{z}\right|<\delta, \quad \text { for all } z \in B_{\varepsilon}(1)
$$

Next we set $\gamma_{\theta}(r):=r \cdot e^{i \theta}$ for all $r \in\left[r_{0}, 1\right]$ and all $|\theta|<\phi$. Hereby we can choose $r_{0}$ close enough to 1 and $\phi>0$ small enough to get $\gamma_{\theta}(r) \in B_{\varepsilon}(1)$ for all $r \in\left[r_{0}, 1\right]$ and all $\theta \in(-\phi, \phi)$. Moreover, for $r \in\left[r_{0}, 1\right]$ and $\theta \in(-\phi, \phi)$, we define

$$
h_{\theta}(r):=\operatorname{Re}\left(\log \frac{T\left(\gamma_{\theta}(r)\right)}{\left(\gamma_{\theta}(r)\right)^{c}}\right)=\ln \left|\frac{T\left(\gamma_{\theta}(r)\right)}{\left(\gamma_{\theta}(r)\right)^{c}}\right| .
$$

Note that there is an analytic branch of the logarithm of $\frac{T(z)}{z^{c}}$ in $B_{\varepsilon}(1)$, so we find

$$
\begin{aligned}
\left|\frac{\partial}{\partial r} h_{\theta}(r)\right| & =\left|\operatorname{Re}\left(\left.\frac{d}{d z} \log \left(\frac{T(z)}{z^{c}}\right)\right|_{z=\gamma_{\theta}(r)} \cdot \dot{\gamma}_{\theta}(r)\right)\right| \\
& =\left|\operatorname{Re}\left(\left.\left(\frac{T^{\prime}(z)}{T(z)}-\frac{c}{z}\right)\right|_{z=\gamma_{\theta}(r)} \cdot e^{i \theta}\right)\right| \\
& \left.\leq\left|\frac{T^{\prime}(z)}{T(z)}-\frac{c}{z}\right|_{z=\gamma_{\theta}(r)} \right\rvert\, \leq \delta .
\end{aligned}
$$

Moreover, we have $h_{\theta}(1)=0$ so we find

$$
\ln \left(r^{\delta}\right)=\delta \ln (r) \leq h_{\theta}(r) \leq-\delta \ln (r)=\ln \left(r^{-\delta}\right)
$$

Finally we get $\ln \left(|z|^{\delta}\right) \leq\left|\frac{T(z)}{z^{c}}\right| \leq \ln \left(|z|^{-\delta}\right)$ for all $z \in\left\{r \cdot e^{i \theta} \mid r \in\left[r_{0}, 1\right], \theta \in(-\phi, \phi)\right\}$, so the proof is complete.

Lemma 3.5. The function $t \mapsto \alpha_{k}(t)$ is continuous and positive for all $t \in[0, T]$. Moreover, for $t_{0} \in[0, T]$,

$$
\left|\left(f_{k ; t, \tau} \circ h_{k ; t}^{-1}\right)^{\prime}(a)\right| \longrightarrow \alpha_{k}\left(t_{0}\right)
$$

as $[0, T]^{2} \times \partial \mathbb{D} \ni(t, \tau, a) \rightarrow\left(t_{0}, t_{0}, \zeta_{k}\left(t_{0}\right)\right)$.
Proof. First of all, $\alpha_{k}(t)$ is positive, as the mapping $g_{t} \circ h_{k ; t}^{-1}$ can be extended analytically to a conformal map in a small neighborhood around $\zeta(t)$. Consequently the derivative can not vanish.

The continuity of $\alpha_{k}$ follows from the second statement of the lemma, which we are going to prove below, because

$$
\left|\left(f_{k ; t, t} \circ h_{k ; t}^{-1}\right)^{\prime}\left(\zeta_{k}(t)\right)\right|=\alpha_{k}(t)
$$

holds for all $t \in[0, T]$ and because $\partial \mathbb{D} \ni \zeta_{k}(t) \rightarrow \zeta_{k}\left(t_{0}\right)$ as $t \rightarrow t_{0}$ by Remark 1.11.
Note that we find an $\varepsilon>0$, so that the mapping $H_{k ; t, \tau}:=f_{k ; t, \tau} \circ h_{k ; t}^{-1}$ extends analytically to $B_{\varepsilon}\left(\zeta_{k}(t)\right)$ by the Schwarz reflection principle. Since $\zeta_{k}(t) \rightarrow \zeta_{k}\left(t_{0}\right)$ as $t$ tends to $t_{0}$, we find a small neighborhood $U$ around $\zeta_{k}\left(t_{0}\right)$, where $H_{k ; t, \tau}$ is analytic if $t$ and $\tau$ are close enough to $t_{0}$. By Proposition 7 from [2], $H_{k ; t, \tau}$ converges locally uniformly in $U \cap \mathbb{D}$ to $H_{k ; t_{0}, t_{0}}$ as $(t, \tau) \rightarrow\left(t_{0}, t_{0}\right)$. Using a normality argument, it is easy to see that $H_{k ; t, \tau}$ converges in fact locally uniformly on $U$ to $H_{k ; t_{0}, t_{0}}$, so we have

$$
H_{k ; t, \tau}(a) \longrightarrow H_{k ; t_{0}, t_{0}}\left(\zeta_{k}\left(t_{0}\right)\right) \quad \text { as }[0, T]^{2} \times \partial \mathbb{D} \ni(t, \tau, a) \longrightarrow\left(t_{0}, t_{0}, \zeta_{k}\left(t_{0}\right)\right)
$$

Finally, we find $\left|H_{k ; t, \tau}^{\prime}(a)\right| \rightarrow\left|H_{k ; t_{0}, t_{0}}^{\prime}\left(\zeta_{k}\left(t_{0}\right)\right)\right|=\alpha_{k}\left(t_{0}\right)$ as $(t, \tau, a) \rightarrow\left(t_{0}, t_{0}, \zeta_{k}\left(t_{0}\right)\right)$, so the proof is complete.

Lemma 3.6. Let be $t_{0} \in[0, T]$ and $k \in\{1, \ldots, m\}$. Then

$$
\lim _{t \rightarrow t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t_{0}}\right)-\operatorname{lmr}\left(f_{k ; t_{0}, t_{0}}\right)}{\operatorname{lmr}\left(h_{k ; t}\right)-\operatorname{lmr}\left(h_{k ; t_{0}}\right)}=\alpha_{k}^{2}\left(t_{0}\right) .
$$

Consequently the limit $\lambda_{k}\left(t_{0}\right)$ exists if and only if the limit $\mu_{k}\left(t_{0}\right)$ exists. Moreover, in this case $\lambda_{k}\left(t_{0}\right)=\alpha_{k}^{2}\left(t_{0}\right) \cdot \mu_{k}\left(t_{0}\right)$ holds.

Proof. First of all we are going to prove the case $t \searrow t_{0}$, i.e. we show that

$$
\lim _{t \searrow t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t_{0}}\right)-\operatorname{lmr}\left(f_{k, t_{0}, t_{0}}\right)}{t-t_{0}}=\alpha_{k}^{2}\left(t_{0}\right) \cdot \lim _{t \searrow t_{0}} \frac{\operatorname{lmr}\left(h_{k ; t}\right)-\operatorname{lmr}\left(h_{k ; t_{0}}\right)}{t-t_{0}} .
$$

Let be $t_{0} \in[0, T]$ and $k \in\{1, \ldots, m\}$. Since there is no risk of confusion we omit the index $k$.

Then we have with $G_{t, t_{0}}:=f_{t_{0}, t_{0}} \circ f_{t, t_{0}}^{-1}$,

$$
\begin{aligned}
\operatorname{lmr}\left(f_{t_{0}, t_{0}}\right)-\operatorname{lmr}\left(f_{t, t_{0}}\right) & =\log \left(\left.\frac{d}{d z} G_{t, t_{0}}(z)\right|_{z=0}\right)=\left.\log \left(\frac{G_{t, t_{0}}(z)}{z}\right)\right|_{z=0} \\
& =\frac{1}{2 \pi i} \int_{\partial D\left(t, t_{0}\right)} \log \left(\frac{G_{t, t_{0}}(\xi)}{\xi}\right) \frac{d \xi}{\xi} \\
& =\frac{1}{2 \pi} \int_{\partial D\left(t, t_{0}\right)} \log \left(\frac{G_{t, t_{0}}(\xi)}{\xi}\right) d \arg \xi \\
& =\frac{1}{2 \pi} \int_{\partial D\left(t, t_{0}\right)} \ln \left|\frac{G_{t, t_{0}}(\xi)}{\xi}\right| d \arg \xi
\end{aligned}
$$

as $\operatorname{lmr}(f)$ is a real quantity. $\left|G_{t, t_{0}}\right|$ is constant on each concentric slit, so we find

$$
\operatorname{lmr}\left(f_{t_{0}, t_{0}}\right)-\operatorname{lmr}\left(f_{t, t_{0}}\right)=\frac{1}{2 \pi} \int_{\partial \mathbb{D}} \ln \left|\frac{G_{t, t_{0}}(\xi)}{\xi}\right||d \xi|=\frac{1}{2 \pi} \int_{s_{t_{0}, t, t_{0}}} \ln \left|G_{t, t_{0}}(\xi)\right||d \xi|
$$

Next we set $H_{t, t_{0}}:=f_{t, t_{0}} \circ h_{t}^{-1}, F_{t, t_{0}}:=h_{t_{0}} \circ h_{t}^{-1}$ and $T_{t_{0}}:=f_{t_{0}, t_{0}} \circ h_{t_{0}}^{-1}$. Consequently we have by substitution, the mean value theorem and by using the relation $G_{t, t_{0}} \circ$ $H_{t, t_{0}}=T_{t_{0}} \circ F_{t, t_{0}}$

$$
\begin{aligned}
\operatorname{lmr}\left(f_{t_{0}, t_{0}}\right)-\operatorname{lmr}\left(f_{t, t_{0}}\right) & =\frac{1}{2 \pi} \int_{\sigma_{t_{0}, t}}\left|H_{t, t_{0}}^{\prime}(\zeta)\right| \cdot \ln \left|\left(G_{t, t_{0}} \circ H_{t, t_{0}}\right)(\zeta)\right||d \zeta| \\
& =\frac{1}{2 \pi}\left|H_{t, t_{0}}^{\prime}\left(\zeta_{t, t_{0}}\right)\right| \int_{\sigma_{t_{0}, t}} \ln \left|\left(T_{t_{0}} \circ F_{t, t_{0}}\right)(\zeta)\right||d \zeta|
\end{aligned}
$$

for some $\zeta_{t, t_{0}} \in \sigma_{t_{0}, t}$. Since $\zeta_{t, t_{0}} \rightarrow \zeta\left(t_{0}\right)$, we find $\left|H_{t, t_{0}}^{\prime}\left(\zeta_{t, t_{0}}\right)\right| \rightarrow \alpha\left(t_{0}\right)$ as $t \searrow t_{0}$ by Lemma 3.5.

Moreover, the function $\widetilde{T}_{t_{0}}(z):=\frac{1}{\xi\left(t_{0}\right)} \cdot T_{t_{0}}\left(\zeta\left(t_{0}\right) z\right)$ is a mapping that fulfills the conditions of Lemma 3.4, so we find for every $\delta>0$ an $\varepsilon>0$, so that

$$
|z|^{c+\delta} \leq\left|\widetilde{T}_{t_{0}}(z)\right| \leq|z|^{c-\delta}
$$

holds for all $z \in B_{\varepsilon}(1) \cap \mathbb{D}$, where $c=\widetilde{T}_{t_{0}}^{\prime}(1)>0$. Note that $c=\left|T_{t_{0}}^{\prime}\left(\zeta\left(t_{0}\right)\right)\right|=\alpha\left(t_{0}\right)$. As a consequence of $\left|\xi\left(t_{0}\right)\right|=\left|\zeta\left(t_{0}\right)\right|=1$ we get

$$
|z|^{c+\delta} \leq\left|T_{t_{0}}(z)\right| \leq|z|^{c-\delta}
$$

for all $z \in B_{\varepsilon}\left(\zeta\left(t_{0}\right)\right)$. On top of this, if $t$ is close enough to $t_{0}$ we get $F_{t, t_{0}}(\zeta) \in$ $B_{\varepsilon}\left(\zeta\left(t_{0}\right)\right)$ for all $\zeta \in \sigma_{t_{0}, t}$. Thus we have for all $t \in\left(t_{0}, t_{0}+\rho\right)$ where $\rho(\delta)>0$ is small

$$
\begin{aligned}
& \frac{1}{2 \pi}\left|H_{t, t_{0}}^{\prime}\left(\zeta_{t, t_{0}}\right)\right|\left(\alpha\left(t_{0}\right)+\delta\right) \int_{\sigma_{t_{0}, t}} \ln \left|F_{t, t_{0}}(\zeta)\right||d \zeta| \\
& \quad \leq \operatorname{lmr}\left(f_{t_{0}, t_{0}}\right)-\operatorname{lmr}\left(f_{t, t_{0}}\right) \leq \frac{1}{2 \pi}\left|H_{t, t_{0}}^{\prime}\left(\zeta_{t, t_{0}}\right)\right|\left(\alpha\left(t_{0}\right)-\delta\right) \int_{\sigma_{t_{0}, t}} \ln \left|F_{t, t_{0}}(\zeta)\right||d \zeta| .
\end{aligned}
$$

Moreover in the same way as before we can see that

$$
\frac{1}{2 \pi} \int_{\sigma_{t_{0}, t}} \ln \left|F_{t, t_{0}}(\zeta)\right||d \zeta|=\operatorname{lmr}\left(h_{t_{0}}\right)-\operatorname{lmr}\left(h_{t}\right)
$$

By combining this with the previous inequality we get for all $t \in\left(t_{0}, t_{0}+\rho\right)$,

$$
\left|H_{t, t_{0}}^{\prime}\left(\zeta_{t, t_{0}}\right)\right|\left(\alpha\left(t_{0}\right)-\delta\right) \leq \frac{\operatorname{lmr}\left(f_{t_{0}, t_{0}}\right)-\operatorname{lmr}\left(f_{t, t_{0}}\right)}{\operatorname{lmr}\left(h_{t_{0}}\right)-\operatorname{lmr}\left(h_{t}\right)} \leq\left|H_{t, t_{0}}^{\prime}\left(\zeta_{t, t_{0}}\right)\right|\left(\alpha\left(t_{0}\right)+\delta\right)
$$

As $\delta>0$ is arbitrary, we get in the limit case the existence of $\lambda\left(t_{0}\right)$ if and only if $\mu\left(t_{0}\right)$ exists. Moreover we find

$$
\lambda\left(t_{0}\right)=\alpha\left(t_{0}\right)^{2} \cdot \mu\left(t_{0}\right)
$$

as $\left|H_{t, t_{0}}^{\prime}\left(\zeta_{t, t_{0}}\right)\right|$ tends to $\alpha\left(t_{0}\right)$ by Lemma 3.5, so the proof is complete.
The other case $t \nearrow t_{0}$, i.e.

$$
\lim _{t / t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t_{0}}\right)-\operatorname{lmr}\left(f_{k ; t_{0}, t_{0}}\right)}{t-t_{0}}=\alpha_{k}^{2}\left(t_{0}\right) \cdot \lim _{t \backslash t_{0}} \frac{\operatorname{lmr}\left(h_{k ; t}\right)-\operatorname{lmr}\left(h_{k ; t_{0}}\right)}{t-t_{0}}
$$

follows in the same way.

Lemma 3.7. Let $\Omega$ be simply connected, i.e. $\Omega=\mathbb{D}$. Then $\alpha_{k}(t) \leq 1$ for all $t \in[0, T]$.

Proof. First, let $0 \leq \underline{t}<\bar{t} \leq T, \quad 0 \leq \underline{\tau}<\bar{\tau} \leq T \quad$ and $\quad A:=f_{k ; \underline{t}, \underline{\tau}}\left(\gamma_{k}[\underline{t}, \bar{t}]\right), \quad B:=$ $f_{k ; t, \tau}\left(\bigcup_{j \neq k} \gamma_{j}[\underline{\tau}, \bar{\tau}]\right)$. By using the chain rule we get

$$
\begin{aligned}
\operatorname{lmr}(A) & =\operatorname{lmr}\left(f_{k ; \bar{t}, \underline{\tau}}\right)-\operatorname{lmr}\left(f_{k ; t, \mathcal{\tau}}\right), \quad \operatorname{lmr}(B)=\operatorname{lmr}\left(f_{k ; t, \bar{\tau}}\right)-\operatorname{lmr}\left(f_{k ; t, \tau}\right) \quad \text { and } \\
\operatorname{lmr}(A \cup B) & =\operatorname{lmr}\left(f_{k ; \bar{\tau}, \bar{\tau}}\right)-\operatorname{lmr}\left(f_{k ; t, \mathcal{\tau}}\right) .
\end{aligned}
$$

Furthermore, as $\Omega$ is simply connected, we have the following inequality (see [12]):

$$
\operatorname{lmr}(A \cup B) \leq \operatorname{lm}(A)+\operatorname{lmr}(B)
$$

By combining this inequality with the previous equations we obtain

$$
\begin{equation*}
\operatorname{lmr}\left(f_{k ; \bar{\tau}, \bar{\tau}}\right)-\operatorname{lmr}\left(f_{k ; t, \bar{\tau}}\right) \leq \operatorname{lmr}\left(f_{k ; \bar{t}, \mathcal{\tau}}\right)-\operatorname{lmr}\left(f_{k ; ;, \tau}\right) \tag{7}
\end{equation*}
$$

Next we find together with Lemma 3.6

$$
\alpha_{k}^{2}\left(t_{0}\right)=\lim _{t \rightarrow t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t_{0}}\right)-\operatorname{lmr}\left(f_{k ; t_{0}, t_{0}}\right)}{\operatorname{lmr}\left(h_{k ; t}\right)-\operatorname{lmr}\left(h_{k ; t_{0}}\right)}=\lim _{t \backslash t_{0}} \frac{\operatorname{lmr}\left(f_{k ; t, t_{0}}\right)-\operatorname{lmr}\left(f_{k ; t_{0}, t_{0}}\right)}{\operatorname{lmr}\left(f_{k ; t, 0}\right)-\operatorname{lmr}\left(f_{k ; t_{0}, 0}\right)} \leq 1 .
$$

Proof of Theorem 1.12. This follows immediately from Lemmas 3.1, 3.2, 3.5 and 3.6.

## Proof of Proposition 2.4.

(1) First, we find a unique continuous function $v_{2}:[0, L] \rightarrow[0, T]$ so that $\operatorname{lmr}\left(\tilde{g}_{s}\right)$ $=s$ since $\operatorname{lmr}\left(h_{1, v_{1}(s)}\right)=u_{1}(s) \leq K s<s$. Note that the continuity is an immediate consequence of Proposition 7 from [2]. Consequently it remains to prove that $v_{2}$ is bijective. First we note that it is clear that $v_{2}([0, L])=[0, T]$, so it remains to show that $v_{2}$ is injective.

Let $0 \leq s_{1}<s_{2} \leq L$ and assume $v_{2}\left(s_{1}\right)=v_{2}\left(s_{2}\right)$. We denote by $f_{t, \tau}: \mathbb{D} \backslash\left(\gamma_{1}[0, t] \cup\right.$ $\left.\gamma_{2}[0, \tau]\right) \rightarrow \mathbb{D}$ the normalized Riemann map from $\Omega \backslash\left(\gamma_{1}[0, t] \cup \gamma_{2}[0, \tau]\right)$ onto $\mathbb{D}$. By using (7) with $\underline{t}:=v_{1}\left(s_{1}\right), \bar{t}:=v_{1}\left(s_{2}\right), \underline{\tau}:=v_{2}\left(s_{1}\right)$ and $\bar{\tau}:=v_{2}\left(s_{2}\right)$ we obtain

$$
\begin{aligned}
s_{2}-s_{1} & =\operatorname{lmr}\left(f_{\bar{t}, \bar{\tau}}\right)-\operatorname{lmr}\left(f_{\underline{t}, \underline{\underline{\tau}}}\right)=\operatorname{lmr}\left(f_{\overline{\bar{t}, \underline{\tau}}}\right)-\operatorname{lmr}\left(f_{\underline{t}, \underline{\tau}}\right) \\
& \leq \operatorname{lmr}\left(f_{\bar{t}, 0}\right)-\operatorname{lmr}\left(f_{\underline{t}, 0}\right)=\operatorname{lmr}\left(h_{1 ; \bar{t}}\right)-\operatorname{lmr}\left(h_{1 ; \underline{\underline{t}}}\right)<s_{2}-s_{1} .
\end{aligned}
$$

This is a contradiction, so $v_{2}$ needs to be bijective. Note that this argumentation does not use the fact that $\gamma_{1}(0) \neq \gamma_{2}(0)$.
(2) Now we suppose that $u_{1}$ is continuously differentiable and prove that (4) holds. First we set $\widetilde{\gamma}_{1}(s):=\left(\gamma_{1} \circ v_{1}\right)(s), \widetilde{\gamma}_{2}(s):=\left(\gamma_{2} \circ v_{2}\right)(s)$ and denote by $\tilde{f}_{s_{1}, s_{2}}: \mathbb{D} \backslash$ $\left(\widetilde{\gamma}_{1}\left[0, s_{1}\right] \cup \widetilde{\gamma}_{2}\left[0, s_{2}\right]\right) \rightarrow \mathbb{D}$ the normalized Riemann map from $\mathbb{D} \backslash\left(\widetilde{\gamma}_{1}\left[0, s_{1}\right] \cup \widetilde{\gamma}_{2}\left[0, s_{2}\right]\right)$ onto $\mathbb{D}$. Let be $Z=\left\{0, \ldots, s_{N}\right\}$ a partition of the interval $[0, s]$ and

$$
\begin{aligned}
& S_{1}(s, Z):=\sum_{l=0}^{N-1} \operatorname{lmr}\left(\tilde{f}_{s_{l+1}, s_{l}}\right)-\operatorname{lmr}\left(\tilde{f}_{s_{l}, s_{l}}\right) \quad \text { and } \\
& S_{2}(s, Z):=\sum_{l=0}^{N-1} \operatorname{lmr}\left(\tilde{f}_{s_{l}, s_{l+1}}\right)-\operatorname{lmr}\left(\tilde{f}_{s_{l}, s_{l}}\right)
\end{aligned}
$$

Since $\operatorname{lmr}\left(\tilde{g}_{s}\right)=s$ for all $s \in[0, L]$, by Proposition 17 from [2] the limits $c_{k}(s):=$ $\lim _{|Z| \rightarrow 0} S_{k}(s, Z)$ exist and form increasing and Lipschitz continuous functions $s \mapsto$ $c_{k}(s)$, with $c_{1}(s)+c_{2}(s)=s$ for all $s \in[0, L]$. On the one hand, again by Proposition 17 from [2], the limits

$$
\tilde{\lambda}_{k}(s)=\lim _{t \rightarrow s} \frac{\operatorname{lmr}\left(\tilde{f}_{k ; t, s}\right)-\operatorname{lmr}\left(\tilde{f}_{k ; s, s}\right)}{t-s}
$$

exist and coincide with $\dot{c}_{k}(s)$ for every point $s \in[0, L]$ at which $c_{k}$ is differentiable. On the other hand, according to Lemmas 3.5 and 3.6, the continuous differentiability of $u_{1}$ implies that $s \mapsto \tilde{\lambda}_{1}(s)$ is continuous on $[0, L]$. Therefore, $c_{1}$ and hence $c_{2}(s)=$ $s-c_{1}(s)$ are, in fact, continuously differentiable. It follows that $s \mapsto \tilde{\lambda}_{2}(s)$ is also continuous and that $\tilde{\lambda}_{1}(s)+\tilde{\lambda}_{2}(s)=1$ for all $s \in[0, L]$. Now it remains to apply Theorem 2 from [2] to conclude that $\tilde{g}_{s}$ satisfies equation (4) for all $s \in[0, L]$.

## 4. Proof of Theorems 1.3 and 1.5

In this section we prove Theorems 1.3 and 1.5. We will use a different setting, namely the upper half-plane and the chordal Loewner equation, instead of the radial case in the unit disk. Here, the role of the logarithmic mapping radius is played by the so called half-plane capacity, which has nicer properties for our purpose. First, we describe the chordal Loewner equation and prove the chordal analogs of Theorems 1.3 and 1.5. At the end of this chapter we justify why it makes sense to consider this different setting.

Denote by $\mathbb{H}:=\{z \in \mathbb{C} \mid \operatorname{Im}(z)>0\}$ the upper half-plane. A bounded subset $A \subset \mathbb{H}$ is called a (compact) hull if $A=\mathbb{H} \cap \bar{A}$ and $\mathbb{H} \backslash A$ is simply connected. By $g_{A}$ we denote the unique conformal mapping from $\mathbb{H} \backslash A$ onto $\mathbb{H}$ with hydrodynamic normalization, i.e.

$$
\begin{equation*}
g_{A}(z)=z+\frac{b}{z}+\mathcal{O}\left(|z|^{-2}\right) \quad \text { for }|z| \rightarrow \infty \tag{8}
\end{equation*}
$$

and for some $b \geq 0$. The quantity hcap $(A):=b$ is called half-plane capacity of $A$. We note four important properties of hcap; see [7], p. 69 and p. 71.

## Lemma 4.1.

(a) $\operatorname{hcap}(c \cdot A)=c^{2} \cdot \operatorname{hcap}(A)$ for every $c>0$ and every hull $A$.
(b) If $A_{1}, A_{2}$ are two hulls such that $A_{1} \cup A_{2}$ is also a hull, then

$$
\operatorname{hcap}\left(A_{1} \cup A_{2}\right) \leq \operatorname{hcap}\left(A_{1}\right)+\operatorname{hcap}\left(A_{2}\right)
$$

This inequality is strict if both hulls are nonempty.
(c) If $A_{1}, A_{2}$ are two hulls such that $A_{1} \cup A_{2}$ is a hull as well, then $\operatorname{hcap}\left(A_{1}\right) \geq$ $\operatorname{hcap}\left(g_{A_{2}}\left(A_{1}\right)\right)$. If both hulls are nonempty, then the inequality is strict.
(d) If $A_{1}, A_{2}$ are hulls with $A_{1} \subset A_{2}$, then $\operatorname{hcap}\left(A_{2}\right)-\operatorname{hcap}\left(A_{1}\right)=\operatorname{hcap}\left(g_{A_{1}}\left(A_{2} \backslash\right.\right.$ $\left.A_{1}\right)$ ).

If $\gamma:[0, T] \rightarrow \overline{\mathbb{H}}$ is a simple curve, i.e. a continuous, one-to-one function with $\gamma(0) \in \mathbb{R}$ and $\gamma((0, T]) \subset \mathbb{H}$, then we call the hull $\Gamma:=\gamma((0, T])$ a slit. If the function $t \mapsto b(t):=\operatorname{hcap}(\gamma((0, t]))$ is differentiable at $t_{0}$, then the family $g_{t}:=g_{\gamma(0, t]}, 0 \leq t \leq T$, satisfies the following chordal Loewner equation (see [7], Chapter 5):

$$
\begin{equation*}
\dot{g}_{t_{0}}(z)=\frac{\dot{b}\left(t_{0}\right)}{g_{t_{0}}(z)-U\left(t_{0}\right)} \tag{9}
\end{equation*}
$$

where $U\left(t_{0}\right)=g_{t_{0}}\left(\gamma\left(t_{0}\right)\right)$.
$\gamma$ is called half-plane parametrization of $\Gamma$ if hcap $(\gamma(0, t])=t$ for all $t \in[0, T] .\left(^{1}\right)$
Furthermore, we will need the following definition:
Let $\varphi \in(0, \pi)$. We say that $\Gamma$ approaches $\mathbb{R}$ at $x \in \mathbb{R}$ in $\varphi$-direction if for every $\varepsilon>0$ there is a $t_{0}>0$ such that $\gamma\left(0, t_{0}\right]$ is contained in the set $\{z \in \mathbb{H} \mid \varphi-\varepsilon<$ $\arg (z-x)<\varphi+\varepsilon\}$.

We will need the following lemma about half-plane capacities of straight line segments.

Lemma 4.2. Let $b_{1}, b_{2}>0$ and let $\Gamma_{1}, \Gamma_{2}$ be two line segments starting at 0 with angles $\alpha_{1}, \alpha_{2} \in(0, \pi), \alpha_{1}<\alpha_{2}$, and hcap $\left(\Gamma_{1}\right)=b_{1}, \operatorname{hcap}\left(\Gamma_{2}\right)=b_{2}$. Then

$$
\operatorname{hcap}\left(\Gamma_{1} \cup \Gamma_{2}\right) \rightarrow b_{1}+b_{2}
$$

as $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$.

Proof. Let $\gamma_{j}:\left[0, b_{j}\right] \rightarrow \Gamma_{j}$ be the half-plane parametrization of $\Gamma_{j}$, i.e. $\operatorname{hcap}\left(\gamma_{j}(0, t]\right)=t$.

We will use a formula which translates the half-plane capacity of an arbitrary hull $A$ into an expected value of a random variable derived from a Brownian motion hitting this hull. Let $B_{s}$ be a Brownian motion started in $z \in \mathbb{H} \backslash A$. We write $\mathbf{P}^{z}$ and $\mathbf{E}^{z}$ for probabilities and expectations derived from $B_{s}$. Let $\tau_{A}$ be the smallest time $s$ with $B_{s} \in \mathbb{R} \cup A$. Then formula (3.6) of Proposition 3.41 in [7] tells us

$$
\operatorname{hcap}(A)=\lim _{y \rightarrow \infty} y \mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\tau_{A}}\right)\right] .
$$

Let $\varrho=\tau_{\Gamma_{1}}$ and $\sigma=\tau_{\Gamma_{2}}$. Then we have (compare with the proof of Proposition 3.42 in [7])

$$
\begin{aligned}
\operatorname{hcap}\left(\Gamma_{1}\right)+\operatorname{hcap}\left(\Gamma_{2}\right)-\operatorname{hcap}\left(\Gamma_{1} \cup\right. & \left.\Gamma_{2}\right) \\
& =\lim _{y \rightarrow \infty} y\left(\mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho\right]+\mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\varrho}\right) ; \sigma<\varrho\right]\right) .
\end{aligned}
$$

Here we use the notation $\mathbf{E}^{z}[X ; A]:=\mathbf{E}^{z}\left[X \mathbf{1}_{A}\right]$, where $X$ is a random variable and $\mathbf{1}_{A}$ is the indicator function of the event $A$.

In the following we will estimate the term $\mathbf{E}^{y i}\left[\left(B_{\sigma}\right) ; \sigma>\varrho\right]$, assuming that $y$ is so large that $y i$ is not contained in the union of the two slits.

[^0]First we note that $\gamma_{j}(1)$ and $\operatorname{Im}\left(\gamma_{j}(1)\right)$ can be computed explicitly; see Example 3.39 in [7]:

$$
\begin{equation*}
\gamma_{j}(1)=\sqrt{2} \cdot\left(\sqrt{\alpha_{j} / \pi}\right)^{2 \alpha_{j} / \pi-1} \cdot\left(\sqrt{1-\alpha_{j} / \pi}\right)^{1-2 \alpha_{j} / \pi} e^{i \alpha_{j}} \cdot \sqrt{b_{j}} \tag{10}
\end{equation*}
$$

and consequently

$$
\operatorname{Im}\left(\gamma_{1}(1)\right)=\sin \left(\alpha_{j}\right) \cdot \sqrt{2} \cdot\left(\sqrt{\alpha_{j} / \pi}\right)^{2 \alpha_{j} / \pi-1} \cdot\left(\sqrt{1-\alpha_{j} / \pi}\right)^{1-2 \alpha_{j} / \pi} \cdot \sqrt{b_{j}}
$$

Note that $\operatorname{Im}\left(\gamma_{j}(1)\right) \rightarrow 0$ and $\left|\gamma_{j}(1)\right| \rightarrow \infty$ as $\alpha_{j} \rightarrow 0$ or $\alpha_{j} \rightarrow \pi$.
Let $R>0$ and assume that $\alpha_{1}$ is so close to 0 that $\operatorname{Im}\left(\gamma_{1}(1)\right)<R$ and

$$
\begin{equation*}
\left|\gamma_{1}(1)\right|>R \tag{*}
\end{equation*}
$$

and write

$$
\mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho\right]=\mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho \wedge\left|B_{\varrho}\right|<R\right]+\mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho \wedge\left|B_{\varrho}\right| \geq R\right] .
$$

The first summand: We have $\mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho \wedge\left|B_{\varrho}\right|<R\right] \leq \operatorname{Im}\left(\gamma_{2}(1)\right) \cdot \mathrm{P}\left\{B_{\varrho} \in\right.$ $\left.\Gamma_{1} \cap\{|z|<R\}\right\}$. Now we use that the limit $\lim _{y \rightarrow \infty} y \mathbf{P}\left\{B_{\varrho} \in \Gamma_{1} \cap\{|z|<R\}\right\}$ exists; see [7], p. 74; and that there exists a universal constant $c_{2}$ such that

$$
\lim _{y \rightarrow \infty} y \mathbf{P}\left\{B_{\varrho} \in \Gamma_{1} \cap\{|z|<R\}\right\} \leq c_{2} \operatorname{diam}\left(\Gamma_{1} \cap\{|z|<R\}\right)=c_{2} \cdot R
$$

see [7], p. 74. Thus we get

$$
\lim _{y \rightarrow \infty} y \mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho \wedge\left|B_{\varrho}\right|<R\right] \leq c_{2} R \cdot \operatorname{Im}\left(\gamma_{2}(1)\right) \rightarrow 0 \quad \text { as }\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)
$$

The second summand: First we have $\mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho \wedge\left|B_{\varrho}\right| \geq R\right] \leq \operatorname{Im}\left(\gamma_{2}(1)\right)$. $\mathbf{P}^{y i}\left\{B_{\sigma} \in \Gamma_{2} ; \sigma>\varrho \wedge\left|B_{\varrho}\right| \geq R\right\}$.

A Brownian motion satisfying $\sigma>\varrho \wedge\left|B_{\varrho}\right| \geq R$ will hit $\Gamma_{1}$ at a point $Q$ with $|Q| \geq R$ and afterward it has to hit $\Gamma_{2}$ without hitting the real axis. Call the probability of this event $p_{Q}$.

From (*) it follows that the Brownian motion hitting $Q$ has to leave the half-disk $\{z \in \mathbb{H} \cup \mathbb{R}||z-\operatorname{Re}(Q)|<R\}$ without hitting the real axis; see Figure 3. From Beurling's estimate (Theorem 3.76 in [7]) it follows that $p_{Q} \leq c_{1} \cdot \operatorname{Im}(Q) \leq$ $c_{1} \cdot \operatorname{Im}\left(\gamma_{1}(1)\right) .\left({ }^{2}\right)$ So we get

$$
\mathbf{P}^{y i}\left\{B_{\sigma} \in \Gamma_{2} ; \sigma>\varrho \wedge\left|B_{\sigma}\right| \geq R\right\} \leq \mathbf{P}^{y i}\left\{B_{\sigma} \in \Gamma_{2}\right\} \cdot c_{1} \cdot \operatorname{Im}\left(\gamma_{1}(1)\right) .
$$

$\left(^{2}\right)$ Note that Theorem 3.76 in [7] gives an estimate on the probability that a Brownian motion started in $\mathbb{D}$ will not have hit a fixed curve, say $[0,1]$, when leaving $\mathbb{D}$ for the first time. The estimate we use can be simply recovered by mapping the half-circle $\mathbb{D} \cap \mathbb{H}$ conformally onto $\mathbb{D} \backslash[0,1]$ by $z \mapsto z^{2}$.

Figure 3. A Brownian motion with $\sigma>\varrho$ and $\left|B_{\varrho}\right| \geq R$.

Again we have $\lim _{y \rightarrow \infty} y \mathbf{P}^{y i}\left\{B_{\sigma} \in \Gamma_{2}\right\} \leq c_{2} \operatorname{diam}\left(\Gamma_{2}\right)=c_{2} \cdot\left|\gamma_{2}(1)\right|$.
Thus, using (10), we have

$$
\begin{aligned}
\lim _{y \rightarrow \infty} y \mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ;\right. & \left.\sigma>\varrho\left|B_{\varrho}\right| \geq R\right] \\
& \leq \operatorname{Im}\left(\gamma_{2}(1)\right) \cdot c_{2} \cdot\left|\gamma_{2}(1)\right| \cdot c_{1} \cdot \operatorname{Im}\left(\gamma_{1}(1)\right) \\
& =c_{1} c_{2} \operatorname{Im}\left(\gamma_{1}(1)\right) \sin \left(\alpha_{2}\right) \cdot\left|\gamma_{2}(1)\right|^{2} \\
& =2 c_{1} c_{2} b_{1} \cdot \operatorname{Im}\left(\gamma_{1}(1)\right) \cdot \sin \left(\alpha_{2}\right) \cdot\left(1-\alpha_{2} / \pi\right)^{1-2 \alpha_{2} / \pi} \cdot\left(\alpha_{2} / \pi\right)^{2 \alpha_{2} / \pi-1}
\end{aligned}
$$

Note that

$$
\operatorname{Im}\left(\gamma_{1}(1)\right) \rightarrow 0, \quad \sin \left(\alpha_{2}\right) \cdot\left(1-\alpha_{2} / \pi\right)^{1-2 \alpha_{2} / \pi} \rightarrow \pi \quad \text { and } \quad\left(\alpha_{2} / \pi\right)^{2 \alpha_{2} / \pi-1} \rightarrow 1
$$

and consequently $\lim _{y \rightarrow \infty} y \mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\sigma}\right) ; \sigma>\varrho \wedge\left|B_{\varrho}\right| \geq R\right] \rightarrow 0$ as $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$.
In the same way we obtain $\lim _{y \rightarrow \infty} y \mathbf{E}^{y i}\left[\operatorname{Im}\left(B_{\varrho}\right) ; \sigma<\varrho\right] \rightarrow 0$ as $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$ and thus

$$
\operatorname{hcap}\left(\Gamma_{1} \cup \Gamma_{2}\right) \rightarrow \operatorname{hcap}\left(\Gamma_{1}\right)+\operatorname{hcap}\left(\Gamma_{2}\right) \quad \text { as }\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)
$$

Let $\Gamma_{1}, \Gamma_{2}$ be two slits with parametrizations $\gamma_{1}$ and $\gamma_{2}$. Furthermore, we let $h_{1}(t):=\operatorname{hcap}\left(\gamma_{1}(0, t]\right), h_{2}(t):=\operatorname{hcap}\left(\gamma_{2}(0, t]\right)$ and $c(t):=\operatorname{hcap}\left(\gamma_{1}(0, t] \cup \gamma_{2}(0, t]\right)$.

Theorem 4.3. Let $b_{1}, b_{2} \geq 0$ and let $\Gamma_{1}, \Gamma_{2}$ be two slits with $\overline{\Gamma_{1}} \cap \overline{\Gamma_{2}}=\{p\} \subset \mathbb{R}$, such that $\Gamma_{j}$ approaches $p$ in $\alpha_{j}$-direction for $j=1,2$, with $0<\alpha_{1} \leq \alpha_{2}<\pi$. Assume that $h_{1}(t)$ and $h_{2}(t)$ are differentiable for $t=0$ with $b_{1}=\dot{h}_{1}(0), b_{2}=\dot{h}_{2}(0)$. Then $c(t)$ is differentiable at $t=0$.
(i) If $b_{1}=0$ or $b_{2}=0$, then $\dot{c}(0)=\max \left\{b_{1}, b_{2}\right\}$.

If $b_{1}, b_{2}>0$, then
(ii) $\max \left\{b_{1}, b_{2}\right\} \leq \dot{c}(0)<b_{1}+b_{2}$,
(iii) $\dot{c}(0)=\max \left\{b_{1}, b_{2}\right\}$ if and only if $\alpha_{1}=\alpha_{2}$ and
(iv) $\dot{c}(0) \rightarrow b_{1}+b_{2}$ as $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$.

Proof. By translation we can assume that $p=0$.
For $t>0$, we define $G_{t}=\left(\gamma_{1}(0, t] \cup \gamma_{2}(0, t]\right) / \sqrt{t}$. By Lemma 4.1(a) we have

$$
c(t) / t=\operatorname{hcap}\left(\gamma_{1}[0, t] / \sqrt{t} \cup \gamma_{1}[0, t] / \sqrt{t}\right)=\operatorname{hcap}\left(G_{t}\right)
$$

First, we assume that $\Gamma_{1}$ and $\Gamma_{2}$ are straight line segments. Since hcap $\left(\gamma_{j}[0, t] /\right.$ $\sqrt{t})=h_{j}(t) / t \rightarrow \dot{h}_{j}(0)$ as $t \rightarrow 0$ for $j=1,2$, we conclude that the tip of the line segment $\gamma_{j}[0, t] / \sqrt{t}$ converges to the tip of the line segment $L_{j}$ with the same angle and halfplane capacity $\dot{h}_{j}(0)=b_{j}=\operatorname{hcap}\left(L_{j}\right)$.

From [9], Lemma 4.10, it follows that hcap $\left(G_{t}\right) \rightarrow \operatorname{hcap}\left(L_{1} \cup L_{2}\right)$ as $t \rightarrow 0$. Consequently, $c(t)$ is differentiable at $t=0$ with $\dot{c}(0)=\operatorname{hcap}\left(L_{1} \cup L_{2}\right)$.

If $\operatorname{hcap}\left(L_{1}\right)=0$ or $\operatorname{hcap}\left(L_{2}\right)=0$, then hcap $\left(L_{1} \cup L_{2}\right)=\max \left\{\operatorname{hcap}\left(L_{1}\right), \operatorname{hcap}\left(L_{2}\right)\right\}$. This proves (i).

If, on the other hand, $\operatorname{hcap}\left(L_{1}\right), \operatorname{hcap}\left(L_{2}\right)>0$, then Lemma 4.1(b) gives

$$
\max \left\{\operatorname{hcap}\left(L_{1}\right), \operatorname{hcap}\left(L_{2}\right)\right\} \leq \operatorname{hcap}\left(L_{1} \cup L_{2}\right)<\operatorname{hcap}\left(L_{1}\right)+\operatorname{hcap}\left(L_{2}\right),
$$

hence $\max \left\{b_{1}, b_{2}\right\} \leq \dot{c}(0)<b_{1}+b_{2}$.
We have $\dot{c}(0)=b_{j}$ if and only if $\operatorname{hcap}\left(L_{j}\right)=\operatorname{hcap}\left(L_{1} \cup L_{2}\right)$, i.e. $L_{j}=L_{1} \cup L_{2}$ which is equivalent to $\alpha_{1}=\alpha_{2}$ and $\operatorname{hcap}\left(L_{j}\right) \geq \operatorname{hcap}\left(L_{3-j}\right)$.

Since $\operatorname{hcap}\left(L_{1} \cup L_{2}\right) \rightarrow \operatorname{hcap}\left(L_{1}\right)+\operatorname{hcap}\left(L_{2}\right)$ as $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$ by Lemma 4.2, we get $\dot{c}(0) \rightarrow b_{1}+b_{2}$ as $\left(\alpha_{1}, \alpha_{2}\right) \rightarrow(0, \pi)$. Thus, we have shown all statements of the theorem for the case of two line segments.

Now we pass on to the general case.
For $j=1,2$ let $L_{j}$ be the straight line segment starting at 0 with angle $\alpha_{j}$ and $\operatorname{hcap}\left(L_{j}\right)=b_{j}$.

Since $\Gamma_{j}$ approaches 0 in $\alpha_{j}$-direction, we have $\mathbb{H} \backslash\left(\gamma_{j}[0, t] / \sqrt{t}\right) \rightarrow \mathbb{H} \backslash L_{j}$ as $t \rightarrow 0$ in the sense of kernel convergence w.r.t. the point $\infty$. $\left(^{3}\right)$

From this it follows that $\mathbb{H} \backslash G_{t} \rightarrow \mathbb{H} \backslash\left(L_{1} \cup L_{2}\right)$ as $t \rightarrow 0$ and, by the definition of hcap [see (8)] and the Carathéodory Kernel Convergence Theorem, we obtain

$$
\operatorname{hcap}\left(G_{t}\right) \rightarrow \operatorname{hcap}\left(L_{1} \cup L_{2}\right) \quad \text { as } t \rightarrow 0
$$

Hence $c(t)$ is differentiable at $t=0$ with $\dot{c}(0)=\operatorname{hcap}\left(L_{1} \cup L_{2}\right)$.

[^1]Thus, by using the case of two line segments, we immediately get the statements (i), (ii), (iii) and (iv).

Theorem 4.4. There exist two slits $\Gamma_{1}, \Gamma_{2}$, with $\overline{\Gamma_{1}} \cap \overline{\Gamma_{2}}=\{0\}$, such that $h_{j}(t)=$ $t$ for all $t \in\left[0, \operatorname{hcap}\left(\Gamma_{j}\right)\right]$, but $c(t)$ is not differentiable at $t=0$.

Proof. Assume that $\Gamma$ is a slit starting at 0 with half-plane parametrization $\gamma:(0, T] \rightarrow \mathbb{C}$ having the property $\Gamma \subset\{z \in \mathbb{H} \mid \operatorname{Re}(z)>0\}$ and assume further that $\Gamma$ is self-similar in the following sense:

$$
1 / 2 \cdot \Gamma \subset \Gamma
$$

Lemma 4.1(a) implies that $\gamma\left(0,1 / 4^{n} \cdot T\right]=1 / 2^{n} \cdot \Gamma$ for every $n \in \mathbb{N}$.
Now let $\Gamma^{*}$ be the reflection of $\Gamma$ with respect to the imaginary axis, i.e. $\Gamma^{*}:=$ $\{-\bar{z} \mid z \in \Gamma\}$. Denote by $\gamma^{*}$ the half-plane parametrization of $\Gamma^{*}$ and let $K_{t}=\gamma(0, t] \cup$ $\gamma^{*}(0, t]$.

Then also $K_{1}$ is self-similar, i.e. $1 / 2 \cdot K_{t} \subset K_{t}$ and thus for any $t \in[0, T]$ the half-plane capacity $c(t):=\operatorname{hcap}\left(K_{t}\right)$ of the hull $K_{t}$ satisfies $c(t / 4)=c(t) / 4$ and consequently

$$
\frac{c\left(t / 4^{n}\right)}{t / 4^{n}}=\frac{c(t)}{t}
$$

for every $n \in \mathbb{N}$. Hence, if we assume that $c(t)$ is differentiable at $t=0$, then $c(t)$ is linear with $c(t)=\dot{c}(0) \cdot t$.

Below we construct such a self-similar slit $\Gamma$ having the property that $c(t)$ is not linear, which gives us the desired contradiction.

Let $0 \leq \varepsilon<1 / 2$ and let $A$ be the curve that connects the points $3 / 4 i+\varepsilon / 2, i+\varepsilon$, $1 / 2+i, 1 / 2+3 / 2 i$ and $3 / 2 i+\varepsilon$ by straight line segments. Note that $A$ and $1 / 2 \cdot A$ intersect only at $3 / 4 i+\varepsilon / 2$.

Now we define the slit

$$
\Gamma:=\bigcup_{n=0}^{\infty} 1 / 2^{n} \cdot A
$$

see Figure 4. Of course, this slit is self-similar, i.e.

$$
1 / 2 \cdot \Gamma \subset \Gamma
$$

Let $\Gamma^{*}$ be the reflection of $\Gamma$ w.r.t. the imaginary axis. Now let $\gamma, \gamma^{*}:(0, T] \rightarrow \mathbb{C}$ be the parametrizations of $\Gamma$ and $\Gamma^{*}$ by half-plane capacity.

For each $t \in(0, T]$ we can define $K_{t}$ as the smallest hull containing $\gamma(0, t] \cup$ $\gamma^{*}(0, t]$. Note that $K_{t}=\gamma(0, t] \cup \gamma^{*}(0, t]$ for $\varepsilon>0$. Only for $\varepsilon=0$, the complement of the union has bounded components. Let $c(t):=\operatorname{hcap}\left(K_{t}\right)$ and let $t_{2}$ and $t_{1}$ be defined by $\gamma\left(t_{1}\right)=3 / 4 i+\varepsilon / 2$ and $\gamma\left(t_{2}\right)=i+\varepsilon$.

Figure 4. $A$ and $\Gamma$ for $\varepsilon=0$.

The quantities $t_{2}, t_{1}, c\left(t_{2}\right), c\left(t_{1}\right)$ depend continuously on $\varepsilon$, as the domains $\mathbb{H} \backslash$ $\gamma(0, t], \mathbb{H} \backslash K_{t}$ depend continuously on $\varepsilon$ w.r.t. kernel convergence at $\infty$ (see the proof of Theorem 4.3).

For $\varepsilon=0$ we have $K_{t_{2}} \backslash K_{t_{1}}=\gamma\left(t_{1}, t_{2}\right]$ and we obtain

$$
\begin{aligned}
& t_{2}-t_{1} \underset{\text { Lemma 4.1(d) }}{=} \operatorname{hcap}\left(g_{\gamma\left(0, t_{1}\right]}\left(\gamma\left(t_{1}, t_{2}\right]\right)\right) \underset{\text { Lemma 4.1(c) }}{>} \operatorname{hcap}\left(g_{K_{t_{1}}}\left(\gamma\left(t_{1}, t_{2}\right]\right)\right) \\
& \quad=c\left(t_{2}\right)-c\left(t_{1}\right)
\end{aligned}
$$

Here, we apply Lemma 4.1(c) for $A_{1}=g_{\gamma\left(0, t_{1}\right]}\left(\gamma\left(t_{1}, t_{2}\right]\right)$ and $A_{2}=g_{\gamma\left(0, t_{1}\right]}\left(K_{t_{1}} \backslash\right.$ $\left.\gamma\left(0, t_{1}\right]\right)$. Note that $g_{K_{t_{1}}}=g_{A_{2}} \circ g_{\gamma\left(0, t_{1}\right]}$.

Now choose an $\varepsilon>0$ so small that we still have

$$
\begin{equation*}
\frac{c\left(t_{2}\right)-c\left(t_{1}\right)}{t_{2}-t_{1}}<1 \tag{11}
\end{equation*}
$$

Assume $c(t)$ is differentiable at $t=0$ in this case. Then $c$ is linear as we have seen before. As $T=\operatorname{hcap}(\Gamma)<c(T)=\dot{c}(0) \cdot$ hcap $(\Gamma)$, we have $\dot{c}(0)>1$.

On the other hand, $\dot{c}(0)<1$ by (11); a contradiction.
The following lemma gives the connection between the chordal and the radial case that we need for our purpose. The proof is given in Appendix A.

Lemma 4.5. Let $\gamma_{1}$ and $\gamma_{2}$ be the parametrizations of two disjoint slits in a circular slit disk $\Omega$ with $\gamma_{1}(0)=\gamma_{2}(0)=1$. In the following, $K_{t}$ is either defined by
(i) $K_{t}=\gamma_{1}[0, t]$ for all $t$ or
(ii) $K_{t}=\gamma_{1}[0, t] \cup \gamma_{2}[0, t]$ for all $t$.

Next, let $g_{t}$ be the normalized conformal mapping from $\Omega \backslash K_{t}$ onto a circular slit disk.

For $t$ small enough, we can map the hulls into the upper half-plane $\mathbb{H}$ by the mapping $F(z):=-i \log (z)($ with $\log (1)=0)$ and $A_{t}:=-i \log \left(K_{t}\right)$ will be a family of increasing $\mathbb{H}$-hulls. Then we have:
$t \mapsto \operatorname{lmr}\left(g_{t}\right)$ is differentiable at $t=0$ if and only if $t \mapsto \operatorname{hcap}\left(A_{t}\right)$ is differentiable at $t=0$. In this case

$$
\frac{d}{d t} \operatorname{hcap}\left(A_{t}\right)(0)=2 \frac{d}{d t} \operatorname{lmr}\left(g_{t}\right)(0)
$$

Now we have all means to prove Theorems 1.3 and 1.5.
Proof of Theorem 1.3. In order to get the desired example in the radial case, we take the two slits from Theorem 4.4 and map them, at least locally around 0 , into the unit disk by the mapping $z \mapsto e^{i z}$. This gives us two slits $\Gamma_{1}, \Gamma_{2}$ in the unit disk with parametrizations $\gamma_{1}, \gamma_{2}$. According to Lemma 4.5, case (i), $\gamma_{1}(t)$ and $\gamma_{2}(t)$ are Loewner parametrizations at $t=0$.

However, the mapping $t \mapsto g_{t}$ is not differentiable at $t=0$ because of Lemma 4.5, case (ii), and Theorem 1.7.

Proof of Theorem 1.5. Theorem 1.5 follows immediately from Theorem 4.3, Lemma 4.5 and Theorem 1.7.

Acknowledgement. We would like to thank the referee for the time and effort taken to review our manuscript and for the many helpful and constructive comments.

## Appendix A

Proof of Lemma 4.5. First of all we set $\Omega_{t}:=\Omega \backslash K_{t}$ and $H_{t}:=\mathbb{H} \backslash A_{t}$ Then we denote by $h_{t}: H_{t} \rightarrow \mathbb{H}$ the unique Riemann mapping with hydrodynamic normalization. Moreover we set $s_{t}:=g_{t}\left(\partial K_{t} \cap \partial \Omega_{t}\right) \subset \partial \mathbb{D}$ and $\tilde{s}_{t}:=h_{t}\left(\partial A_{t} \cap \partial H_{t}\right) \subset \partial \mathbb{H}$. Note that $g_{t}^{-1}$ and $h_{t}^{-1}$ can be extended continuously to $\partial \mathbb{D}$ and $\partial \mathbb{H}$ by Theorem 2.1 from [11], so we find

$$
\operatorname{lmr}\left(g_{t}\right)=-\frac{1}{2 \pi} \int_{s_{t}} \log \left|g_{t}^{-1}(\zeta)\right||d \zeta|
$$

$$
\operatorname{hcap}\left(A_{t}\right)=\frac{1}{\pi} \int_{\tilde{s}_{t}} \operatorname{Im}\left(h_{t}^{-1}(w)\right)|d w| .
$$

A rigorous proof of the first equation can be found in [2], equation ( $\star$ ), p. 12. The second formula can be found, e.g., in [8], equation (2.5).

If $t$ is small enough, $K_{t}$ will be close to 1 , i.e for each $\varepsilon>0$ we find a $t_{0}>0$ so that $K_{t} \subset B_{\varepsilon}(1)$ for all $t \in\left[0, t_{0}\right]$. By Schwarz reflection we see that the function

$$
T_{t}(\zeta):=g_{t}\left(\exp \left(i \cdot h_{t}^{-1}(\zeta)\right)\right)
$$

can be extended to a conformal mapping in a small neighborhood around $\tilde{s}_{k}$ for all $t \in\left[0, t_{0}\right]$. Next we get with $h_{t}^{-1}(\zeta)=-i \log \left(g_{t}^{-1}\left(T_{t}(\zeta)\right)\right)$ and by usage of the Mean-value Theorem

$$
\begin{aligned}
\operatorname{hcap}\left(A_{t}\right) & =\frac{1}{\pi} \int_{\tilde{s}_{t}} \operatorname{Im}\left(-i \log \left(g_{t}^{-1}\left(T_{t}(w)\right)\right)\right)|d w|=-\frac{1}{\pi} \int_{\tilde{s}_{t}} \log \left|g_{t}\left(T_{t}(w)\right)\right||d w| \\
& =-\frac{1}{\pi} \int_{s_{t}} \log \left|g_{t}(\zeta)\right| \frac{1}{\left|T_{t}^{\prime}\left(T_{t}^{-1}(\zeta)\right)\right|}|d \zeta|=2 \frac{1}{\left|T_{t}^{\prime}\left(\zeta_{t}\right)\right|} \operatorname{lmr}\left(K_{t}\right),
\end{aligned}
$$

where $\zeta_{t} \in \tilde{s}_{t}$. Using a normality argument analogous to the proof of Lemma 3.5, $\left|T_{t}^{\prime}(\zeta)\right|$ tends uniformly to 1 on a small neighborhood around 0 as $t \rightarrow 0$. Thus $\left|T_{t}^{\prime}\left(\zeta_{t}\right)\right| \rightarrow 1$ as $t$ tends to zero.

Proof of Theorem 1.7 (branch point case).
(a) Let $s_{t}:=g_{t}\left(\gamma_{1}[0, t] \cup \gamma_{2}[0, t]\right)$ and $F_{t}:=h_{t} \circ g_{t}^{-1}$. Then equation ( $\star$ ) on p. 12 from [2] gives us

$$
\operatorname{lmr}\left(g_{t}\right)=-\frac{1}{2 \pi} \int_{s_{t}} \log \left|g_{t}^{-1}(\zeta)\right||d \zeta|=-\frac{1}{2 \pi} \int_{s_{t}} \log \left|h_{t}^{-1}\left(F_{t}(\zeta)\right)\right||d \zeta|
$$

Next we write $\tilde{s}_{t}:=h_{t}\left(\gamma_{1}[0, t] \cup \gamma_{2}[0, t]\right)$. Each $F_{t}$ can be extended analytically to $s_{t}$, so an easy substitution combined with the Mean-value Theorem shows that

$$
\operatorname{lmr}\left(g_{t}\right)=-\frac{1}{2 \pi} \int_{\tilde{s}_{t}} \log \left|h_{t}^{-1}(w)\right| \frac{1}{\left|F_{t}^{\prime}\left(F_{t}^{-1}(w)\right)\right|}|d w|=\frac{1}{\left|F_{t}^{\prime}\left(\zeta_{t}\right)\right|} \operatorname{lmr}\left(h_{t}\right)
$$

Herein $\zeta_{t} \in s_{t}$. Finally $s_{t}$ tends to $\gamma_{1}(0)$ and $F_{t}$ can be extended to an analytic function on $B_{\varepsilon}\left(\gamma_{1}(0)\right)$ for all $t$ small enough and a small $\varepsilon>0$. Consequently $F_{t}^{\prime}\left(\zeta_{t}\right) \rightarrow 1$ as $F_{t}$ tends uniformly to the identical mapping on $B_{\varepsilon}\left(\zeta_{0}\right)$.
(b) By using the same methods as in Lemma 10 from [2] we get

$$
\log \frac{g_{t}^{-1}(z)}{z}=\frac{1}{2 \pi} \int_{s_{t}} \log \left|g_{t}^{-1}(\zeta)\right| \Phi\left(\zeta, z ; D_{t}\right)|d \zeta|
$$

Substituting $z=g_{t}(w)$ in the above equality and using the Mean-value Theorem, we get

$$
\log \frac{g_{0}(w)}{g_{t}(w)}=\frac{1}{2 \pi} \Phi\left(\zeta_{t}, g_{t}(w), D_{t}\right) \int_{s_{t}} \log \left|g_{t}^{-1}(\zeta)\right||d \zeta|=-\Phi\left(\zeta_{t}, g_{t}(w), D_{t}\right) \operatorname{lmr}\left(g_{t}\right)
$$

with $\zeta_{t} \in s_{t}$. Hereby, the continuity of $\Phi$ follows from Lemma 19 from [2]. Moreover this lemma gives $\Phi\left(\zeta_{t}, g_{t}(w), D_{t}\right) \rightarrow \Phi\left(\gamma_{1}(0), w, D_{0}\right)$ as $t$ tends to 0 , so the family $t \mapsto g_{t}$ is differentiable at 0 iff $t \mapsto \operatorname{lmr}\left(g_{t}\right)$ is differentiable.

Summarized part (a) proves (3.) $\Leftrightarrow$ (4.), part (b) proves (1.) $\Leftrightarrow$ (4.) and part (b) applied to $\Omega=\mathbb{D}$ proves $(2.) \Leftrightarrow(3$.).

[^0]:    $\left.{ }^{1}\right)$ Sometimes (e.g. in [7], p. 93), a parametrization $\gamma$ is called half-plane parametrization if $\operatorname{hcap}(\gamma(0, t])=2 t$ for all $t \in[0, T]$. The reason is explained in [7], p. 99.

[^1]:    $\left.{ }^{( }{ }^{3}\right)$ Here, $\infty$ is a boundary point of $\mathbb{H}$ on the Riemann sphere. However, in our case, kernel convergence in $\mathbb{H}$ w.r.t. $\infty$ can be defined by extending the conformal mapping $g_{A}$ analytically to $\mathbb{C} \backslash \overline{A \cup A^{*}}$, where $A^{*}$ stands for the reflection of $A$ w.r.t. the real axis.
