

## ASYMPTOTIC NORMALITY OF THE $L_1$ ERROR OF THE GRENANDER ESTIMATOR

BY PIET GROENEBOOM, GERARD HOOGHIEMSTRA AND  
HENDRIK P. LOPUHAÄ

*Delft University of Technology*

Groeneboom introduced a jump process that can be used (among other things) to study the asymptotic properties of the Grenander estimator of a monotone density. In this paper we derive the asymptotic normality of a suitably rescaled version of the  $L_1$  error of the Grenander estimator, using properties of this jump process.

**1. Introduction.** Let  $f$  be a decreasing density with support  $[0, 1]$ . Denote by  $F_n$  the empirical distribution function of a sample  $X_1, \dots, X_n$  from  $f$ . Let  $\hat{F}_n$  be the *concave majorant* of  $F_n$  on  $[0, 1]$ , by which we mean the smallest concave function such that

$$\hat{F}_n(t) \geq F_n(t), \quad t \in [0, 1] \quad \text{and} \quad \hat{F}_n(0) = 0, \quad \hat{F}_n(1) = 1.$$

The Grenander estimator  $\hat{f}_n$  is defined as the left derivative of  $\hat{F}_n$ .

In Groeneboom (1985) the asymptotic behavior of  $\hat{f}_n$  was investigated. Instead of studying the process  $\{\hat{f}_n(t), t \in (0, 1)\}$  itself, the more tractable (*inverse*) process  $\{U_n(a): a \in [f(1), f(0)]\}$  was studied, where  $U_n(a)$  is defined as the last time that the process  $F_n(t) - at$  attains its maximum,

$$(1.1) \quad U_n(a) = \sup\{t \in [0, 1]: F_n(t) - at \text{ is maximal}\}.$$

A new proof, based on the inverse process  $U_n$ , was given of a result in Prakasa Rao (1969) on pointwise weak convergence of  $\hat{f}_n$ . In Groeneboom (1985) also analytical properties of the weak limit of the locally rescaled process  $U_n(a)$  were discussed and it was indicated how the *process*  $U_n$  together with a Hungarian embedding technique could be used to prove asymptotic normality of the  $L_1$  error

$$(1.2) \quad \|\hat{f}_n - f\|_1 = \int_0^1 |\hat{f}_n(t) - f(t)| dt.$$

The analytical properties of the limit process  $a \mapsto V(a)$  were made rigorous in Groeneboom (1989) and at the same time it was mentioned that a rigorous treatment of the asymptotic normality of the  $L_1$  error would appear elsewhere. This paper fulfills that promise.

---

Received March 1998; revised June 1999.

AMS 1991 *subject classifications*. Primary 62E20, 62G05; secondary 60J65, 60J75.

*Key words and phrases*. Brownian motion with quadratic drift, central limit theorem, concave majorant, isotonic estimation, jump process,  $L_1$ -norm, monotone density.

We feel that this result is important, since the problem of estimating a monotone density is closely related to several other (inverse) problems, for example, estimation of the distribution function of interval censored data [see, e.g., Groeneboom and Wellner (1992)] and estimation of a monotone hazard function, and since the result was referred to by several authors; see, for instance, Devroye and Györfi [(1985), pages 213 and 214], Devroye [(1987), page 145], Csörgő and Horváth (1988), Birgé (1989) and Wang (1992). Recently, the result has been taken up again in the context of nonparametric regression; see Durot (1996). In fact, the methods used by Durot (1996), whose work was done independently, are closer in spirit to the methods suggested in Groeneboom (1985) than our present paper, which relies on ideas developed in Groeneboom (1989). In both settings, the proof relies heavily on the fact that Brownian motion has independent increments. One of the main differences between the model considered in Durot (1996), and the present paper is that in the regression setting one can make a direct embedding into Brownian motion, whereas in our case we can only make such an embedding into the Brownian bridge, and we need rather delicate arguments to make the transition to Brownian motion (Corollary 3.3 in the present paper).

The main result can be stated as follows. Define

$$(1.3) \quad V(c) = \sup\{t: W(t) - (t - c)^2 \text{ is maximal}\},$$

where  $\{W(t): -\infty < t < \infty\}$  denotes standard two-sided Brownian motion on  $\mathbb{R}$  originating from zero [i.e.,  $W(0) = 0$ ].

**THEOREM 1.1 (Main theorem).** *Let  $f$  be a twice differentiable decreasing density on  $[0, 1]$ , satisfying:*

- (A1)  $0 < f(1) \leq f(t) \leq f(s) \leq f(0) < \infty$ , for  $0 \leq s \leq t \leq 1$ ;
- (A2)  $0 < \inf_{t \in (0, 1)} |f'(t)| \leq \sup_{t \in (0, 1)} |f'(t)| < \infty$ ;
- (A3)  $\sup_{t \in (0, 1)} |f''(t)| < \infty$ .

Then with  $\mu = 2E|V(0)| \int_0^1 \frac{1}{2} |f'(t)f(t)|^{1/3} dt$ ,

$$n^{1/6} \left\{ n^{1/3} \int_0^1 |\hat{f}_n(t) - f(t)| dt - \mu \right\}$$

converges in distribution to a normal random variable with mean zero and variance  $\sigma^2 = 8 \int_0^\infty \text{cov}(|V(0)|, |V(c) - c|) dc$ .

Actually, this is precisely the theorem, as stated in Groeneboom (1985) (with the same conditions). In that paper, however, a sketch of proof of two pages was given, whereas, unfortunately, we need a lot more pages to write down all the details (an experience shared with Cécile Durot in her work on the regression problem.) The difficulty in proving a result of this type stems from the fact that the Grenander estimator is a nonlinear functional of the empirical distribution function. For this reason methods of proof are needed

that are very different from those used in, for example, Csörgő and Horváth (1988), where the linearity of the kernel estimators is used in an essential way.

In Section 2 we show

$$(1.4) \quad \|\hat{f}_n - f\|_1 = \int_{f(1)}^{f(0)} |U_n(a) - g(a)| da + o_p(n^{-1/2}),$$

where  $g$  denotes the inverse of  $f$  (see Corollary 2.1). In this section we also obtain an exponential upper bound for the tail probabilities of  $V_n^E(a) = n^{1/3}(U_n(a) - g(a))$ .

In Section 3 the process  $a \mapsto V_n^E(a)$  is approximated (using Hungarian embedding) by a process  $a \mapsto V_n^B(a)$ , defined for the Brownian bridge. The process  $V_n^B$  is in turn approximated by a similar process  $a \mapsto V_n^W(a)$ , defined for Brownian motion. A key tool for the results in this section is Lemma 3.4, showing that the probability of a jump of  $V_n^B$  and  $V_n^W$  in an interval of length  $hn^{-1/3}$  is of order  $h$ , if  $h$  is not too small. We suspect that the restriction “not too small” is actually not needed, but this restriction arises naturally in the present approach. The methods in this section are motivated by results that hold in the “canonical setting” of the process  $V$ , studied in Groeneboom (1989).

Another key observation that makes things work in Section 3 is that, although we cannot construct a Brownian motion and a Brownian bridge which are close in the supremum distance on  $[0, 1]$ , we have that, if

$$W(F(t)) = B(F(t)) + \xi F(t),$$

where  $B$  is the Brownian bridge on  $[0, 1]$ , and  $\xi$  is a standard normal random variable, independent of  $B$ , the associated processes of locations of maxima  $V_n^B$  and  $V_n^W$ , defined for  $B \circ F$  and  $W \circ F$ , respectively, are very close indeed.

The results in Section 3 imply that it is sufficient to prove that

$$n^{1/6} \int_{f(1)}^{f(0)} (|V_n^W(a)| - E|V_n^W(a)|) da$$

tends in distribution to a normal distribution with expectation 0 and variance  $\sigma^2$ , where  $\sigma^2$  is given in Theorem 1.1. In Section 3 the process  $V_n^W$  is also shown to be strongly mixing. This leads to a central limit theorem which is proved in Section 4 by using Bernstein’s method of big blocks and small blocks. Throughout, it will be assumed that conditions (A1) to (A3) hold.

**2. Localization.** In this section we show that the distributions of the random variables

$$(2.1) \quad V_n^E(a) = n^{1/3}(U_n(a) - g(a))$$

have exponentially fast decreasing tails. This will enable us to compare the process  $U_n$  locally with a similar process, defined for the Brownian bridge.

For  $s \leq t$ , we use the following abbreviations:

$$\begin{aligned} F_n(s, t) &= F_n(t) - F_n(s), \\ F(s, t) &= F(t) - F(s). \end{aligned}$$

LEMMA 2.1. *Let  $a \in [f(1), f(0)]$  and let  $t_0 = g(a)$ . Then*

$$P\{V_n^E(a) > x\} \leq P\left\{ \sup_{t \in [t_0 + xn^{-1/3}, 1]} \frac{F_n(t_0, t)}{F(t_0, t)} \geq \frac{f(t_0)xn^{-1/3}}{F(t_0, t_0 + xn^{-1/3})} \right\},$$

for each  $x$  such that  $t_0 < t_0 + xn^{-1/3} \leq 1$ , and

$$P\{V_n^E(a) < -x\} \leq P\left\{ \inf_{t \in [0, t_0 - xn^{-1/3}]} \frac{F_n(t, t_0)}{F(t, t_0)} \leq \frac{f(t_0)xn^{-1/3}}{F(t_0 - xn^{-1/3}, t_0)} \right\},$$

for each  $x$  such that  $0 \leq t_0 - xn^{-1/3} < t_0$ .

PROOF. For each  $x$ , such that  $t_0 < t_0 + xn^{-1/3} \leq 1$ , we have

$$(2.2) \quad P\{V_n^E(a) > x\} \leq P\{F_n(t_0, t) - a(t - t_0) \geq 0, \text{ for some } t \in (t_0 + xn^{-1/3}, 1]\},$$

and for each  $x$  such that  $0 \leq t_0 - xn^{-1/3} < t_0$ ,

$$(2.3) \quad P\{V_n^E(a) < -x\} \leq P\{F_n(t, t_0) - a(t_0 - t) \leq 0, \text{ for some } t \in [0, t_0 - xn^{-1/3}]\}.$$

The probability on the right-hand side of (2.2) can be written as

$$(2.4) \quad P\left\{ \frac{F_n(t_0, t)}{F(t_0, t)} \geq \frac{f(t_0)(t - t_0)}{F(t_0, t)}, \text{ for some } t \in (t_0 + xn^{-1/3}, 1] \right\}.$$

Since the function

$$\gamma(t) = \frac{f(t_0)(t - t_0)}{F(t_0, t)}$$

is increasing for  $t \in (t_0, 1)$  (using the monotonicity of  $f$ ), it follows that (2.4) is bounded above by

$$P\left\{ \sup_{t \in (t_0 + xn^{-1/3}, 1]} \frac{F_n(t_0, t)}{F(t_0, t)} \geq \frac{f(t_0)xn^{-1/3}}{F(t_0, t_0 + xn^{-1/3})} \right\}.$$

Similarly, the probability on the right-hand side of (2.3) can be bounded from above by

$$P\left\{ \inf_{t \in [0, t_0 - xn^{-1/3}]} \frac{F_n(t, t_0)}{F(t, t_0)} \leq \frac{f(t_0)xn^{-1/3}}{F(t_0 - xn^{-1/3}, t_0)} \right\}. \quad \square$$

To bound the probabilities given in Lemma 2.1, we will apply Doob's inequality to suitably chosen martingales. These martingales are given in the next lemma.

LEMMA 2.2. *Let  $0 \leq t_0 \leq 1$ . Consider, for  $n$  fixed, the processes*

$$t \mapsto M_{1n}(t) = \frac{F_n(t_0, t)}{F(t_0, t)}, \quad t \in (t_0, 1]$$

and

$$t \mapsto M_{2n}(t) = \frac{F_n(t, t_0)}{F(t, t_0)}, \quad t \in [0, t_0).$$

Let  $\mathcal{F}_s = \sigma\{F_n(t): t \in [s, 1]\}$  and  $\mathcal{G}_s = \sigma\{F_n(t): t \in [0, s]\}$ . Then, conditionally on  $F_n(t_0)$ , the process  $M_{1n}$  is a reverse time martingale with respect to the filtration  $\{\mathcal{F}_s: s \in (t_0, 1]\}$  and  $M_{2n}$  is a forward time martingale with respect to the filtration  $\{\mathcal{G}_s: s \in [0, t_0)\}$ .

PROOF. Note that conditionally on  $F_n(t_0)$  and  $F_n(t_0, s)$ , for  $t_0 < t < s < 1$ , the random variable  $nF_n(t_0, t)$  has a binomial distribution with parameter  $nF_n(t_0, s)$  and probability of success  $p = F(t_0, t)/F(t_0, s)$ . This shows that for  $t < s$ ,

$$E_0[F_n(t_0, t) | \mathcal{F}_s] = F_n(t_0, s) \frac{F(t_0, t)}{F(t_0, s)},$$

where  $E_0(\cdot) = E[\cdot | F_n(t_0)]$ . This implies that for  $t_0 < t < s < 1$ , we have that

$$E_0[M_{1n}(t) | \mathcal{F}_s] = M_{1n}(s).$$

Similarly, conditionally on  $F_n(t_0)$  and  $F_n(s, t_0)$ , for  $0 < s < t < t_0$ , the random variable  $nF_n(t, t_0)$  has a binomial distribution with parameters  $nF_n(s, t_0)$  and  $p = F(t, t_0)/F(s, t_0)$ . This leads to

$$E_0[M_{2n}(t) | \mathcal{G}_s] = M_{2n}(s). \quad \square$$

We have the following bounds for the martingales in Lemma 2.2.

LEMMA 2.3. *Let  $h(y) = 1 - y + y \log y$ ,  $y > 0$ . Then, for  $t_0 \in [0, 1)$ ,  $y \geq 1$  and  $\delta > 0$  such that  $t_0 + \delta < 1$ ,*

$$P\left\{ \sup_{t \in [t_0 + \delta, 1]} M_{1n}(t) \geq y \right\} \leq \exp\{-nF(t_0, t_0 + \delta)h(y)\}$$

and for  $t_0 \in (0, 1]$ ,  $0 < y \leq 1$  and  $\delta > 0$  such that  $t_0 - \delta > 0$ ,

$$P\left\{ \inf_{t \in [0, t_0 - \delta]} M_{2n}(t) \leq y \right\} \leq \exp\{-nF(t_0 - \delta, t_0)h(y)\}.$$

PROOF. We start with the proof of the first inequality. According to Lemma 2.2 we have that for each  $r > 0$ , conditionally on  $F_n(t_0)$ , the process

$\exp\{rM_{1n}(t)\}$  is a reverse time submartingale. Hence, by Doob's inequality,

$$\begin{aligned} P\left\{\sup_{t \in [t_0 + \delta, 1]} M_{1n}(t) \geq y\right\} &= E\left[P\left\{\sup_{t \in [t_0 + \delta, 1]} M_{1n}(t) \geq y \mid F_n(t_0)\right\}\right] \\ &= E\left[P\left\{\sup_{t \in [t_0 + \delta, 1]} \exp(rM_{1n}(t)) \geq e^{ry} \mid F_n(t_0)\right\}\right] \\ &\leq E\left[e^{-ry} E(\exp(rM_{1n}(t_0 + \delta)) \mid F_n(t_0))\right] \\ &= e^{-ry} E \exp(rM_{1n}(t_0 + \delta)). \end{aligned}$$

Using the fact that  $nF_n(t_0, t_0 + \delta)$  has a binomial distribution with parameters  $n$  and  $p = F(t_0, t_0 + \delta)$ , we see that the last expression is equal to

$$e^{-ry} (1 + p(e^{r/np} - 1))^n \leq e^{-ry} \exp(np(e^{r/np} - 1)) = e^{-nph(y)},$$

by putting  $r = np \log y$  in the last equality. This proves the first exponential bound.

For the proof of the second inequality we note that, for  $y \in (0, 1]$ ,

$$\begin{aligned} P\left\{\inf_{t \in [0, t_0 - \delta]} M_{2n}(t) \leq y\right\} &= E\left[P\left\{\sup_{t \in [0, t_0 - \delta]} -M_{2n}(t) \geq -y \mid F_n(t_0)\right\}\right] \\ &\leq E\left[e^{ry} E(\exp(-rM_{2n}(t_0 - \delta)) \mid F_n(t_0))\right] \\ &= e^{ry} E \exp(-rM_{2n}(t_0 - \delta)), \end{aligned}$$

where again Doob's inequality is used. Taking  $p = F(t_0 - \delta, t_0)$  and  $r = -np \log y$ , we get

$$e^{ry} E \exp(-rM_{2n}(t_0 - \delta)) \leq \exp(-nph(y)). \quad \square$$

REMARK. The function  $y \mapsto h(y)$ , used in Lemma 2.3, but also in the sequel, is a well-known function in large deviation theory. It is nonnegative and convex on  $(0, \infty)$ . Its minimum 0 is attained at  $y = 1$ . Actually  $h(y) = \int_1^y \log u \, du$ ,  $y > 0$ .

We are now ready to prove the following theorem.

THEOREM 2.1. *Let  $V_n^E(a)$  be defined by (2.1). Then there exists a constant  $C > 0$ , only depending on  $f$ , such that for all  $n \geq 1$ ,  $a \in [f(1), f(0)]$  and  $x > 0$ ,*

$$P\{|V_n^E(a)| > x\} \leq 2e^{-Cx^3}.$$

PROOF. We will write  $\delta_n = xn^{-1/3}$ . First consider the probability

$$(2.5) \quad P\{V_n^E(a) > x\}.$$

If  $g(a) + \delta_n \geq 1$ , this probability is zero, in which case there is nothing to prove, so we can restrict ourselves to values of  $x > 0$ , such that  $g(a) + \delta_n < 1$ .

Let

$$y_n = \frac{f(t_0)\delta_n}{F(t_0, t_0 + \delta_n)},$$

where  $t_0 = g(a)$ . Note that  $y_n > 1$ , since  $f$  is strictly decreasing. We also have, using assumption (A1),

$$y_n = \frac{f(t_0)\delta_n}{F(t_0, t_0 + \delta_n)} \leq \frac{f(t_0)}{f(t_0 + \delta_n)} \leq \frac{f(0)}{f(1)} < \infty.$$

Hence  $1 < y_n < c_1$ , for a constant  $c_1 > 0$ , independent of  $x$  such that  $t_0 + \delta_n < 1$ . By Lemma 2.1, the probability in (2.5) is bounded above by

$$P\left\{ \sup_{t \in [t_0 + \delta_n, 1]} M_{1n}(t) \geq y_n \right\}.$$

According to Lemma 2.3 this probability is bounded by

$$(2.6) \quad \exp\{-nF(t_0, t_0 + \delta_n)h(y_n)\}.$$

Using a Taylor expansion with a Lagrangian remainder term of the convex function  $u \mapsto h(u)$  at  $u = 1$ , we get

$$(2.7) \quad h(y_n) = \frac{1}{2}h''(\xi_n)(y_n - 1)^2 \geq \frac{1}{2}c_1^{-1}(y_n - 1)^2,$$

where  $1 \leq \xi_n \leq c_1$ . However,

$$|y_n - 1| \geq \frac{\delta_n \inf_{u \in (0,1)} |f'(u)|}{2f(0)},$$

and hence, by (2.7),

$$h(y_n) \geq c_2 \delta_n^2,$$

for a constant  $c_2 > 0$ , independent of  $x$  such that  $t_0 + \delta_n < 1$ . Since  $F(t_0, t_0 + \delta_n) \geq f(1)\delta_n$ , it now follows that (2.6) is bounded above by  $\exp(-Cx^3)$ .

Now consider the probability

$$(2.8) \quad P\{V_n^E(a) < -x\}.$$

If  $g(a) - xn^{-1/3} \leq 0$ , this probability is zero, so we can restrict ourselves to consider an  $x > 0$  such that  $g(a) - xn^{-1/3} > 0$ . Define

$$y_n = \frac{f(t_0)\delta_n}{F(t_0 - \delta_n, t_0)}.$$

The fact that  $f$  is strictly decreasing, this time implies that  $y_n < 1$ . Using Lemma 2.1, it is seen that (2.8) is bounded above by

$$P\left\{ \inf_{t \in [0, t_0 - \delta_n]} M_{2n}(t) \leq y_n \right\},$$

which, by Lemma 2.3, leads to the upper bound

$$\exp\{-nf(1)\delta_n h(y_n)\}.$$

We have, using  $h''(x) \geq 1, x \in (0, 1]$ ,

$$h(y_n) = \frac{1}{2}h''(\xi_n)(y_n - 1)^2 \geq \frac{1}{2}(y_n - 1)^2,$$

where in this case  $0 < \xi_n \leq 1$ . Following the same line of argument as above, we get the upper bound  $\exp\{-Cx^3\}$ .  $\square$

Lemma 2.3 also enables us to show that the difference between the  $L_1$  risk in (1.2) and the integral

$$\int_{f(1)}^{f(0)} |U_n(a) - g(a)| da,$$

defined in terms of the inverse process, is  $o_p(n^{-1/2})$ .

**COROLLARY 2.1.** *Let  $\hat{f}_n$  be the Grenander estimator and let  $U_n$  be defined in (1.1). Then*

$$(2.9) \quad \int_0^1 |\hat{f}_n(t) - f(t)| dt - \int_{f(1)}^{f(0)} |U_n(a) - g(a)| da = O_p(n^{-2/3}).$$

**PROOF.** The difference on the left-hand side of (2.9) can be written as

$$\int_0^1 [\hat{f}_n(t) - f(0)]^+ dt + \int_0^1 [f(1) - \hat{f}_n(t)]^+ dt,$$

where  $x^+ = \max(0, x), x \in \mathbb{R}$ . We will show that the first term is  $O_p(n^{-2/3})$ . The second term can be treated similarly.

We have that

$$\begin{aligned} & \int_0^1 [\hat{f}_n(t) - f(0)]^+ dt \\ &= \int_0^{U_n(f(0))} (\hat{f}_n(t) - f(0)) dt = F_n(U_n(f(0))) - f(0)U_n(f(0)) \\ &= F_n(U_n(f(0))) - F(U_n(f(0))) + F(U_n(f(0))) - f(0)U_n(f(0)). \end{aligned}$$

According to Theorem 2.1, for the second difference on the right-hand side we have

$$(2.10) \quad |F(U_n(f(0))) - f(0)U_n(f(0))| \leq \frac{1}{2} \sup |f'| U_n(f(0))^2 = O_p(n^{-2/3}).$$

Let  $Z_n = F_n(U_n(f(0))) - F(U_n(f(0)))$  and  $\delta_n = n^{-1/3} \log n$ . Then write

$$Z_n = Z_n \mathbf{1}_{\{U_n(f(0)) > \delta_n\}} + Z_n \mathbf{1}_{\{U_n(f(0)) \leq \delta_n\}}.$$

Then, according to Theorem 2.1,

$$E|Z_n| \mathbf{1}_{\{U_n(f(0)) > \delta_n\}} \leq 2P\{U_n(f(0)) > \delta_n\} \leq 4 \exp(-C(\log n)^3).$$

Hence by the Markov inequality we can conclude that

$$(2.11) \quad Z_n \mathbf{1}_{\{U_n(f(0)) > \delta_n\}} = o_p(n^{-2/3}).$$

Let  $(B_n)$  be a sequence of Brownian bridges given by the Hungarian embedding approximating  $n^{1/2}(F_n - F)$  [cf. Kósmos, Major and Tusnády (1975)]. Then

$$|Z_n \mathbf{1}_{\{U_n(f(0)) \leq \delta_n\}} \leq n^{-1/2} \sup_{t \in [0, F(\delta_n)]} |B_n(t)| + O_p(n^{-1} \log n).$$

Since  $B_n(t) \stackrel{d}{=} W(t) + tW(1)$ , where  $W$  denotes Brownian motion, the right-hand side can be bounded by a random variable that has the same distribution as

$$n^{-1/2} \sup_{t \in [0, F(\delta_n)]} |W(t)| + n^{-1/2} F(\delta_n) |W(1)| + O_p(n^{-1} \log n).$$

Note that  $F(\delta_n) |W(1)| = O_p(\delta_n)$ . Furthermore, since for any  $\varepsilon > 0$ ,

$$P \left\{ \sup_{t \in [0, F(\delta_n)]} |W(t)| > \varepsilon \right\} \leq 4P \left\{ W(1) \geq \frac{\varepsilon}{F(\delta_n)^{1/2}} \right\},$$

we have that

$$n^{-1/2} \sup_{t \in [0, F(\delta_n)]} |W(t)| = o_p(n^{-2/3}),$$

which implies that  $Z_n \mathbf{1}_{\{U_n(f(0)) \leq \delta_n\}} = o_p(n^{-2/3})$ . Together with (2.10) and (2.11) this proves that

$$\int_0^1 [\hat{f}_n(t) - f(0)]^+ dt = O_p(n^{-2/3}). \quad \square$$

**3. Brownian motion approximation.** In this section we show that it is sufficient to prove Theorem 1.1 for a similar process, with Brownian motion replacing the empirical process. Let  $E_n$  denote the empirical process  $\sqrt{n}(F_n - F)$  and let  $V_n^E(a)$  be defined as in (2.1). Then we have, for fixed  $a \in (f(1), f(0))$ ,

$$(3.1) \quad V_n^E(a) = \operatorname{argmax}_t \{D_n^E(a, t) - n^{1/3}at\},$$

where  $t \mapsto D_n^E(a, t)$  is the drifting empirical process

$$D_n^E(a, t) = n^{1/6} \{E_n(g(a) + n^{-1/3}t) - E_n(g(a))\} + n^{2/3} \{F(g(a) + n^{-1/3}t) - F(g(a))\},$$

and where the  $\operatorname{argmax}$  is taken over all values of  $t$  such that

$$g(a) + n^{-1/3}t \in [0, 1].$$

Here the  $\operatorname{argmax}$  function is the supremum of the times at which the maximum is attained (in order to have a well-defined functional also on sets of probability zero).

Let Brownian bridge  $B_n$  and the uniform empirical process  $E_n \circ F^{-1}$  be constructed on the same probability space via the Hungarian embedding of K6mlos, Major and Tusn6dy (1975). Let

$$(3.2) \quad V_n^B(a) = \operatorname{argmax}_t \{D_n^B(a, t) - n^{1/3}at\},$$

where

$$(3.3) \quad \begin{aligned} D_n^B(a, t) = n^{1/6} \{ & B_n(F(g(a) + n^{-1/3}t)) - B_n(F(g(a))) \} \\ & + n^{2/3} \{ F(g(a) + n^{-1/3}t) - F(g(a)) \}. \end{aligned}$$

Then (3.1) suggests that  $V_n^E(a)$  is close to  $V_n^B(a)$ . We will show that this is indeed the case. We define versions  $W_n$  of Brownian motion by

$$(3.4) \quad W_n(t) = B_n(t) + \xi_n t, \quad t \in [0, 1],$$

where  $\xi_n$  is a standard normal random variable, independent of  $B_n$ . Moreover, let

$$(3.5) \quad V_n^W(a) = \operatorname{argmax}_t \{D_n^W(a, t) - n^{1/3}at\},$$

where

$$(3.6) \quad \begin{aligned} D_n^W(a, t) = n^{1/6} \{ & W_n(F(g(a) + n^{-1/3}t)) - W_n(F(g(a))) \} \\ & + n^{2/3} \{ F(g(a) + n^{-1/3}t) - F(g(a)) \}. \end{aligned}$$

Note that  $V_n^B(a)$  and  $V_n^W(a)$  are defined in the same way as  $V_n^E(a)$ , but with  $E_n$  replaced by  $B_n \circ F$  and  $W_n \circ F$ , respectively. For  $J = E, B, W$ , the  $\operatorname{argmax} V_n^J(a)$  can be seen as the  $t$ -coordinate of the point that is touched first when dropping a line with slope  $n^{1/3}a$  on the process  $t \mapsto D_n^J(a, t)$ . Furthermore, note that for every fixed  $a, b \in (f(1), f(0))$ , we have the following property:

$$(3.7) \quad V_n^J(b) + n^{1/3}(g(b) - g(a)) = \operatorname{argmax}_t \{D_n^J(a, t) - n^{1/3}bt\},$$

where as before the  $\operatorname{argmax}$  is taken over values of  $t$  such that

$$g(a) + n^{-1/3}t \in [0, 1].$$

Hence (3.7) is the  $t$ -coordinate of the point that is touched first when dropping a line with slope  $n^{1/3}b$  on the process  $t \mapsto D_n^J(a, t)$ . Moreover, note that

$$(3.8) \quad \begin{aligned} c \mapsto V_n^J(c) + n^{1/3}(g(c) - g(a)) \text{ jumps at } b \\ \text{if and only if } c \mapsto V_n^J(c) \text{ jumps at } b. \end{aligned}$$

We have the following results for  $V_n^B(a)$  and  $V_n^W(a)$ , analogous to Theorem 2.1.

**THEOREM 3.1.** *Let  $V_n^B(a)$  and  $V_n^W(a)$  be defined by (3.2) and (3.5), respectively. Then there exist a constant  $C > 0$ , only depending on  $f$ , such that for all  $n \geq 1$ ,  $a \in (f(1), f(0))$  and  $x > 0$ ,*

$$P\{|V_n^W(a)| > x\} \leq 2 \exp(-Cx^3) \quad \text{and} \quad P\{|V_n^B(a)| > x\} \leq 4 \exp(-Cx^3).$$

PROOF. Let  $a \in (f(1), f(0))$  and let  $t_0 = g(a)$ . We first consider

$$P\{V_n^W(a) > x\}.$$

If  $t_0 + xn^{-1/3} \geq 1$ , this probability is zero, so we may assume  $t_0 + xn^{-1/3} < 1$ . Let the process  $t \mapsto X_n^W(a, t)$  be defined by

$$(3.9) \quad X_n^W(a, t) = n^{1/6}\{W_n(F(g(a) + n^{-1/3}t)) - W_n(F(g(a)))\}, \\ t \in [0, n^{1/3}(1 - g(a))],$$

and let, for  $r \in \mathbb{R}$ , the process  $Y_n$  be defined by

$$(3.10) \quad Y_n(t) = \frac{\exp(rX_n^W(a, t))}{E \exp(rX_n^W(a, t))}, \quad t \in [0, n^{1/3}(1 - t_0)].$$

Then  $Y_n$  is a martingale with respect to the filtration induced by  $t \mapsto X_n^W(a, t)$  and

$$E \exp(rX_n^W(a, t)) = \exp\{\frac{1}{2}r^2n^{1/3}F(t_0, t_0 + n^{-1/3}t)\}.$$

We now define the stopping time  $\tau_n$  by

$$\tau_n = \inf\{t \in [x, n^{1/3}(1 - t_0)]: Z_n^W(a, t) \geq 0\},$$

where  $Z_n^W(a, t) = D_n^W(a, t) - n^{1/3}at$ , with  $D_n^W$  defined in (3.6). If  $Z_n^W(a, t) < 0$  for all  $t \in [x, n^{1/3}(1 - t_0)]$ , we define  $\tau_n = \infty$ . By the optional stopping theorem [cf. Rogers and Williams (1997), page 189] we have

$$EY_n(\tau_n \wedge n^{1/3}(1 - t_0)) = EY_n(0) = 1.$$

On the other hand,

$$EY_n(\tau_n \wedge n^{1/3}(1 - t_0)) \geq EY_n(\tau_n)\mathbf{1}_{\{\tau_n < \infty\}} \\ \geq E \exp\{-n^{2/3}rF(t_0, t_0 + n^{-1/3}\tau_n) + n^{1/3}ra\tau_n \\ - \frac{1}{2}r^2n^{1/3}F(t_0, t_0 + n^{-1/3}\tau_n)\}\mathbf{1}_{\{\tau_n < \infty\}} \\ \geq E \exp\{c_1r\tau_n^2 - c_2r^2\tau_n\}\mathbf{1}_{\{\tau_n < \infty\}},$$

where  $c_1 = \frac{1}{2}\inf_{t \in (0, 1)}|f'(t)|$  and  $c_2 = \frac{1}{2}f(0)$ . If we take  $r = c_1x/(2c_2)$  and  $C = c_1^2/(4c_2)$ , we conclude that

$$1 = EY_n(\tau_n \wedge n^{1/3}(1 - t_0)) \geq E \exp\{Cx\tau_n(2\tau_n - x)\}\mathbf{1}_{\{\tau_n < \infty\}} \\ \geq \exp\{Cx^3\}P\{\tau_n < \infty\}.$$

Hence we find

$$P\{V_n^W(a) > x\} \leq P\left\{\sup_{t \in [x, n^{1/3}(1 - t_0)]} Z_n^W(a, t) \geq 0\right\} = P\{\tau_n < \infty\} \leq \exp\{-Cx^3\}.$$

For the opposite inequality we note that

$$P\{V_n^W(a) < -x\} \leq P\left\{\sup_{t \in [x, n^{1/3}t_0]} Z_n^W(a, -t) \geq 0\right\}.$$

This can be bounded in the same way as before, by introducing the stopping time

$$\tilde{\tau}_n = \inf\{t \in [x, n^{1/3}t_0]: Z_n^W(a, -t) \geq 0\},$$

and applying the optional stopping argument to the backward time martingale

$$\tilde{Y}_n(t) = \frac{\exp(rX_n^W(a, -t))}{E \exp(rX_n^W(a, -t))}, \quad t \in [0, n^{1/3}t_0].$$

For the argmax associated with the Brownian bridge we have with (3.4),

$$V_n^B(a) = \operatorname{argmax}_t \{Z_n^W(a, t) - n^{1/6}F(t_0, t_0 + n^{-1/3}t)\xi_n\}.$$

Now choose  $\delta > 0$  in such a way that  $\delta f(0) < \frac{1}{4} \inf_{t \in (0, 1)} |f'(t)|$ , and note that for  $x < n^{1/3}$ ,

$$P\{|\xi_n| > \delta n^{1/6}x\} \leq \exp\{-\frac{1}{2}\delta^2 n^{1/3}x^2\} \leq \exp\{-\frac{1}{2}\delta^2 x^3\}.$$

Hence

$$\begin{aligned} P\{V_n^B(a) > x\} &\leq P\left\{ \sup_{t \in [x, n^{1/3}(1-t_0)]} (Z_n^W(a, t) + \delta x n^{1/3}F(t_0, t_0 + n^{-1/3}t)) \geq 0 \right\} \\ &\quad + \exp(-\frac{1}{2}\delta^2 x^3) \\ &\leq P\left\{ \sup_{t \in [x, n^{1/3}(1-t_0)]} (X_n^W(a, t) - c_1' t^2) \geq 0 \right\} + \exp(-\frac{1}{2}\delta^2 x^3), \end{aligned}$$

with  $c_1' = \frac{1}{4} \inf_{t \in (0, 1)} |f'(t)|$ . Repeating the above optional stopping argument with  $\tau_n$  replaced by the stopping time

$$(3.11) \quad \tau_n' = \inf\{t \in [x, n^{1/3}(1-t_0)]: X_n^W(a, t) - c_1' t^2 \geq 0\},$$

the first probability in the last expression is bounded from above by  $\exp(-C'x^3)$ , where  $C' = (c_1')^2/(4c_2)$ , with  $c_2$  as before. It follows that

$$P\{V_n^B(a) > x\} \leq 2e^{-Cx^3},$$

for all  $x > 0$  and some  $C > 0$ , only depending on  $f$ . Similarly,

$$P\{V_n^B(a) < -x\} \leq P\left\{ \sup_{t \in [x, n^{1/3}t_0]} (X_n^W(a, -t) - c_1' t^2) \geq 0 \right\} + \exp(-\frac{1}{2}\delta^2 x^3).$$

The bound on  $P\{V_n^B(a) < -x\}$  is obtained by using the stopping time

$$\tilde{\tau}_n' = \inf\{t \in [x, n^{1/3}t_0]: X_n^W(a, -t) - c_1' t^2 \geq 0\}$$

and applying the optimal stopping argument to the backward time martingale  $\tilde{Y}_n(t)$ .  $\square$

REMARK 3.1. Theorem 3.1 for  $V_n^W$  holds more generally. Let  $L_n(a)$  be the location of the maximum of the process  $t \mapsto X_n^W(a, t) - \Delta_n(a, t)$ , where  $X_n^W$  is defined in (3.9) and  $\Delta_n(a, t) \geq c_1 t^2$ , uniformly for  $t \in [0, n^{1/3}(t_0 \vee (1 - t_0))]$ . By the same argument as in the proof of Theorem 3.1, it follows that  $P\{|L_n(a)| > x\} \leq 2 \exp(-Cx^3)$ , where  $C$  only depends on  $c_1$ .

The following theorem shows that properly normalized versions of  $V_n^J(a)$  converge in distribution to a centered version of (1.3). For  $a \in (f(1), f(0))$ , let

$$J_n(a) = \{c: a - \phi_2(a)cn^{-1/3} \in (f(1), f(0))\},$$

and for  $J = E, B, W$  and  $c \in J_n(a)$ , we define,

$$(3.12) \quad V_{n,a}^J(c) = \phi_1(a)V_n^J(a - \phi_2(a)cn^{-1/3}),$$

where

$$\phi_1(a) = \frac{|f'(g(a))|^{2/3}}{(4a)^{1/3}} > 0,$$

$$\phi_2(a) = (4a)^{1/3}|f'(g(a))|^{1/3} > 0.$$

For  $c \in \mathbb{R}$ , let

$$(3.13) \quad \xi(c) = V(c) - c,$$

with  $V(c)$  defined in (1.3).

THEOREM 3.2. For  $J = E, B, W$ ,  $d \geq 1$ ,  $a \in (f(1), f(0))$  and  $c \in J_n(a)^d$ , we have joint distributional convergence of  $(V_{n,a}^J(c_1), \dots, V_{n,a}^J(c_d))$  to the random vector  $(\xi(c_1), \dots, \xi(c_d))$ .

PROOF. First consider  $V_{n,a}^W(c)$  in the case  $d = 1$ . Using (3.7) with  $b = a - \phi_2(a)cn^{-1/3}$ , we have that

$$\begin{aligned} \tilde{V}_{n,a}^W(c) &= \phi_1(a)V_n^W(a - \phi_2(a)cn^{-1/3}) \\ &\quad + \phi_1(a)n^{1/3}\{g(a - \phi_2(a)cn^{-1/3}) - g(a)\}, \end{aligned}$$

is the argmax of the process  $t \mapsto Z_{n,a}^W(c, t)$ , where

$$\begin{aligned} Z_{n,a}^W(c, t) &= \frac{\phi_1(a)^{1/2}}{a^{1/2}}n^{1/6}\{W_n(F(g(a) + n^{-1/3}\phi_1(a)^{-1}t)) - W_n(F(g(a)))\} \\ &\quad + \frac{\phi_1(a)^{1/2}}{a^{1/2}}n^{2/3}\{F(g(a) + n^{-1/3}\phi_1(a)^{-1}t) \\ &\quad \quad - F(g(a)) - n^{-1/3}a\phi_1(a)^{-1}t\} + 2ct. \end{aligned}$$

Note that  $\phi_1(a)n^{1/3}(g(a - \phi_2(a)cn^{-1/3}) - g(a))$  converges to  $c$ , as  $n \rightarrow \infty$ . By using Brownian scaling, a simple Taylor expansion and the uniform continuity of Brownian motion on compacta, for each  $k = 1, 2, \dots$  and each  $c \in J_n(a)$

we have

$$\sup_{|t| \leq k} |Z_{n,a}^w(c, t) - Z(c, t)| \rightarrow_P 0, \quad \text{as } n \rightarrow \infty,$$

where

$$Z(c, t) = \left( \frac{\phi_1(a)}{a} \right)^{1/2} W\left( \frac{at}{\phi_1(a)} \right) - (t^2 - 2ct) =_d W(t) - t^2 + 2ct.$$

Now let  $d \geq 1$  and note that for  $t = (t_1, \dots, t_d)$ ,

$$\begin{aligned} (\tilde{V}_{n,a}^w(c_1), \dots, \tilde{V}_{n,a}^w(c_d)) &= \operatorname{argmax}_t \sum_{i=1}^d Z_{n,a}^w(c_i, t_i), \\ (V(c_1), \dots, V(c_d)) &= \operatorname{argmax}_t \sum_{i=1}^d Z(c_i, t_i). \end{aligned}$$

Finally, because

$$\sup_{\|t\| \leq k} \left| \sum_{i=1}^d Z_{n,a}^w(c_i, t_i) - \sum_{i=1}^d Z(c_i, t_i) \right| \leq \sum_{i=1}^d \sup_{|t_i| \leq k} |Z_{n,a}^w(c_i, t_i) - Z(c_i, t_i)|,$$

we conclude that the process  $t \mapsto \sum_{i=1}^d Z_{n,a}^w(c_i, t_i)$  converges in the uniform topology on compacta to the process  $t \mapsto \sum_{i=1}^d Z(c_i, t_i)$ . The result for  $V_n^w$  follows from Theorem 2.7 in Kim and Pollard (1990).

Using (3.4) we can prove the same result for  $V_n^B$  by repeating the above steps, since  $n^{-1/6} \xi_n t \rightarrow 0$  in probability, uniformly in  $t$  on compacta of  $\mathbb{R}$ . Finally, by using  $\sup_{t \in \mathbb{R}} |D_n^E(a, t) - D_n^B(a, t)| = O_p(n^{-1/2} \log n)$ , the same result follows for  $V_n^E$ .  $\square$

We will need some independence structure for the process  $\{U_n^w(a), a \in (f(1), f(0))\}$ , where

$$U_n^w(a) = \operatorname{argmax}_{t \in [0, 1]} \{W_n(F(t)) + \sqrt{n}(F(t) - at)\}.$$

The mixing property of the process  $U_n^w$  can be argued intuitively in the following way. Observe that the event  $\{U_n^w(a) = x\}$  is equivalent to

$$\begin{aligned} W_n(F(x)) - W_n(F(t)) &\geq \sqrt{n}(F(t) - F(x)) + a\sqrt{n}(x - t), & t < x, \\ W_n(F(x)) - W_n(F(t)) &> \sqrt{n}(F(t) - F(x)) + a\sqrt{n}(x - t), & t > x. \end{aligned}$$

These are conditions on increments of  $W_n \circ F$ . Since for large  $M$ , the event  $|U_n^w(a) - g(a)| < n^{-1/3}M$  has a probability close to 1, we can restrict  $t$  and  $x$  to  $n^{-1/3}M$ -neighborhoods of  $g(a)$ . The mixing property then follows from the fact that Brownian motion has independent increments.

**THEOREM 3.3.** *The process  $\{U_n^w(a): a \in (f(1), f(0))\}$  is strong mixing with mixing function,*

$$(3.14) \quad \alpha_n(d) = 12 \exp(-C_1 nd^3),$$

where the constant  $C_1 > 0$  only depends on  $f$ . More specifically, for arbitrary  $a \in (f(1), f(0))$  and  $a + d \in (f(1), f(0))$ ,

$$\sup |P(A \cap B) - P(A)P(B)| \leq \alpha_n(d),$$

where the supremum is taken over all sets  $A \in \sigma\{U_n^W(c): f(1) < c \leq a\}$  and  $B \in \sigma\{U_n^W(c): a + d \leq c < f(0)\}$ .

PROOF. Let  $a \in (f(1), f(0))$  be arbitrary and take  $f(1) < a_1 \leq a_2 \leq \dots \leq a_k = a < a + d = c_1 \leq c_2 \leq \dots \leq c_l < f(0)$  and consider the events

$$E_1 = \{U_n^W(a_1) \in A_1, \dots, U_n^W(a_k) \in A_k\},$$

$$E_2 = \{U_n^W(c_1) \in B_1, \dots, U_n^W(c_l) \in B_l\},$$

for Borel sets  $A_1, \dots, A_k$  and  $B_1, \dots, B_l$  of  $\mathbb{R}$ . Note that cylinder sets of the form  $E_1$  and  $E_2$  generate the  $\sigma$ -algebras  $\sigma\{U_n^W(c): f(1) < c \leq a\}$  and  $\sigma\{U_n^W(c): a + d \leq c < f(0)\}$ , respectively. Now take  $M_n = \frac{1}{4}dn^{1/3} \inf_{u \in (0,1)} |g'(u)|$  and consider the events

$$E'_1 = E_1 \cap \{U_{n, M_n}^W(a) = U_n^W(a)\},$$

$$E'_2 = E_2 \cap \{U_{n, M_n}^W(a + d) = U_n^W(a + d)\},$$

where

$$U_{n, M_n}^W(c) = \operatorname{argmax}\{n^{1/3}|t - g(c)| \leq M_n: W_n(F(t)) + \sqrt{n}(F(t) - ct)\}.$$

By monotonicity of  $U_n^W$  it follows that the event  $E'_1$  depends only on the increments of Brownian motion beyond time  $F(g(a) - n^{-1/3}M_n)$  (note that  $g$  is decreasing) and that the event  $E'_2$  is only dependent on the increments of Brownian motion before time  $F(g(a + d) + n^{-1/3}M_n)$ . By definition of  $M_n$ , it follows that  $E'_1$  and  $E'_2$  are independent. Since for all  $a \in (f(1), f(0))$  we have that  $V_n^W(a) = n^{1/3}(U_n^W(a) - g(a))$ , according to Theorem 3.1,

$$\begin{aligned} & |P(E_1 \cap E_2) - P(E_1)P(E_2)| \\ & \leq 3P\{U_{n, M_n}^W(a) \neq U_n^W(a)\} + 3P\{U_{n, M_n}^W(a + d) \neq U_n^W(a + d)\} \\ & = 3P\{n^{1/3}|U_n^W(a) - g(a)| > M_n\} \\ & \quad + 3P\{n^{1/3}|U_n^W(a + d) - g(a + d)| > M_n\} \\ & \leq 12 \exp(-CM_n^3), \end{aligned}$$

which proves the theorem.  $\square$

Apart from the exponential bound on the mixing function we will need the following two lemmas. The lemmas are analogous to Theorems 17.2.1 and 17.2.2 in Ibragimov and Linnik (1971) and can be proven similarly, since in the quoted Theorems 17.2.1 and 17.2.2 the stationarity is not essential.

LEMMA 3.1. *If  $X$  is measurable with respect to  $\sigma\{U_n^W(c): f(1) < c \leq a\}$  and  $Y$  is measurable with respect to  $\sigma\{U_n^W(c): a + d \leq c < f(0)\}$  ( $d > 0$ ), and if  $|X| \leq C_2, |Y| \leq C_3$  a.s., then*

$$|E(XY) - E(X)E(Y)| \leq 4C_2C_3\alpha_n(d).$$

LEMMA 3.2. *If  $X$  is measurable with respect to  $\sigma\{U_n^W(c): f(1) < c \leq a\}$  and  $Y$  is measurable with respect to  $\sigma\{U_n^W(c): a + d \leq c < f(0)\}$  ( $d > 0$ ), and suppose that for some  $\delta > 0$ ,*

$$E|X|^{2+\delta} \leq C_4, \quad E|Y|^{2+\delta} \leq C_5,$$

then

$$|E(XY) - E(X)E(Y)| \leq C_6(\alpha_n(d))^{\delta/(2+\delta)},$$

where  $C_6 > 0$  only depends on  $C_4$  and  $C_5$ .

In the following, we shall need some properties of the process  $V$ , which are contained in Groeneboom (1989) and Hooghiemstra and Lopuhaä (1998). They are stated in the following lemma.

LEMMA 3.3. *Let  $V(0)$  be defined in (1.3) and for  $b, c \in \mathbb{R}$ , let  $V_b(c)$  be defined by*

$$(3.15) \quad V_b(c) = \operatorname{argmax}_t \{W(t) - b(t - c)^2\}.$$

Then:

- (i)  $V(0)$  has a bounded symmetric density.
- (ii) For  $x \rightarrow \infty, P\{|V(0)| > x\} \sim \lambda x^{-1} \exp(-\frac{2}{3}x^3 - \kappa x)$ , where  $\lambda, \kappa > 0$ .
- (iii) For  $h \downarrow 0, P\{V_b \text{ jumps in } (a - h, a + h)\} \leq \beta_1 h(1 + o(1))$ , where the constant  $\beta_1 > 0$  is independent of  $a$ .

PROOF. (i)–(ii) The first statement follows immediately from the representation for the density of  $V(0)$  given in Groeneboom (1989). The second statement is Lemma 2.1 in Hooghiemstra and Lopuhaä (1998).

(iii) Let  $A_h = \{V \text{ jumps in } [0, h]\}$ . Since the process  $c \mapsto \xi(c)$  is stationary and has jumps at the same points as the process  $c \mapsto V(c)$ , we have that

$$\begin{aligned} P\{V \text{ jumps in } (a - h, a + h)\} &= P\{V \text{ jumps in } (-h, h)\} \\ &\leq 2 \int_{-\infty}^{\infty} P\{A_h | V(0) = x\} f_{V(0)}(x) dx, \end{aligned}$$

where we also use the fact that  $-V(-c) \stackrel{d}{=} V(c)$ . In the proof of Theorem 3.1 in Hooghiemstra and Lopuhaä (1998) it is derived, that

$$\lim_{h \downarrow 0} \frac{P\{A_h | V(0) = x\}}{h} = 2 \int_0^{\infty} \frac{g_1(u + x)}{g_1(x)} up(u) du$$

[see Groeneboom (1989) or Hooghiemstra and Lopuhaä (1998) for the exact

definitions of the functions  $g_1$  and  $p$ ] and moreover that the right-hand side is bounded uniformly in  $x$ . This implies that

$$P\{V \text{ jumps in } (a - h, a + h)\} \leq \beta'_1 h + o(h), \quad h \downarrow 0,$$

where the constant  $\beta'_1$  is independent of  $a$ . By Brownian scaling we have that

$$(3.16) \quad V_b(c) \stackrel{d}{=} b^{-2/3} V(cb^{2/3}),$$

so that

$$P\{V_b \text{ jumps in } (a - h, a + h)\} \leq b^{2/3} \beta'_1 h + o(h), \quad h \downarrow 0,$$

which proves (iii).  $\square$

Leaving the setting of the process  $V$ , it seems intuitively clear that the processes  $V_n^B$  and  $V_n^W$  have the same qualitative behavior and will in particular satisfy a property analogous to Lemma 3.3(iii). This will be proved in the following lemma.

LEMMA 3.4. *Let the interval  $J_n$  be defined by*

$$J_n = \left[ f(1) + n^{-1/3}(\log n)^2, f(0) - n^{-1/3}(\log n)^2 \right].$$

*Then there exists a constant  $\beta_2 > 0$ , independent of  $a \in J_n$ , such that for  $J = B, W$  and for all  $h \in (0, 1)$ ,*

$$P\{V_n^J \text{ jumps in } (a - hn^{-1/3}, a + hn^{-1/3})\} \leq \beta_2 \delta_{n,h} + o(\delta_{n,h})$$

*as  $\delta_{n,h} \downarrow 0$ , where  $\delta_{n,h} = h \vee (n^{-1/3}(\log n)^2)$ .*

PROOF. We first show the statement for  $V_n^W$ . Let  $t_0 = g(a)$ . For notational convenience define for  $|c| \leq 1$ ,

$$V_n^W(a, c) = V_n^W(a + n^{-1/3}c) + n^{1/3}\{g(a + n^{-1/3}c) - g(a)\}.$$

Define the event  $A_n = \{|V_n^W(a, c)| \leq \log n, \text{ for all } |c| \leq 1\}$ . From (3.7) it follows that the process  $c \mapsto V_n^W(a, c)$  is nonincreasing. Therefore,

$$P\{A_n^c\} \leq P\{V_n^W(a, -1) > \log n\} + P\{V_n^W(a, 1) < -\log n\}.$$

Since  $n^{1/3}|g(a \pm n^{-1/3}) - g(a)| \leq \sup_{u \in (0,1)} |g'(u)|$ , it follows from conditions (A1)–(A3) and Theorem 3.1 that  $P\{A_n^c\} = O(\exp(-C(\log n)^3))$ . Hence we can restrict ourselves to  $A_n$ .

In order to transform  $t \mapsto W_n(F(t_0 + n^{-1/3}t))$  into a process  $y \mapsto W_n(F(t_0) + n^{-1/3}y)$ , define  $H_n$  by

$$(3.17) \quad \begin{aligned} H_n(y) &= n^{1/3}\{H(F(t_0) + n^{-1/3}y) - t_0\}, \\ & y \in \left[ -n^{1/3}F(t_0), n^{1/3}(1 - F(t_0)) \right], \end{aligned}$$

where  $H$  is the inverse of  $F$ . Consider the process  $V_n^W$  as defined in (3.5), with  $t$  replaced by  $H_n(y)$ . Then by property (3.7) it follows that

$$V_n^W(a, c) = \sup\{H_n(y) \in [-n^{1/3}t_0, n^{1/3}(1 - t_0)]: \tilde{W}_n(a, y) - p_n(c, y) \text{ is maximal}\},$$

where

$$(3.18) \quad \tilde{W}_n(a, y) = n^{1/6}\{W_n(F(g(a)) + n^{-1/3}y) - W_n(F(g(a)))\}$$

and

$$(3.19) \quad p_n(c, y) = -n^{1/3}y + n^{1/3}(a + n^{-1/3}c)H_n(y).$$

Conditions (A1)–(A3) imply that there exists a constant  $K_1 > 0$ , only depending on  $f$ , such that on  $A_n$  we have

$$|H_n^{-1}(V_n^W(a, c))| \leq K_1 \log n.$$

Suppose that the process  $c \mapsto V_n^W(c)$  jumps in the interval  $(a - hn^{-1/3}, a + hn^{-1/3})$ . Then from (3.8) it follows that the process  $c \mapsto V_n^W(a, c)$  has a jump at some  $c_0 \in (-h, h)$ . This means that if we drop the function  $y \mapsto p_n(c_0, y) + \beta$ , for varying  $\beta \in \mathbb{R}$ , on the process  $y \mapsto \tilde{W}_n(a, y)$ , it first touches  $\tilde{W}_n(a, y)$  simultaneously in two points  $(y_1, w_1)$  and  $(y_2, w_2)$ . Note that on the event  $A_n$ , we have  $|y_1 - y_2| \leq 2K_1 \log n$ . We first show that for each  $y_i, i = 1, 2$ , we can construct a parabola that lies above  $p_n(c_0, y)$  for all  $|y| \leq K_1 \log n$ , and that touches  $p_n(c_0, y)$  at  $(y_i, w_i)$ .

To this end consider the second derivative of  $p_n(c, y)$ . Conditions (A1)–(A3) imply that for  $|c| < 1$ , there exists a constant  $K_2 > 0$ , only depending on  $f$ , such that

$$p_n''(c, y) = \frac{d^2 p_n(c, y)}{dy^2} \leq aH''(F(t_0))\{1 + K_2 n^{-1/3}|1 + y|\}.$$

Choose  $M > K_2$  and define the parabola

$$(3.20) \quad \pi_n(c, y) = ca^{-1}y + \alpha_n y^2,$$

where  $\alpha_n = \frac{1}{2}aH''(F(t_0))\{1 + Mn^{-1/3}(1 + K_1 \log n)\}$ . Then it follows immediately that for all  $|y| \leq K_1 \log n, |c| < 1$  and  $b \in \mathbb{R}$ ,

$$\pi_n''(b, y) > p_n''(c, y).$$

If we choose  $b_1$  such that  $b_1 a^{-1} + 2\alpha_n y_1 = p_n'(c_0, y_1)$ , then  $\pi_n(b_1, y)$  and  $p_n(c_0, y)$  have the same tangent at  $y_1$ . If we also take  $\beta_1 = p_n(c_0, y_1) - \pi_n(b_1, y_1)$ , then it follows that the parabola  $\pi_n(b_1, y) + \beta_1$  lies above  $p_n(c_0, y)$  and touches  $p_n(c_0, y)$  at  $y_1$ . This implies that if we drop  $\pi_n(b_1, y) + \beta$ , for varying  $\beta \in \mathbb{R}$ , on the process  $y \mapsto \tilde{W}_n(a, y)$  it first touches  $\tilde{W}_n(a, y)$  at  $y_1$ . A similar construction holds at  $y_2$  with a suitable choice for  $b_2$  (see Figure 1). Hence if we define

$$V_n^\pi(c) = \sup\{y \in [-n^{1/3}F(t_0), n^{1/3}(1 - F(t_0))]: \tilde{W}_n(a, y) - \pi_n(c, y) \text{ is maximal}\},$$

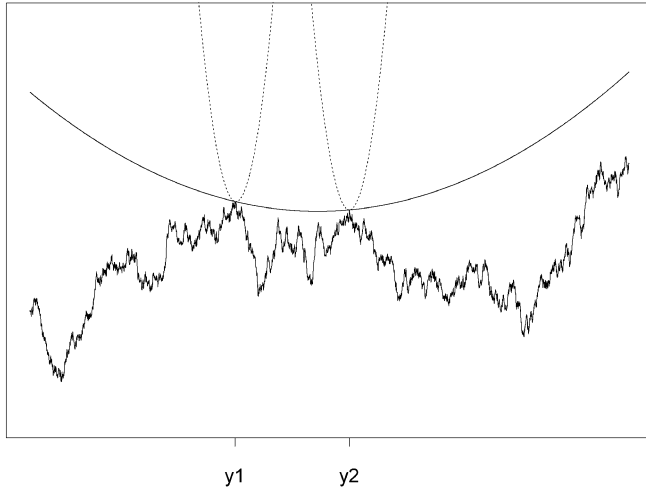

FIG. 1. The function  $p_n(c_0, y)$  (straight line) and parabolas  $\pi_n(b_1, y)$  and  $\pi_n(b_2, y)$  (dotted) touching the process  $y \mapsto \tilde{W}_n(a, y)$  at  $y_1$  and  $y_2$ .

then from the above construction, it follows that the process  $c \mapsto V_n^\pi(c)$  has a jump in the interval  $[b_1, b_2]$  of maximal size  $|y_1 - y_2| \leq 2K_1 \log n$ . Since  $p'_n(c_0, y_i) = \pi'_n(b_i, y_i)$ , for  $i = 1, 2$ , it follows from conditions (A1)–(A3) that there exists a constant  $K_3 > 0$ , only depending on  $f$ , such that

$$|b_i - c_0| \leq K_3 y_i n^{-1/3} \log n, \quad i = 1, 2.$$

Because  $c_0 \in (-h, h)$ , this means that the interval  $[b_1, b_2]$  is contained in

$$I_n = \left( -K_4(h \vee n^{-1/3}(\log n)^2), K_4(h \vee n^{-1/3}(\log n)^2) \right)$$

for some  $K_4 > (1 \vee K_1 K_3)$ . We conclude that, on the event  $A_n$ , we have that if  $c \mapsto V_n^W(c)$  jumps in the interval  $(a - hn^{-1/3}, a + hn^{-1/3})$ , then the process  $c \mapsto V_n^\pi(c)$  jumps in the interval  $I_n$ . However, the process  $y \mapsto \tilde{W}_n(a, y)$  is distributed like Brownian motion  $W$ , so  $V_n^\pi(c)$  is distributed as

$$\sup\{y \in [-n^{1/3}F(t_0), n^{1/3}(1 - F(t_0))]: W(y) - ca^{-1}y - \alpha_n y^2 \text{ is maximal}\}.$$

On the event  $A_n$ , this random variable is only different from

$$V_n(c) = \operatorname{argmax}_{y \in \mathbb{R}} \left\{ W(y) - \alpha_n \left( y + \frac{c}{2\alpha_n} \right)^2 \right\},$$

if  $V_n(c)$  is outside  $[-K_1 \log n, K_1 \log n]$ . Hence

$$\begin{aligned} P\{V_n^\pi \text{ jumps in } I_n, A_n\} &\leq P\{V_n \text{ jumps in } I_n, A_n\} \\ &\quad + P\left\{ \sup_{c \in I_n} |V_n(c)| > K_1 \log n, A_n \right\}. \end{aligned}$$

According to Lemma 3.3, the first probability is of the order  $h \vee (n^{-1/3}(\log n)^2)$ . From the monotonicity of the process  $c \mapsto V_n(c)$ , property (3.16), the stationarity of the process  $c \mapsto \xi(c)$  and Lemma 3.3, it follows that the second probability is of smaller order. This proves the result for  $V_n^W$ .

Turning to the Brownian bridge and the process  $c \mapsto V_n^B(c)$ , for  $|c| \leq 1$  let

$$V_n^B(a, c) = V_n^B(a + n^{-1/3}c) + n^{1/3}\{g(a + n^{-1/3}c) - g(a)\}$$

and

$$\tilde{B}_n(a, y) = n^{1/6}\{B_n(F(g(a)) + n^{-1/3}y) - B_n(F(g(a)))\}.$$

Then

$$V_n^B(a, c)$$

$$= \sup\{H_n(y) \in [-n^{1/3}t_0, n^{1/3}(1 - t_0)]: \tilde{B}_n(a, y) - p_n(c, y) \text{ is maximal}\},$$

where  $p_n(c, y)$  is defined in (3.19). Now define  $\psi_n(c)$  by

$$\psi_n(c) = \sup\{y \in [-n^{1/3}F(t_0), n^{1/3}(1 - F(t_0))]:$$

$$\tilde{B}_n(a, y) - p_n(c - n^{k-1/6}a\xi_n, y) \text{ is maximal}\}.$$

Then  $V_n^B(a, c) = H_n(\psi_n(c + n^{-1/6}a\xi_n))$ . Using (3.4), we have

$$\psi_n(c)$$

$$= \sup\{y \in [-n^{1/3}F(t_0), n^{1/3}(1 - F(t_0))]: \tilde{W}_n(a, y) - q_n(c, y) \text{ is maximal}\},$$

where  $\tilde{W}_n$  is defined in (3.18) and

$$q_n(c, y) = n^{-1/6}\xi_n y - n^{1/3}y + n^{1/3}(a + n^{-1/3}c - n^{-1/2}a\xi_n)H_n(y).$$

Consider the event  $A'_n \cap A''_n$  where

$$A'_n = \{|V_n^B(a, c)| \leq \log n, \text{ for all } c \in (-h, h)\}$$

and

$$A''_n = \{|\xi_n| \leq n^{1/6}/\log n\}.$$

Similar to the event  $A_n$ , we have that  $P\{(A'_n)^c\}$  is of the order  $\exp(-C(\log n)^3)$ . Furthermore,  $P\{(A''_n)^c\} = 2(1 - \Phi(n^{1/6}/\log n))$ , which is of smaller order than  $n^{-1/3}(\log n)^2$ . Hence we can restrict ourselves to the event  $A'_n \cap A''_n$ . Now suppose that  $c \mapsto V_n^B(c)$  jumps in the interval  $(a - hn^{-1/3}, a + hn^{-1/3})$ . This means that the process  $c \mapsto \psi_n(c)$  jumps in the interval  $(-h + n^{-1/6}a\xi_n, h + n^{-1/6}a\xi_n)$ . In that case a completely similar argument as before, involving a comparison of the derivatives of  $q_n(c, y)$  and the parabola  $\pi_n(c, y)$  defined in (3.20), yields that there exists a constant  $K_5 > 0$ , only depending on  $f$ , such that the process  $c \mapsto V_n^\pi(c)$  jumps in the interval

$$I'_n = [-K_5(h \vee n^{-1/3}(\log n)^2), K_5(h \vee n^{-1/3}(\log n)^2)].$$

Hence on the event  $A'_n \cap A''_n$ , it follows that the probability that the process  $c \mapsto V_n^\pi(c)$  has a jump in the interval  $I'_n$ , is bounded by a probability of the order  $h \vee (n^{-1/3}(\log n)^2)$ . The result for  $V_n^B$  now follows.  $\square$

COROLLARY 3.1. *Let  $V_n^E$  be defined as in (3.1) and let  $V_n^B$  be defined as in (3.2). Then*

$$\int_{f(1)}^{f(0)} |V_n^E(a) - V_n^B(a)| da = O_p(n^{-1/3}(\log n)^3).$$

PROOF. Let the empirical process  $E_n$  and the Brownian bridge  $B_n$  be constructed on the same probability space. Then by the Hungarian embedding, we may assume

$$\sup_{t \in [0, 1]} |E_n(t) - B_n(F(t))| = O_p(n^{-1/2} \log n).$$

If  $K_n$  denotes the event  $\{\sup_{t \in [0, 1]} |E_n(t) - B_n(F(t))| \leq n^{-1/2}(\log n)^2\}$ , then  $P\{K_n\} \rightarrow 1$ , as  $n \rightarrow \infty$ . Also let

$$A_n = \{|V_n^E(a)| \leq \log n, |V_n^B(a)| \leq \log n\}$$

and write  $A'_n = K_n \cap A_n$ . Then by Theorem 2.1 and 3.1, we have  $P\{K_n \cap A'_n\} \leq 6 \exp(-C(\log n)^3)$ . Hence, since  $|V_n^E(a) - V_n^B(a)| \leq 2n^{1/3}$ , we have for  $a \in (f(1), f(0))$ ,

$$E|V_n^E(a) - V_n^B(a)|1_{K_n} \leq E|V_n^E(a) - V_n^B(a)|1_{A'_n} + 12n^{1/3} \exp(-C(\log n)^3).$$

Now define  $\varepsilon_n = n^{-1/3}(\log n)^3$  and note that

$$\begin{aligned} E|V_n^E(a) - V_n^B(a)|1_{A'_n} &\leq \int_0^{\varepsilon_n} P\{|V_n^E(a) - V_n^B(a)| > x, A'_n\} dx \\ &\quad + \int_{\varepsilon_n}^{2 \log n} P\{|V_n^E(a) - V_n^B(a)| > x, A'_n\} dx. \end{aligned}$$

The first term on the right-hand side is bounded by  $\varepsilon_n$ . To bound the second probability, consider the process  $t \mapsto Z_n^B(a, t)$  defined by

$$Z_n^B(a, t) = D_n^B(a, t) - n^{1/3}at, \quad t \in [-n^{1/3}g(a), n^{1/3}(1 - g(a))],$$

where  $D_n^B$  is defined in (3.3), and let  $\delta_n = n^{-1/3}(\log n)^2$ . Since  $n^{1/6}|E_n(t) - B_n(F(t))| \leq \delta_n$  on the event  $A'_n$ , we can only have  $|V_n^E(a) - V_n^B(a)| > x$ , if

$$(3.21) \quad |Z_n^B(a, V_n^B(a)) - Z_n^B(a, t)| \leq 2\delta_n,$$

for some  $t \in [-n^{1/3}g(a), n^{1/3}(1 - g(a))]$ , such that  $|t - V_n^B(a)| > x$ .

Consider the line through the points  $(V_n^B(a), D_n^B(a, V_n^B(a)))$  and  $(t, D_n^B(a, t))$ . This line has slope

$$n^{1/3}b = \frac{D_n^B(a, t) - D_n^B(a, V_n^B(a))}{t - V_n^B(a)} = \frac{Z_n^B(a, t) - Z_n^B(a, V_n^B(a))}{t - V_n^B(a)} + n^{1/3}a.$$

Hence it follows that

$$|b - a| \leq 2n^{-1/3} \frac{\delta_n}{x}.$$

This means that if we drop a line with slope  $n^{1/3}b$ , it either first touches the process  $s \mapsto D_n^B(a, s)$  simultaneously in the two (different) points  $t$  and  $V_n^B(a)$ , or in a third point different from both  $t$  and  $V_n^B(a)$ . Property (3.7) implies that the process

$$c \mapsto V_n^B(c) + n^{1/3}(g(c) - g(a))$$

must have a jump in the interval  $I_n(x) = [a - 2n^{-1/3}\delta_n/x, a + 2n^{-1/3}\delta_n/x]$ , and according to property (3.8) this means that the process  $c \mapsto V_n^B(c)$  jumps in the interval  $I_n(x)$ . Hence, we get from Lemma 3.4,

$$\begin{aligned} E|V_n^E(a) - V_n^B(a)|_{A'_n} &\leq \varepsilon_n + \int_{\varepsilon_n}^{2\log n} P\{V_n^B \text{ jumps in } I_n(x), A'_n\} dx \\ &\leq \varepsilon_n + \beta_2 \delta_n \int_{\varepsilon_n}^{2\log n} \left(\frac{2}{x} \vee 1\right) dx = O(n^{-1/3}(\log n)^3), \end{aligned}$$

where the term  $O(n^{-1/3}(\log n)^3)$  is uniform in  $a \in (f(1), f(0))$ . The result now follows from the Markov inequality.  $\square$

The following corollary will enable us to replace  $E|V_n^W(a)| da$  by the asymptotic expectation  $\mu$ , given in Theorem 1.1.

**COROLLARY 3.2.** *Let  $V_n^W$  be defined by (3.5), and let  $\mu$  be defined as in Theorem 1.1. Moreover, let  $V(0)$  be defined by (1.3). Then:*

(i) *For all  $a$  such that*

$$(3.22) \quad n^{1/3}\{F(g(a)) \wedge (1 - F(g(a)))\} \geq \log n,$$

*we have*

$$E|V_n^W(a)| = E|V(0)| \frac{(4a)^{1/3}}{|f'(g(a))|^{2/3}} + O(n^{-1/3}(\log n)^4),$$

*where the term  $O(n^{-1/3}(\log n)^4)$  is uniform in all  $a$ , satisfying (3.22).*

$$(ii) \quad \lim_{n \rightarrow \infty} n^{1/6} \left\{ \int_{f(1)}^{f(0)} E|V_n^W(a)| da - \mu \right\} = 0.$$

**PROOF.** (i) Write  $t_0 = g(a)$ , so that

$$V_n^W(a) = \sup\{t \in [-n^{1/3}t_0, n^{1/3}(1 - t_0)]: Z_n^W(a, t) \text{ is maximal}\},$$

where  $Z_n^W(a, t) = D_n^W(a, t) - n^{1/3}at$ , with  $D_n^W$  as defined in (3.6). Let  $\tilde{V}_n^\pi(a)$  be the argmax defined by

$$\tilde{V}_n^\pi(a) = \sup\{t \in [-n^{1/3}t_0, n^{1/3}(1 - t_0)]: Z_n^\pi(a, t) \text{ is maximal}\}$$

where

$$Z_n^\pi(a, t) = X_n^W(a, t) - n^{2/3} \frac{|f'(g(a))|}{2a^2} (F(g(a) + n^{-1/3}t) - F(g(a)))^2,$$

with  $X_n^W$  as defined in (3.9). It follows immediately that

$$(3.23) \quad \sup_{|t| \leq \log n} |Z_n^W(a, t) - Z_n^\pi(a, t)| \leq \delta_n,$$

where  $\delta_n = K_1 n^{-1/3}(\log n)^3$ , with  $K_1 > 0$  only depending on  $f$ . Let  $A_n$  be the event  $A_n = \{|V_n^\pi(a)| \leq \log n, |V_n^W(a)| \leq \log n\}$ . Since  $P\{|\tilde{V}_n^\pi(a)| > x\} \leq 2 \exp(-Cx^3)$ , which can be seen by using the exponential martingale  $Y_n$  from (3.10) and a stopping time similar to (3.11), it follows, also using Theorem 3.1, that  $P(A_n^c) = O(\exp(-C(\log n)^3))$ . Hence

$$E|V_n^W(a) - \tilde{V}_n^\pi(a)| \leq E|V_n^W(a) - \tilde{V}_n^\pi(a)|1_{A_n} + O(n^{1/3} \exp(-C(\log n)^3)),$$

where the term  $O(n^{1/3} \exp(-C(\log n)^3))$  is uniform in  $a \in (f(1), f(0))$ . Write  $\varepsilon_n = n^{-1/3}(\log n)^4$ , and

$$E|V_n^W(a) - \tilde{V}_n^\pi(a)|1_{A_n} = \int_0^{\varepsilon_n} P\{|V_n^W(a) - \tilde{V}_n^\pi(a)| > x, A_n\} dx + \int_{\varepsilon_n}^{2 \log n} P\{|V_n^W(a) - \tilde{V}_n^\pi(a)| > x, A_n\} dx.$$

The first term on the right-hand side is bounded by  $\varepsilon_n$ . Because (3.23) applies on  $A_n$ , we obtain, using the same argument as used in the proof of Corollary 3.1, that

$$(3.24) \quad \sup_{a \in (f(1), f(0))} |V_n^W(a) - \tilde{V}_n^\pi(a)| = O(n^{-1/3}(\log n)^4).$$

By change of variables  $t = H_n(y)$ , with  $H_n$  defined in (3.17), we have that

$$\tilde{V}_n^\pi(a) = \sup \left\{ H_n(y) \in [-n^{1/3}t_0, n^{1/3}(1 - t_0)]: X_n^W(a, H_n(y)) - \frac{|f'(t_0)|}{2f(t_0)^2}y^2 \text{ is maximal} \right\}.$$

Since  $y \mapsto X_n^W(a, H_n(y))$  is distributed like Brownian motion  $W$ , we find that  $\tilde{V}_n^\pi(a)$  is distributed as  $H_n(V_{n,b})$ , where with  $b = \frac{1}{2}|f'(t_0)|/f(t_0)^2$ ,

$$V_{n,b} = \sup\{y \in [-n^{1/3}F(t_0), n^{1/3}(1 - F(t_0))]: W(y) - by^2 \text{ is maximal}\}.$$

Now consider  $V_b(0)$  as defined in (3.15), and write

$$(3.25) \quad E|H_n(V_{n,b})| = E|H_n(V_b(0))| + E(|H_n(V_{n,b})| - |H_n(V_b(0))|).$$

From conditions (A1)–(A3) and relation (3.16) we find that

$$\begin{aligned} E|H_n(V_b(0))| &= a^{-1}E|V_b(0)| + O(n^{-1/3}) \\ &= E|V(0)| \frac{(4a)^{1/3}}{|f'(g(a))|^{2/3}} + O(n^{-1/3}). \end{aligned}$$

Since  $n^{1/3}\{F(t_0) \wedge (1 - F(t_0))\} \geq \log n$ , the location  $V_{n,b}$  can only be different from  $V_b(0)$  if  $|V_b(0)| > \log n$ . By using (3.16) and Lemma 3.3 we find that

$P\{|V_b(0)| > \log n\} \leq K \exp(-\frac{2}{3}(\log n)^3)$ , where  $K > 0$  only depends on  $f$ . Hence from (3.25) we conclude that

$$E|\tilde{V}_n^\pi(a)| = E|H_n(V_{n,b})| = E|V(0)| \frac{(4a)^{1/3}}{|f'(g(a))|^{2/3}} + O(n^{-1/3}).$$

Together with (3.24) this proves (i).

(ii) This follows immediately from (i), since the values of  $a$  for which (3.22) does not hold only give a contribution of order  $n^{-1/3} \log n$  to the integral

$$\int_{f(1)}^{f(0)} E|V_n^W(a)| da,$$

and since

$$\mu = E|V(0)| \int_{f(1)}^{f(0)} \frac{(4a)^{1/3}}{|f'(g(a))|^{2/3}} da. \quad \square$$

The following result shows that we only have to prove the asymptotic normality result for the process  $V_n^W$ .

**COROLLARY 3.3.** *Let  $V_n^B$  and  $V_n^W$  be defined as by (3.2) and (3.5), respectively. Then*

$$n^{1/6} \int_{f(1)}^{f(0)} (|V_n^B(a)| - |V_n^W(a)|) da = o_p(1).$$

**PROOF.** Let, as before,  $W_n$  and  $B_n$  be linked by (3.4). Consider  $D_n^B$  and  $D_n^W$  as defined in (3.3) and (3.6). Let  $A_n$  be the event

$$A_n = \{|\xi_n| \leq \log n, |V_n^W(a)| \leq \log n, |V_n^B(a)| \leq \log n\}.$$

Then on the event  $A_n$ , for all  $|t| \leq \log n$ , we have  $|D_n^W(a, t) - D_n^B(a, t)| \leq K_1 n^{-1/6} (\log n)^2$ , for some constant  $K_1 > 0$  only depending on  $f$ . By a similar argument as in the proof of Corollaries 3.1 and 3.2, we get

$$(3.26) \quad \sup_{a \in (f(1), f(0))} E|V_n^B(a) - V_n^W(a)| = O(n^{-1/6} (\log n)^3).$$

This shows that in this way we cannot find a sufficiently small bound for the integral  $n^{1/6} \int \{|V_n^B(a) - |V_n^W(a)|\} da$ .

Therefore, for  $a$  belonging to the set

$$J_n = \{a: \text{both } a \text{ and } a(1 - \xi_n n^{-1/2}) \in (f(1), f(0))\},$$

we introduce

$$V_n^B(a, \xi_n) = V_n^B(a - an^{-1/2}\xi_n) + n^{1/3}\{g(a - an^{-1/2}\xi_n) - g(a)\}.$$

By property (3.7) we have that

$$V_n^B(a, \xi_n) = \sup\{t \in [-n^{1/3}t_0, n^{1/3}(1 - t_0)]: Z_n^\xi(a, t) \text{ is maximal}\},$$

where

$$Z_n^\xi(a, t) = Z_n^W(a, t) - n^{1/6}\xi_n\{F(t_0 + n^{-1/3}t) - F(t_0)\} + n^{-1/6}\xi_n f(t_0)t.$$

Let the event  $A'_n$  be defined by

$$A'_n = \{|\xi_n| \leq n^{1/6}, |V_n^W(a)| \leq \log n, |V_n^B(a, \xi_n)| \leq \log n\}.$$

Then on  $A'_n$ , for all  $|t| \leq \log n$  we have that  $|Z_n^W(a, t) - Z_n^\xi(a, t)| \leq K_2 n^{-1/3}(\log n)^2$ , for some constant  $K_2 > 0$  not depending on  $a$ . Again by a similar argument as in the proof of Corollaries 3.1 and 3.2, we get

$$\sup_{a \in J_n} E|V_n^B(a, \xi_n) - V_n^W(a)| = O(n^{-1/3}(\log n)^3),$$

and hence

$$n^{1/6} \int_{a \in J_n} E|V_n^B(a, \xi_n) - V_n^W(a)| da = o(1).$$

From Theorem 3.1 it follows that  $E|V_n^B(a)| = O(1)$  and  $E|V_n^W(a)| = O(1)$  uniformly in  $a \in (f(1), f(0))$ . Hence the contribution of the integrals over  $[f(1), f(0)] \setminus J_n$  is negligible, and it remains to show that

$$(3.27) \quad n^{1/6} \int_{a \in J_n} \{|V_n^B(a, \xi_n)| - |V_n^B(a)|\} da = o_p(1).$$

Note that for the same reason,

$$n^{1/6} \int_{a \in J_n} |V_n^W(a)| da = n^{1/6} \int_{f(1)}^{f(0)} |V_n^W(a)| da + O_p(n^{-1/3}),$$

and that by change of variables we get

$$\begin{aligned} n^{1/6} \int_{a \in J_n} |V_n^B(a, \xi_n)| da &= n^{1/6} \int_{f(1)}^{f(0)} |V_n^B(a) - ag'(a)\xi_n n^{-1/6}| da \\ &\quad + O_p(n^{-1/3}). \end{aligned}$$

Therefore,

$$\begin{aligned} n^{1/6} \int_{a \in J_n} \{|V_n^B(a, \xi_n)| - |V_n^B(a)|\} da \\ = n^{1/6} \int_{f(1)}^{f(0)} \{|V_n^B(a) - ag'(a)\xi_n n^{-1/6}| - |V_n^B(a)|\} da + O_p(n^{-1/3}). \end{aligned}$$

Let  $\varepsilon > 0$ . Then

$$\begin{aligned} n^{1/6} \int_{f(1)}^{f(0)} \{|V_n^B(a) - ag'(a)n^{-1/6}\xi_n| - |V_n^B(a)|\} da \\ = n^{1/6} \int_{f(1)}^{f(0)} \{|V_n^B(a) - ag'(a)n^{-1/6}\xi_n| - |V_n^B(a)|\} \mathbf{1}_{[0, \varepsilon]}(|V_n^B(a)|) da \\ + n^{1/6} \int_{f(1)}^{f(0)} \{|V_n^B(a) - ag'(a)n^{-1/6}\xi_n| - |V_n^B(a)|\} \mathbf{1}_{(\varepsilon, \infty)}(|V_n^B(a)|) da. \end{aligned}$$

We clearly have, using the independence of  $\xi_n$  and  $V_n^B$ , that the expectation of the first term on the right-hand side of (3.28) is bounded above by

$$E|\xi_n| \int_{f(1)}^{f(0)} |ag'(a)| P\{|V_n^B(a)| \leq \varepsilon\} da.$$

According to Theorem 3.2 it follows that  $P\{|V_n^B(a)| \leq \varepsilon\} \rightarrow P\{|\xi(0)| \leq \phi_1(a)\varepsilon\}$ . Hence from Lemma 3.3 and conditions (A1)–(A3) it follows that there exists a  $K_3 > 0$ , such that for any  $\varepsilon > 0$ ,

$$\begin{aligned} & \limsup_{n \rightarrow \infty} En^{1/6} \int_{f(1)}^{f(0)} \|V_n^B(a) - ag'(a)n^{-1/6\xi_n} - |V_n^B(a)|\| \mathbf{1}_{[0, \varepsilon]}(|V_n^B(a)|) da \\ (3.29) \quad & \leq K_3 \varepsilon. \end{aligned}$$

For the second term on the right-hand side of (3.28) we have

$$\begin{aligned} & n^{1/6} \int_{f(1)}^{f(0)} \{|V_n^B(a) - ag'(a)n^{-1/6\xi_n} - |V_n^B(a)|\} \mathbf{1}_{(\varepsilon, \infty)}(|V_n^B(a)|) da \\ & = \int_{f(1)}^{f(0)} \mathbf{1}_{(\varepsilon, \infty)}(|V_n^B(a)|) \frac{-2\xi_n ag'(a)V_n^B(a) + n^{-1/6\xi_n^2}(ag'(a))^2}{|V_n^B(a) - ag'(a)n^{-1/6\xi_n}| + |V_n^B(a)|} da \\ (3.30) \quad & = \int_{f(1)}^{f(0)} \mathbf{1}_{(\varepsilon, \infty)}(|V_n^B(a)|) \frac{-2\xi_n ag'(a)V_n^B(a)}{|V_n^B(a) - ag'(a)n^{-1/6\xi_n}| + |V_n^B(a)|} da \\ & \quad + O_p(n^{-1/6}) \\ & = -n \int_{f(1)}^{f(0)} ag'(a) \text{sign}(V_n^B(a)) \mathbf{1}_{(\varepsilon, \infty)}(|V_n^B(a)|) da + O_p(n^{-1/6}), \end{aligned}$$

using the fact that, for  $|V_n^B(a)| > \varepsilon$ ,

$$\begin{aligned} & \left| \frac{2V_n^B(a)}{|V_n^B(a) - ag'(a)n^{-1/6\xi_n}| + |V_n^B(a)|} - \frac{V_n^B(a)}{|V_n^B(a)|} \right| \\ & \leq \frac{|ag'(a)n^{-1/6\xi_n}|}{\varepsilon} = O_p(n^{-1/6}). \end{aligned}$$

For  $a \in (f(1), f(0))$ , let  $S_n^B(a) = \text{sign}(V_n^B(a))\mathbf{1}_{(\varepsilon, \infty)}(|V_n^B(a)|)$  and similarly, let  $S_n^W(a) = \text{sign}(V_n^W(a))\mathbf{1}_{(\varepsilon, \infty)}(|V_n^W(a)|)$ . Then

$$\begin{aligned} & E \left\{ \xi_n \int_{f(1)}^{f(0)} ag'(a) S_n^B(a) da \right\}^2 \\ & = 2 \int \int_{f(1) < a < b < f(0)} abg'(a)g'(b) ES_n^B(a)S_n^B(b) da db. \end{aligned}$$

Furthermore,

$$\begin{aligned} & |ES_n^B(a)S_n^B(b) - ES_n^W(a)S_n^W(b)| \\ & \leq E|S_n^B(a) - S_n^W(a)| + E|S_n^B(b) - S_n^W(b)|. \end{aligned}$$

Note that for every  $a \in (f(1), f(0))$ ,

$$\begin{aligned} E|S_n^B(a) - S_n^W(a)| & \leq 2P\{|V_n^B(a) - V_n^W(a)| > 2\varepsilon\} \\ & \quad + P\{|V_n^B(a)| \leq \varepsilon\} + P\{|V_n^W(a)| \leq \varepsilon\}. \end{aligned}$$

By using the Markov inequality together with (3.26), the first probability on the right-hand side tends to zero, uniformly in  $a \in (f(1), f(0))$ . According to Theorem 3.2 both  $P\{|V_n^B(a)| \leq \varepsilon\}$  and  $P\{|V_n^W(a)| \leq \varepsilon\}$  tend to  $P\{|\xi(0)| \leq \phi_1(a)\varepsilon\}$ , which is  $O(\varepsilon)$  according to Lemma 3.3 and conditions (A1)–(A3). Hence, there exists a  $K_4 > 0$  such that for any  $\varepsilon > 0$ ,

$$\begin{aligned} & \limsup_{n \rightarrow \infty} E \left\{ \xi_n \int_{f(1)}^{f(0)} ag'(a)S_n^B(a) da \right\}^2 \\ & \leq \limsup_{n \rightarrow \infty} 2 \int \int_{f(1) < a < b < f(0)} abg'(a)g'(b)S_n^W(a)S_n^W(b) da db + K_4\varepsilon. \end{aligned}$$

Finally, write

$$ES_n^W(a)S_n^W(b) = \text{cov}(S_n^W(a), S_n^W(b)) + ES_n^W(a)ES_n^W(b).$$

According to Lemma 3.1 and Theorem 3.3, for every  $f(1) < a < b < f(0)$  we get that

$$|\text{cov}(S_n^W(a), S_n^W(b))| \leq 48 \exp(-C_1n(b - a)) \rightarrow 0.$$

Also for every  $a \in (f(1), f(0))$ , according to Theorem 3.2,

$$\begin{aligned} ES_n^W(a) & = P\{V_n^W(a) > \varepsilon\} - P\{V_n^W(a) < -\varepsilon\} \\ & \rightarrow P\{\xi(0) > \phi_1(a)\varepsilon\} - P\{\xi(0) < -\phi_1(a)\varepsilon\} = 0, \end{aligned}$$

because the distribution of  $\xi(0)$  is symmetric (Lemma 3.3). It follows that there exists a  $K_4 > 0$  such that for any  $\varepsilon > 0$ ,

$$\limsup_{n \rightarrow \infty} E \left\{ \xi_n \int_{f(1)}^{f(0)} ag'(a)S_n^B(a) da \right\}^2 \leq K_4\varepsilon.$$

Together with (3.29) and (3.28), this proves (3.27) and the result follows.  $\square$

**4. Asymptotic normality.** From Section 3 it follows that for proving Theorem 1.1, it suffices to prove that

$$(4.1) \quad T_n^W = n^{1/6} \int_{f(1)}^{f(0)} (|V_n^W(a)| - E|V_n^W(a)|) da$$

is asymptotically normal. We first derive the asymptotic variance of  $T_n^W$ . Theorem 3.2 together with Theorem 3.1, which guarantees the uniform

integrability of the sequence  $V_{n,a}^W(c)$  for  $a$  and  $c$  fixed, imply convergence of moments of  $(V_{n,a}^W(0), V_{n,a}^W(c))$  to the corresponding moments of  $(\xi(0), \xi(c))$ . This leads to the following lemma.

LEMMA 4.1. For  $n \rightarrow \infty$ ,

$$\text{var}\left(n^{1/6} \int_{f(1)}^{f(0)} |V_n^W(a)| da\right) \rightarrow 8 \int_0^\infty \text{cov}(|\xi(0)|, |\xi(c)|) dc.$$

PROOF. We have that

$$\begin{aligned} &\text{var}\left(n^{1/6} \int_{f(1)}^{f(0)} |V_n^W(a)| da\right) \\ &= 2n^{1/3} \int_{f(1)}^{f(0)} \int_a^{f(0)} \text{cov}(|V_n^W(a)|, |V_n^W(b)|) db da \\ &= 8 \int_{f(1)}^{f(0)} ag'(a) \int_0^{n^{1/3}\phi_2(a)^{-1}(a-f(0))} \text{cov}(|V_{n,a}^W(0)|, |V_{n,a}^W(c)|) dc da, \end{aligned}$$

by change of integration variables  $b = a - \phi_2(a)cn^{-1/3}$ . As noted above we have for  $a$  and  $c$  fixed

$$\text{cov}(|V_{n,a}^W(0)|, |V_{n,a}^W(c)|) \rightarrow \text{cov}(|\xi(0)|, |\xi(c)|).$$

Theorem 3.1 and the assumptions (A1)–(A2) also imply that, uniformly in  $n$ ,  $a$  and  $c$ ,

$$E|V_{n,a}^W(0)|^3 \leq C_4 \quad \text{and} \quad E|V_{n,a}^W(c)|^3 \leq C_5.$$

Hence by Lemma 3.2 together with (3.14), it follows that

$$\begin{aligned} |\text{cov}(|V_{n,a}^W(0)|, |V_{n,a}^W(c)|)| &\leq C_6(\alpha_n(|n^{-1/3}\phi_2(a)c|))^{1/3} \\ &\leq D_1 \exp(-D_2|c|^3), \end{aligned}$$

where  $D_1, D_2 > 0$  do not depend on  $n$ ,  $a$  and  $c$ . It follows by dominated convergence that

$$\text{var}\left(n^{1/6} \int_{f(1)}^{f(0)} |V_n^W(a)| da\right) \rightarrow 8 \int_{f(1)}^{f(0)} ag'(a) \int_0^{-\infty} \text{cov}(|\xi(0)|, |\xi(c)|) dc da.$$

Since the process  $c \mapsto \xi(c)$  is stationary.

$$\int_0^{-\infty} \text{cov}(|\xi(0)|, |\xi(c)|) dc = - \int_0^\infty \text{cov}(|\xi(0)|, |\xi(c)|) dc.$$

Furthermore

$$- \int_{f(1)}^{f(0)} ag'(a) da = - \int_1^0 f(x) dx = 1.$$

This proves the lemma.  $\square$

THEOREM 4.1. *Let  $T_n^W$  be defined by (4.1). Then*

$$T_n^W \rightarrow_d \mathcal{N}(0, \sigma^2),$$

where

$$\sigma^2 = 8 \int_0^\infty \text{cov}(|\xi(0)|, |\xi(c)|) dc.$$

PROOF. Define

$$W'_n(a) = |V_n^W(a)| - E|V_n^W(a)|.$$

Let

$$L_n = (f(0) - f(1))n^{-1/3}(\log n)^3,$$

$$M_n = (f(0) - f(1))n^{-1/3} \log n,$$

$$N_n = [(f(0) - f(1))/(L_n + M_n)] = \left\lfloor \frac{n^{1/3}}{\log n + (\log n)^3} \right\rfloor,$$

where  $[x]$  denotes the integer part of  $x$ . We divide the interval  $(f(1), f(0))$  into blocks of alternating lengths

$$A_j = (f(1) + (j - 1)(L_n + M_n), f(1) + (j - 1)(L_n + M_n) + L_n),$$

$$B_j = (f(1) + (j - 1)(L_n + M_n) + L_n, f(1) + j(L_n + M_n)),$$

where  $1 \leq j \leq N_n$ . Now write

$$T'_n = S'_n + S''_n + R_n,$$

where

$$S'_n = n^{1/6} \sum_{j=1}^{N_n} \int_{A_j} W'_n(a) da,$$

$$S''_n = n^{1/6} \sum_{j=1}^{N_n} \int_{B_j} W'_n(a) da,$$

$$R_n = n^{1/6} \int_{f(1)+N_n(L_n+M_n)}^{f(0)} W'_n(a) da.$$

According to Theorem 3.1 and the Cauchy-Schwarz inequality for all  $a, b \in (f(1), f(0))$ ,

$$(4.2) \quad E|W'_n(a)W'_n(b)| < K,$$

where the constant  $K > 0$  is uniformly in  $n, a$  and  $b$ . Together with the fact that

$$f(0) - f(1) - N_n(L_n + M_n) \leq L_n + M_n = O(n^{-1/3}(\log n)^3),$$

this shows that  $ER_n^2 \rightarrow 0$ , and hence  $R_n = o_p(1)$ .

Next we show that the contribution of the small blocks (of length  $M_n$ ) is negligible. To this end consider

$$E(S''_n)^2 = n^{1/3} \sum_{j=1}^{N_n} E \left( \int_{B_j} W'_n(a) da \right)^2 + n^{1/3} \sum_{i \neq j} \int_{B_i} \int_{B_j} EW'_n(a)W'_n(b) da db.$$

We have

$$|EW'_n(a)W'_n(b)| = |\text{cov}(|V_n^W(a)|, |V_n^W(b)|)| \leq D_3 \exp(-D_4 n|b - a|^3),$$

where  $D_3, D_4 > 0$  only depend on  $f$ , by using Lemma 3.2 and (3.14). For  $a \in B_i$  and  $b \in B_j, i \neq j$ , we have that  $|b - a| \geq n^{-1/3}(\log n)^3$ . Since  $N_n \sim n^{1/3}/(\log n)^3$ , this implies that

$$\left| n^{1/3} \sum_{i \neq j} \int_{B_i} \int_{B_j} EW'_n(a)W'_n(b) da db \right| \leq n^{1/3} N_n^2 M_n^2 D_3 \exp(-D_4 (\log n)^9) \rightarrow 0.$$

Hence

$$E(S''_n)^2 = n^{1/3} \sum_{j=1}^{N_n} E \left( \int_{B_j} W'_n(a) da \right)^2 + o(1).$$

Using (4.2) we obtain

$$E(S''_n)^2 = O(n^{1/3} N_n M_n^2) \rightarrow 0$$

and hence that the contribution of the small blocks is negligible.

Put

$$Y_j = n^{1/6} \int_{A_j} W'_n(a) da \quad \text{and} \quad \sigma_n^2 = \text{var} \left( \sum_{j=1}^{N_n} Y_j \right),$$

so that  $S'_n = \sum_{j=1}^{N_n} Y_j$  and  $\sigma_n^2 = \text{var}(S'_n)$ . We have

$$\begin{aligned} & \left| E \exp \left\{ \frac{i u}{\sigma_n} \sum_{j=1}^{N_n} Y_j \right\} - \prod_{j=1}^{N_n} E \exp \left\{ \frac{i u}{\sigma_n} Y_j \right\} \right| \\ & \leq \sum_{k=2}^{N_n} \left| E \exp \left\{ \frac{i u}{\sigma_n} \sum_{j=1}^k Y_j \right\} - E \exp \left\{ \frac{i u}{\sigma_n} \sum_{j=1}^{k-1} Y_j \right\} E \exp \left\{ \frac{i u}{\sigma_n} Y_k \right\} \right| \\ & \leq 4(N_n - 1) \alpha_n(M_n), \end{aligned}$$

where the last inequality follows from Lemma 3.1. Observe that  $N_n \alpha_n(M_n) \rightarrow 0$ , which means that we can in fact apply the central limit theorem to independent copies of  $Y_j$ . The asymptotic normality of  $S'_n$ , hence follows if we show that the contributions of the large blocks,  $Y_j$ , satisfy the Lindeberg condition, that is, for each  $\varepsilon > 0$ ,

$$\frac{1}{\sigma_n^2} \sum_{j=1}^{N_n} E Y_j^2 \mathbf{1}_{\{|Y_j| > \varepsilon \sigma_n\}} \rightarrow 0, \quad n \rightarrow \infty.$$

Note that by the Markov inequality

$$E Y_j^2 \mathbf{1}_{\{|Y_j| > \varepsilon \sigma_n\}} \leq \frac{1}{\varepsilon \sigma_n} E(|Y_j|^3).$$

Again using Cauchy–Schwarz and the uniform boundedness of the moments of  $|W'_n(a)|$  we obtain

$$\sup_{1 \leq j \leq N_n} E(|Y_j|^3) = n^{1/2} O(|A_j|^3) = O(n^{-1/2} (\log n)^9).$$

Hence

$$\frac{1}{\sigma_n^2} \sum_{j=1}^{N_n} EY_j^2 \mathbf{1}_{\{|Y_j| > \varepsilon \sigma_n\}} \leq \frac{1}{\varepsilon \sigma_n^3} N_n \sup_{1 \leq j \leq N_n} E(|Y_j|^3) = O(\sigma_n^{-3} n^{-1/6} (\log n)^6).$$

Note that

$$\sigma_n^2 = \text{var}(S'_n) = \text{var}(T'_n) + \text{var}(S''_n + R_n) - 2ET'_n(S''_n + R_n).$$

Using the obtained limit results for  $E(S''_n)^2$  and  $ER_n^2$  and the inequality of Cauchy–Schwarz, we conclude that

$$\text{var}(S''_n + R_n) = E(S''_n)^2 + ER_n^2 + 2E(S''_n R_n) \rightarrow 0,$$

and that according to Lemma 4.1,

$$ET'_n(S''_n + R_n) \leq \sqrt{E(T'_n)^2 \text{var}(S''_n + R_n)} \rightarrow 0.$$

So we find that

$$\sigma_n^2 = \text{var}(S'_n) = \sigma^2 + o(1),$$

which implies that

$$\frac{1}{\sigma_n^2} \sum_{j=1}^{N_n} EY_j^2 \mathbf{1}_{\{|Y_j| > \varepsilon \sigma_n\}} = O(n^{-1/6} (\log n)^6) \rightarrow 0.$$

This proves the theorem.  $\square$

**Acknowledgments.** We thank Jon Wellner who suggested to use the martingales of Lemma 2.2, leading to the exponential bounds in Section 2. We also thank Vladimir Koulikov and an anonymous referee for their detailed comments.
