HOMOTOPY RIGIDITY OF LINEAR ACTIONS: CHARACTERS TELL ALL

BY ARUNAS LIULEVICIUS¹

Our aim is to present a striking rigidity phenomenom in unitary representations of compact groups. Let U = U(n) be a unitary group and H a closed subgroup of U. The homogeneous space U/H is a smooth manifold with a smooth action λ of U induced by left multiplication. If $\alpha: G \to U$ is a representation of the compact group G, then $\lambda \circ (\alpha \times 1): G \times U/H \to U/H$ is an action of G on U/H, and we denote this G-structure by $(U/H, \alpha)$. Such actions of G on U/H are called *linear* actions. We shall give a complete description of the G-homotopy types of linear actions on U/H for a certain class of H. To motivate our results we shall first examine some obvious G-equivalences of linear actions.

If X is a U-space, then the set of U-maps $Map_{U}(U/H, X)$ is in one-to-one correspondence with elements $x \in X$ such that $U_x \supset H$, where $U_x = \{u \in U\}$ U|ux = x is the isotropy group of the action at x. For example, if $a \in U$ then the element aH in U/H has isotropy group aHa^{-1} and the U-map f: $U/aHa^{-1} \rightarrow U/H$ given by $f(uaHa^{-1}) = uaH$ is a U-equivalence. Indeed if H and K are closed subgroups of U then U/H and U/K are U-equivalent if and only if $K = aHa^{-1}$ for a suitable $a \in U$. Suppose α , $\gamma: G \to U$ are representations such that there exists an $a \in U$ such that $\gamma(g) = a\alpha(g)a^{-1}$ for all $g \in G$ (we say that γ is similar to α). The map $k: (U/H, \alpha) \rightarrow C$ $(U/H, \gamma)$ given by k(uH) = auH is a G-equivalence. Indeed, k is the composition of the G-equivalence $(U/H, \alpha) \rightarrow (U/aHa^{-1}, \gamma)$ induced by conjugation with a in U and the U-equivalence (hence G-equivalence!) f: $(U/aHa^{-1}, \gamma) \rightarrow (U/H, \gamma)$. Thus similarity of representations gives us Gequivalences of the associated linear actions on U/H. Here is another obvious way of obtaining G-equivalences: let $c: U \rightarrow U$ be conjugation by unitary matrices $c(a) = \overline{a}$; then if c(H) = H, we obtain a G-equivalence c: $(U/H, \alpha) \rightarrow (U/H, \overline{\alpha})$ where $\overline{\alpha} = c \circ \alpha$ is the representation conjugate to α .

It is too much to hope that $(U/H, \alpha)$ is G-homotopy equivalent to $(U/H, \beta)$ if and only if β or $\overline{\beta}$ is similar to α . For example, if H is a subgroup of maximal rank in U and C is the center of U then $C \subset H$ and C acts trivially on U/H, so if we let P(U) = U/C be the projective unitary group (with $q: U \to P(U)$ the quotient map), then the standard left action λ of U on U/H induces an action of P(U) on U/H, and it is the similarity class of the projective representation $q \circ \alpha: G \to P(U)$ which matters. We have: if $\alpha, \beta: G \to U$ are representations and $\chi: G \to S^1 = C$ is a homomorphism such that β or $\overline{\beta}$ is similar to $\chi \alpha$ then $(U/H, \alpha)$ is G-equiva-

lent to $(U/H, \beta)$, and indeed through a map which is induced by an *R*-linear map of R^{2n} (the underlying real vector space of the complex vector space C^n on which U = U(n) acts in the standard way). The reader would expect to find more *G*-equivalences of linear actions if we drop linearity, and yet more *G*-homotopy equivalences. The surprise is that if we make a mild restriction on *H* then we find that linear actions of *G* on U/H are *rigid under homotopy*: $(U/H, \alpha)$ is *G*-homotopy equivalent to $(U/H, \beta)$ if and only if they are *G*-equivalent through an *R*-linear map. Here is a sample result:

THEOREM 1 (HOMOTOPY RIGIDITY OF LINEAR ACTIONS). If H is a subgroup of U = U(n) conjugate to $U(n - k) \times T^k$, where T^k is the k-torus and $n \ge 2k$, $\alpha, \beta: G \to U$ representations of a compact group G, then a G-map f: $(U/H, \alpha) \to (U/H, \beta)$ exists with f: $U/H \to U/H$ a homotopy equivalence if and only if there is a linear character $\chi: G \to S^1$ and β or $\overline{\beta}$ is similar to $\chi\alpha$.

We should point out that the condition $n \ge 2k$ is not necessary: for example, homotopy rigidity of linear actions holds for $U(5)/U(2) \times T^3$ and for $U(6)/U(2) \times T^4$, but the proof is much more involved. Similarly, the condition that H be conjugate to $U(n - k) \times T^k$ is too strong: in [13] we show homotopy rigidity of linear actions on $U(m + n + 1)/U(m) \times U(n)$ $\times U(1)$ for $mn \ge m + n + 1$. The right level of generality for our current approach seems to be the following: let us call a subgroup H of U friendly if H is closed, connected, of maximal rank in U = U(n) and there exists a nonzero vector $v \in C^n$ such that $hv = \lambda(h)v$ for some linear character λ : $h \to S^1$; indeed we assume H is conjugate to a subgroup $U(n_1) \times \cdots \times$ $U(n_k) \subset U(n)$ with $n_1 \ge \cdots \ge n_k = 1$ and $n_1 + \cdots + n_k = n$ (see Borel and Siebenthal [7]). We shall outline a strategy for proving

CONJECTURE A. If H is a friendly subgroup of U then linear actions of a compact group G on U/H are rigid under homotopy.

Indeed one can conjecture that linear actions of G are rigid for U/H where H is connected of maximal rank. This is work in progress with Wu-Yi Hsiang.

An immediate consequence of our homotopy rigidity result is that the G-homotopy type of $(U/H, \alpha)$ can be read off from the character table of G (characters tell all). For example, if $\alpha, \beta: G \to U$ are representations and $|\text{Trace } \alpha(g)| \neq |\text{Trace } \beta(g)|$ for some element $g \in G$, then $(U/H, \alpha)$ and $(U/H, \beta)$ have distinct G-homotopy types. An example of such a situation is given by the alternating group on five letters A_5 : let α and β be the distinct irreducible 3-dimensional unitary representations, g = (12345), then

Tr α(g) =
$$\frac{1 + \sqrt{5}}{2}$$
 and Tr β(g) = $\frac{1 - \sqrt{5}}{2}$,

so $(U/H, \alpha)$ and $(U/H, \beta)$ are not A_5 -homotopy equivalent for any friendly subgroup H of U = U(3). Here, of course, there are no nontrivial linear characters and all characters of A_5 take real values, so two linear actions $(U/H, \gamma), (U/H, \delta)$ of A_5 on U/H (with H a friendly subgroup of U) are A_5 -homotopy equivalent if and only if γ is similar to δ . The case of α and β is especially interesting since there is an outer automorphism $\varphi: A_5 \rightarrow A_5$ with $\varphi^*\alpha = \beta$. Even the cyclic group of order two G = Z/2Z gives entertaining examples: if we let 1 denote the trivial representation of G then there exist linear actions $\alpha, \beta, \gamma, \delta$ on CP^n such that $(CP^n, \alpha) \approx (CP^n, \beta)$ but (CP^n, α) + 1) \approx (*CPⁿ*, β + 1), and (*CPⁿ*, γ + 1) \approx (*CPⁿ*, δ + 1) but (*CPⁿ*, γ) \approx (*CPⁿ*, δ), where we have used \approx to indicate Z/2Z-homotopy equivalence.

In Theorem 1, f is not assumed to be a G-homotopy equivalence, that is, although there is a homotopy inverse $f': U/H \rightarrow U/H$, we are not saying that such an f' can be found which is a G-map $f': (U/H, \beta) \rightarrow (U/H, \alpha)$. Indeed, Petrie [15] exhibits a G-space Y, a linear action γ on $U/H = CP^k$ and a G-map h: $Y \rightarrow (CP^k, \gamma)$ which is a homotopy equivalence such that the induced map is equivariant K-theory

$$h^!: K_G(CP^k, \gamma) \to K_G(Y)$$

is not an isomorphism-this means that although h is a homotopy equivalence it is not a G-homotopy equivalence. Our approach is based on the fact that this sort of pathology cannot occur if Y is a complex projective space with a linear action (see [11]): given a G-map $h: (CP^n, \alpha) \to (CP^n, \beta)$ such that h: $CP^n \to CP^n$ is a homotopy equivalence, there exists an R-linear G-equivalence $k: (CP^n, \alpha) \to (CP^n, \beta)$ such that h! = k! (so, in particular, h! is an isomorphism).

This report is organized as follows: in the second section, we present an exact sequence on Picard groups of G-line bundles and popularize some work of Graeme Segal [19] on cohomology of topological groups. In the third section we examine the case $U/H = CP^n$ and show how equivariant K-theory allows us to prove the homotopy rigidity theorem for this case. We also examine the general case of H a friendly subgroup of U and show how a result on cohomology automorphisms of U/H implies the homotopy rigidity theorem. The fourth section is devoted to proving the result on automorphisms of $H^*(U/H, Z)$, where H is as in Theorem 1.

A few words about the background of the problem. There is an extensive literature about G-maps of spheres with linear action: de Rham [16], Atiyah and Tall [5], Lee and Wasserman [10], Meyerhoff and Petrie [14]. The current project is the result of numerous consultations with Ted Petrie. Thanks also go to J. F. Adams, J. Dupont, H. Glover, W.-Y. Hsiang, P. Landrock, I. Madsen, G. Segal, R. Stong and J. Tornehave for their helpful comments.

2. An exact sequence of Picard groups. Let X be a G-space, $\operatorname{Pic}_G(X)$ the set of isomorphism classes of complex G-line bundles over X. We give $\operatorname{Pic}_G(X)$ the structure of a group by using the tensor product of line bundles as multiplication. If X is a CW complex, then $H^1(X;Z) \cong [X, S^1]$ and

$$H^2(X; Z) \cong [X, CP^{\infty}] \cong \operatorname{Pic}_E(X),$$

where $E \subset G$ is the subgroup consisting of the identity element.

THEOREM 2. If X is a nonempty connected G-space and $H^1(X; Z) = 0$ then the following sequence is exact:

$$\operatorname{Pic}_{G}(*) \xrightarrow{c'} \operatorname{Pic}_{G}(X) \xrightarrow{i'} \operatorname{Pic}_{E}(X),$$

where $c: X \rightarrow *$ is the collapsing map onto a point, i: $E \subset G$ the inclusion of the identity subgroup.

PROOF. We shall use the technique of Segal's cohomology of groups [19]: if A is an abelian G-group (G compact, A has the compactly generated

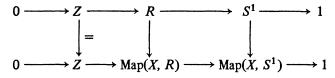

topology) then cohomology groups $H_G^i(A)$ are defined for all $i \ge 0$. The group $H_G^1(A)$ is the quotient of the group of all crossed homomorphisms φ : $G \to A$ (functions which satisfy $\varphi(gg') = \varphi(g) + g \cdot \varphi(g')$ for all g, g' in G) modulo principal crossed homomorphisms (those which have the form $\varphi(g)$ $= g \cdot a - a$ for a fixed a in A). The pleasant thing about Segal's cohomology is that a short exact sequence $0 \to A' \to A \to A'' \to 0$ (meaning that A is a principal A'-bundle with A'' as base) produces a long exact sequence

$$\ldots \to H^i_G(A) \to H^i_G(A'') \xrightarrow{\delta} H^{i+1}_G(A') \to H^{i+1}_G(A) \to \cdots$$

If V is a vector space over R then $H_G^i(V) = 0$ for all i > 0. Given our CW space X we first notice that $H_G^1(\operatorname{Map}(X, S^1))$ is precisely the set of isomorphism classes of $G \times S^1$ -structures on the projection $\pi_1: X \times S^1 \to X$, that is, $H_G^1(\operatorname{Map}(X, S^1)) = \operatorname{Ker} i^!$. Since $H^1(X: Z) = 0$ we obtain an exact sequence

$$0 \rightarrow \operatorname{Map}(X, Z) \rightarrow \operatorname{Map}(X, R) \rightarrow \operatorname{Map}(X, S^{1}) \rightarrow 1,$$

Map(X, Z) = Z since X is connected, and the collapsing map $c: X \to *$ induces a map of exact sequences

which in turn induces maps of long exact sequences of cohomology groups. We have

where $V = \operatorname{Map}(X, R)$ is a vector space over R, so in both exact sequences the extreme terms are zero, hence δ and δ' are isomorphisms; thus c^* : $H^1_G(S^1) \to H^1_G(\operatorname{Map}(X, S^1)) = \operatorname{Ker} i^!$ is an isomorphism, but $H^1_G(S^1) \cong$ $\operatorname{Pic}_G(*) \cong \operatorname{Hom}(G, S^1)$, and under the isomorphism c^* corresponds to $c^!$, so Theorem 2 is proved.

Notice that $\operatorname{Pic}_{E}(Y) \cong H^{2}(Y; Z)$ under the isomorphism which assigns to a line bundle λ its first Chern class $c_{1}(\lambda)$.

COROLLARY 3. Let $f: X \to Y$ be a G-map, X connected, $H^1(X; Z) = 0$, s a G-line bundle over X, t a G-line bundle over Y. Suppose $f^*c_1(i!t) = c_1(i!s)$, then there exists a homomorphism $\chi: G \to S^1$ such that $f!t = \chi s$.

PROOF. Contemplate $s^{-1} \cdot f^{!}t$. We have

$$c_1(i^!(s^{-1} \cdot f^!t)) = -c_1(i^!s) + c_1(i^!f^!t) = -c_1(i^!s) + f^*c_1(i^!t) = 0,$$

so $s^{-1} \cdot f't$ is in the kernel of i', hence in the image of c'-there exists a linear character $\chi: G \to S^1$ with $c'\chi = \chi \cdot 1 = s^{-1} \cdot f't$, or $f't = \chi s$, as claimed.

3. The strategy of proof. Let CP^{n-1} be a complex projective (n-1)dimensional space, $s: S^{2n-1} \to CP^{n-1}$ the Hopf bundle over CP^{n-1} . If $\gamma: G \to U = U(n)$ is a representation, $s = s(\gamma): (S^{2n-1}, \gamma) \to (CP^{n-1}, \gamma)$ defines an element in $\operatorname{Pic}_G(CP^{n-1}, \gamma)$, hence an element in $K_G(CP^{n-1}, \gamma)$ which we still call s. Let $R(G) = K_G(*)$ be the complex representation ring of G, then [3], [18] $K_G(CP^{n-1}, \gamma)$ is a free R(G)-module with $1, \ldots, s^{n-1}$ as basis and

$$s^{n} - \gamma s^{n-1} + (\Lambda^{2} \gamma) s^{n-2} - \cdots + (-1)^{n} \Lambda^{n} \gamma = 0,$$

where $\Lambda^i \gamma$ denotes the *i*th exterior power of γ .

PROPOSITION 4. Let φ : $K_G(CP^{n-1}, \beta) \to K_G(CP^{n-1}, \alpha)$ be a homomorphism of R(G)-algebras with $\varphi(s(\beta)) = \chi s(\alpha)$ for some linear character $\chi: G \to S^1$. Then β is similar to $\chi \alpha$.

PROOF. Let $s(\alpha) = s$, $s(\beta) = t$. Then t satisfies

$$t^n - \beta t^{n-1} + \cdots + (-1)^n \Lambda^n \beta = 0.$$

Hence applying φ we have

$$\chi^n s^n - \beta \chi^{n-1} s^{n-1} + \cdots + (-1)^n \Lambda^n \beta = 0,$$

and multiplying with χ^{-n} we obtain

$$s^n - \beta \chi^{-1} s^{n-1} + \cdots + (-1)^n \Lambda^n (\beta \chi^{-1}) = 0.$$

But

$$s^{n} - \alpha s^{n-1} + \cdots + (-1)^{n} \Lambda^{n} \alpha = 0$$

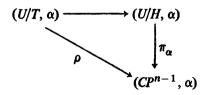

and $K_G(CP^{n-1}, \alpha)$ is R(G)-free on $1, \ldots, s^{n-1}$. Comparing the coefficients of s^{n-1} we obtain $\beta \chi^{-1} = \alpha$ in R(G) as claimed.

We shall now show how homotopy rigidity of linear actions on CP^{n-1} follows (compare [11], [12]). Let $f: (CP^{n-1}, \alpha) \to (CP^{n-1}, \beta)$ be a G-map so that $f^*: H^*(CP^{n-1}; Z) \to H^*(CP^{n-1}; Z)$ is an isomorphism. Let $u = c_1(s) = c_1(i^!s(\alpha))$, the first Chern class of the Hopf bundle s. Then $f^*u = u$ or -usince f^* is an isomorphism and $H^2(CP^{n-1}; Z)$ is generated by u. If $f^*u = -u$, we replace f by $c \circ f$ and β by $\overline{\beta}$ (where c: $CP^{n-1} \to CP^{n-1}$ is induced by conjugation in U = U(n)), so we may assume $f^*u = u$, that is $f^*c_1(i^!t) = c_1(i^!s)$. We apply Corollary 3: there exists a linear character $\chi: G \to S^1$ such that $f^!t = \chi s$. Applying Proposition 4 to $\varphi = f^!$ we obtain that β is similar to $\chi \alpha$. Recalling that we may have had to replace our original β by $\overline{\beta}$ to obtain $f^*u = u$ we obtain the homotopy rigidity result for linear actions on CP^{n-1} .

We build our approach to linear actions on U/H on this special case of CP^{n-1} . Suppose H is a friendly subgroup of U = U(n); there exists a nonzero vector $v \in C^n$ such that $hv = \lambda(h)v$ for all $h \in H$ for some linear character λ . We define a map $\pi: U/H \to CP^{n-1}$ by $\pi(uH) = [uv]$. If $\alpha: G \to U$ is a representation then π is a G-map $\pi_{\alpha}: (U/H, \alpha) \to (CP^{n-1}, \alpha)$.

PROPOSITION 5. If H is a friendly subgroup of U = U(n) and π_{α} is as above, then $\pi_{\alpha}^{!}$: $K_{G}(CP^{n-1}, \alpha) \rightarrow K_{G}(U/H, \alpha)$ is a monomorphism.

PROOF. We may as well assume $H = U(n_1) \times U(n_2) \times \cdots \times U(n_k)$ with $n_k = 1$ and $v = \varepsilon_n$, the last vector in the standard basis of C^n , then π is induced by the inclusion $H \subset U(n-1) \times U(1)$. Let $T = U(1) \times \cdots \times U(1)$ be the standard *n*-torus of U consisting of diagonal matrices, then $T \subset H \subset U$ induces a commutative diagram of projections

and since $\rho^!$ is a monomorphism (see [18]), so is $\pi_{\alpha}^!$.

Now let $\alpha, \beta: G \to U$ be representations, $s = s(\alpha)$, $t = s(\beta)$ the G-Hopf bundles on (CP^{n-1}, α) and (CP^{n-1}, β) , respectively. Let $f: (U/H, \alpha) \to (U/H, \beta)$ be a G-map such that $f: U/H \to U/H$ is a homotopy equivalence. Let $u = c_1(i^{\dagger}\pi_{\alpha}^{!}s) = c_1(i^{\dagger}\pi_{\beta}^{!}t)$. If $f^*u = u$, then as before Corollary 3 says that there exists a linear character $\chi: G \to S^1$ such that $f^{\dagger}\pi_{\beta}^{!}t = \chi\pi_{\alpha}^{!}s = \pi_{\alpha}^{!}(\chi s)$. Thus $f^{!}$ maps the image of $\pi_{\beta}^{!}$ into the image of $\pi_{\alpha}^{!}$. Since $\pi_{\alpha}^{!}$ is a monomorphism, we may define

$$\varphi = \left(\pi_{\alpha}^{!}\right)^{-1} f^{!} \pi_{\beta}^{!} \colon K_{G}\left(CP^{n-1}, \beta\right) \to K_{G}\left(CP^{n-1}, \alpha\right)$$

which, of course, is a map of R(G)-algebras and $\varphi(t) = \chi s$, so Proposition 4 says that β is similar to $\chi \alpha$. The catch, of course, is that there is no reason to expect that f^*u is equal to u, so we have to do more work.

The group of U-maps $\operatorname{Map}_U(U/H, U/H)$ is isomorphic to $N_U(H)/H$, where $N_U(H) = \{a \in U | aHa^{-1} = H\}$ is the normalizer of H in U (see Bredon [8], Samelson [17]). If $\gamma: G \to U$ is a representation and $k: U/H \to$ U/H is a U-map, then $k: (U/H, \gamma) \to (U/H, \gamma)$ is a G-map. Let $c: U \to U$ be given by $c(u) = \overline{u}$, the matrix with complex conjugate entries. We have chosen H in its conjugacy class so that c(H) = H, hence $c: (U/H, \gamma) \to$ $(U/H, \overline{\gamma})$ is a G-map. We have a homomorphism

$$\psi: N_U(H)/H \times Z/2Z \rightarrow \operatorname{Aut}(H^*(U/H; Z))$$

given by $\psi(k, t) = k^* \circ c^{t*}$. Stated in another way: the homomorphism ψ defines an action of $N_U(H)/H \times Z/2Z$ on $H^*(U/H; Z)$. Of course the group Homeq(U/H) of all homotopy classes of homotopy equivalences of U/H also acts on $H^*(U/H; Z)$ by taking induced homomorphisms in cohomology. We now state several related conjectures.

CONJECTURE B. Let H be a friendly subgroup of U = U(n), $\pi: U/H \rightarrow CP^{n-1}$ the standard map, $u = \pi^* c_1(s)$, where s is the Hopf bundle on CP^{n-1} , then the orbit of u under $N_U(H)/H \times Z/2Z$ is the same as the orbit of u under Homeq(U/H).

PROPOSITION 6. Conjecture B implies Theorem 1 (homotopy rigidity of linear actions on U/H).

PROOF. We keep the notation of our earlier discussion: let α , β : $G \rightarrow U = U(n)$ be representations, $f: (U/H, \alpha) \rightarrow (U/H, \beta)$ a G-map such that f:

 $U/H \rightarrow U/H$ is a homotopy equivalence, $u = \pi^* c_1(s)$. According to Conjecture B there exists an element k of $N_U(H)/H \times Z/2Z$ such that $k^*f^*u = u$. Replace f by $f \circ k$ (here we may have to replace α by $\overline{\alpha}$ if conjugation is involved). Then $f^*u = u$, so $i'f'\pi_{\beta}t = i'\pi_{\alpha}^!s$, and since U/H is connected and simply connected, we obtain from Corollary 3 a linear character $\chi: G \rightarrow S^1$ such that $f'\pi_{\beta}t = \chi\pi_{\alpha}^!(s)$. So now letting $\varphi = \pi_{\alpha}^{!-1}f'\pi_{\beta}$ we can apply Proposition 4 to conclude that β is similar to $\chi\alpha$.

We shall prove an even stronger result for a multitude of subgroups of U:

CONJECTURE C. The map ψ is an isomorphism of $N_U(H)/H \times Z/2Z$ onto the group of all algebra isomorphisms of $H^*(U/H; Z)$ if H is a friendly subgroup of U = U(n) and $n \ge 3$.

Notice that $U(2)/T^2 \approx S^2$, and in this case ψ has a cyclic group or order 2 as a kernel. If $n \ge 3$, ψ is a monomorphism.

Let us boldly walk even further on the limb: the following algebraic conjecture implies Conjecture B (and Conjecture C in a lot of cases).

CONJECTURE D. Let T be the standard torus of U = U(n), $\{\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n\}$ the standard basis for C^n , let $\pi_i: U/T \to CP^{n-1}$ for $i = 1, \ldots, n$ be given by $\pi_i(uT) = [u\varepsilon_i]$, s the Hopf bundle on CP^{n-1} , let $x_i = \pi_i^* c_1(s)$. If $x \in H^2(U/T; Z)$ and $x^n = 0$ then there exists an integer a and an i in $\{1, 2, \ldots, n\}$ such that $x = ax_i$.

The algebraic data are easy to state: $H^*(U/T; Z) = Z[x_1, \ldots, x_{n-1}]$ modulo the ideal $I_n = (h_2, \ldots, h_n)$, where h_i is the sum of all monomials of degree *i* in x_1, \ldots, x_{n-1} (see Borel [6])-for example, for n = 4, $h_2 = x_1^2 + x_1x_2 + x_1x_3 + x_2^2 + x_2x_3 + x_3^2$. It is important to notice that n - 1 appears above, not *n*-indeed $x_n = -x_1 - x_2 - \cdots - x_{n-1}$. The group $N_U(T)/T$ is S_n , the symmetric group on *n* letters which acts on $H^*(U/T; Z)$ by permuting the x_1, \ldots, x_n . Conjecture D is trivial to prove for n = 3. For n = 4, the algebra is already delightfully complicated and a hint is helpful: examine the solutions of $x^4 = 0$ first over Z/3Z and then exploit the fact that multiplication by x_1 from $H^6(U(4)/T^4; Z/3Z)$ to $H^8(U(4)/T^4; Z/3Z)$ has kernel of dimension one to show that if $x_1 + y$ is a solution of $x^4 = 0$ over Z and $y = bx_2 + cx_3$ then for all natural numbers k we have $3^k | y$ implies $3^{k+1} | y$, so y = 0.

The limb is beginning to creak ominously, but let's take one more step:

CONJECTURE E. If H is a connected subgroup of maximal rank of U = U(n) and Homeq(U/H) is the group of homotopy classes of homotopy equivalences of U/H then $N_U(H)/H \times Z/2Z$ is a normal subgroup of Homeq(U/H) if $n \ge 3$.

One reason for thinking wishfully about Conjecture E is that it would give a beautifully simple proof of Conjecture C for H = T, the maximal torus of U(n) and Homeq(U/H) is the group of homotopy classes of homotopy equivalences of U/H then $N_U(H)/H \times Z/2Z$ is a normal subgroup of Homeq(U/H) if $n \ge 3$.

4. Algebra automorphisms of $H^*(U/H; Z)$. We shall prove Conjecture C for U = U(n), $H = U(n - k) \times T^k$, $n \ge \max\{2k, k + 2\}$. As before, let $\{\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n\}$ be the standard basis of C^n and let $\pi_i: U/H \to CP^{n-1}$ be the projection $\pi_i(uH) = [u\varepsilon_{n-k+i}]$ for $i = 1, \ldots, k$. Let $y \in H^2(CP^{n-1}; Z)$ be the Chern class of the Hopf bundle and let $x_i = \pi_i^*(y)$; then $H^*(U/H;$

Z) = $Z[x_1, \ldots, x_k]/I$, where the ideal $I = (h_{n-k+1}, \ldots, h_n)$ and h_j is the sum of all monomials of degree j in x_1, \ldots, x_k . A free basis for H^* is given by $x^E = x_1^{e_1} x_2^{e_2} \ldots x_k^{e_k}$, where $0 \le e_i < n - k + i$ (see Borel [6]). The group $N_U(H)/H$ is S_k , the symmetric group on k letters, and it acts on $H^*(U/H; Z)$ by permuting x_1, \ldots, x_k . We examine the case of k = 2 more closely.

LEMMA 7. If $u = ax_1 + bx_2$ is an element in $H^2(U(m+2)/U(m) \times T^2; Z)$ with $u^{2m} = 0$, then either a = 0 or b = 0.

PROOF. We first claim that if both a and b are nonzero and $u^{2m+1} = 0$ then a = b. Notice that $x_1^{m+2} = x_2^{m+2} = 0$ (since both come from CP^{m+1}) and H^{4m+2} has $x_1^m x_2^{m+1}$ as basis. Moreover, $x_1^{m+1} x_2^m = -x_1^m x_2^{m+1}$. We have

$$0 = u^{2m+1} = (ax_1 + bx_2)^{2m+1}$$

= $\binom{2m+1}{m+1} a^{m+1} b^m x_1^{m+1} x_2^m + \binom{2m+1}{m} a^m b^{m+1} x_1^m x_2^{m+1},$

so $a \neq 0, b \neq 0$ implies a = b. If now, in addition, $u^{2m} = 0$, then we have

$$0 = {\binom{2m}{m+1}} a^{2m} x_1^{m+1} x_2^{m-1} + {\binom{2m}{m}} a^{2m} x_1^m x_2^m + {\binom{2m}{m-1}} a^{2m} x_1^{m-1} x_2^{m+1},$$

but H^{4m} has $\{x_1^m x_2^m, x_1^{m-1} x_2^{m+1}\}$ as basis and

$$x_1^{m+1}x_2^{m-1} = -x_1^m x_2^m - x_1^{m-1}x_2^{m+1},$$

so the above sum reduces to

$$0 = \left\{ \begin{pmatrix} 2m \\ m \end{pmatrix} - \begin{pmatrix} 2m \\ m+1 \end{pmatrix} \right\} a^{2m} x_1^m x_2^m,$$

so since $\binom{2m}{m} \neq \binom{2m}{m+1}$ for all *m* it follows that a = 0, a contradiction to our temporary hypothesis that $a \neq 0$ and $b \neq 0$.

COROLLARY 8. Let $v \in H^2(U(m + k)/U(m) \times T^k; Z)$ be an element such that $v^{m+k} = 0$. If $m \ge k$ then $v = ax_i$ for some i in $\{1, \ldots, k\}$.

PROOF. By applying a suitable element of S_k we can assume that the coefficient of x_1 is nonzero. We wish to show that the coefficient of x_i for $i \neq 1$ is zero-and, of course, it is sufficient to prove this for i = 2. Consider the standard map

$$j: U(m+2)/U(m) \times T^2 \to U(m+k)/U(m) \times T^k$$

induced by the standard inclusion $C^{m+2} \subset C^{m+k}$ under which $j^*x_1 = x_1$, $j^*x_2 = x_2, j^*x_i = 0$ for i > 2. Inspect $u = j^*v$; then $u^{m+k} = 0, m+k \le 2m$; hence $a \ne 0$ implies that the coefficient of x_2 is zero.

We are now ready to prove Conjecture C for $U(m + k)/U(m) \times T^k$.

THEOREM 9. If $n \ge \max\{2k, k+2\}$, U = U(n), $H = U(n-k) \times T$, then the map ψ is an isomorphism of $N_U(H)/H \times Z/2Z$ onto the group of all algebra isomorphisms of $H^*(U/H; Z)$.

PROOF. We first prove that ψ is onto. Let φ : $H^*(U/H; Z) \rightarrow H^*(U/H; Z)$

be an algebra automorphism; then $\varphi(x_1) = u$ is an element with $u^n = 0$ (this since $x_1^n = 0$) and because $n \ge 2k$, Corollary 8 is applicable, so $u = ax_i$ for some *i* and a = 1 or -1. By using elements of $N_U(H)/H = S_k$ we can normalize φ (using c^* if necessary) to have $\varphi(x_1) = x_1$. We claim φ is the identity. If not, use S_k to arrange $\varphi(x_2) = -x_2$. Now consider φ as an automorphism of $Z[x_1, \ldots, x_k]$ (remember: there are no relations among the generators in H^2). The relations in grading 2n - 2k + 2 are generated by h_{n-k+1} so we must have $\varphi h_{n-k+1} = \pm h_{n-k+1}$, but $\varphi(x_1^{n-k+1}) = x_1^{n-k+1}$ and $\varphi(x_1^{n-k}x_2) = -x_1^{n-k}x_2$, so $\varphi(x_2) = -x_2$ is impossible, and we have shown that ψ is onto.

To prove that ψ is one-to-one is even easier: since $m \ge 2$ each $\sigma \in N_U(H)/H = S_k$ maps x_1 into some x_i , $c^*x_1 = -x_1$, so the kernel of ψ is contained in $S_k \times 0$, but we have already noticed that $\psi|S_k \times 0$ is faithful, so ψ is one-to-one, as claimed.
