# TWO EXAMPLES OF STOCHASTIC FIELD THEORIES 

Rémi LÉANDRE

(Received September 5, 2003)

#### Abstract

We give some regularization in order to define rigorously a stochastic W.Z.N.W. model or a stochastic Chern-Simons theory. We show that the Markov property of the random field allows us to satisfy the glueing axiom of field theory (of Segal or Atiyah).

## I. Introduction

This list of axioms of a $d$-dimensional field theory is strongly inspired of Segal's axiom of conformal field theory ([50]) and Atiyah's axiom of topological field theory ([5]).

Axioms. a $d$-dimensional field theory is given by the following data:
i) To any $d-1$ Riemannian manifold $(\Sigma, g)$, we associate an Hilbert space $H(\Sigma, g)$ such that $H\left(\Sigma_{1} \cup \Sigma_{2}, g_{1} \cup g_{2}\right)=H\left(\Sigma_{1}, g_{1}\right) \otimes H\left(\Sigma_{2}, g_{2}\right)$ if $\Sigma_{1} \cap \Sigma_{2}=\emptyset$.
ii) If $\left(V, g_{V}\right)$ is a bordism from $\left(\Sigma_{1}, g_{1}\right)$ to $\left(\Sigma_{2}, g_{2}\right)$ such that in a neighborhood of $\Sigma_{2},\left(V, g_{V}\right)$ is isometric to ( $\left[0,1 / 2\left[\times \Sigma_{2}, d t \otimes g_{1}\right)\right.$ and such that in a neighborhood of $\Sigma_{1},\left(U, g_{U}\right)$ is isometric to (] $\left.\left.1 / 2,1\right] \times \Sigma_{1}, d t \otimes g_{1}\right)$, then $\left(U, g_{U}\right)$ realizes a bounded linear map $H\left(V, g_{V}\right)$ from $H\left(\Sigma_{1}, g_{1}\right)$ into $H\left(\Sigma_{2}, g_{2}\right)$.
iii) These data have to satisfy the following requirement (Gluing property): let $\left(V_{1}, g_{V_{1}}\right)$ a bordism from ( $\Sigma_{1}, g_{1}$ ) into ( $\Sigma_{2}, g_{2}$ ) and ( $V_{2}, g_{V_{2}}$ ) be a bordism between $\left(\Sigma_{2}, g_{2}\right)$ into $\left(\Sigma_{3}, g_{3}\right)$. Let ( $W, g_{W}$ ) the Riemannian manifold got by sewing $V_{1}$ and $V_{2}$ along their common boundary $\Sigma_{2}$. Then

$$
\begin{equation*}
H\left(W, g_{W}\right)=H\left(V_{2}, g_{V_{2}}\right) \circ H\left(V_{1}, g_{V_{1}}\right) \tag{1.1}
\end{equation*}
$$

Let us remark that there are some difference with the traditional axioms of field theory:
-) The operator $H\left(V, g_{V}\right)$ is supposed only bounded and not Hilbert-Schmidt as it is traditional.
-) In the gluing axiom, we sew ( $V_{1}, g_{V_{1}}$ ) and ( $V_{2}, g_{V_{2}}$ ) along a piece of the output boundary of $V_{1}$ and a piece of the input boundary of $V_{2}$.

We are motivated in this work by a stochastic realization of these axioms, with in addition a technical modification.

The first example is involved with the stochastic Wess-Zumino-Novikov-Witten model (see [17], [18], [19] for a pedagogical introduction about the physicist model). This is a 2-dimensional field theory. This theory uses infinite dimensional processes over infinite dimensional manifolds. The construction of such processes was pioneered by Kuo ([30]) who has constructed the Brownian motion on infinite dimensional manifold. The Russian school ([6], [12], [7]) has a different way to construct processes on infinite dimensional manifolds. [2] and [13] have constructed the Ornstein-Uhlenbeck process on the loop space by using Dirichlet forms. [1] have constructed the heatkernel measure over a loop group by using the Brownian motion on a loop group. Our construction is related to this work and to the construction of diffusion processes on M-2 Banach manifolds of Brzezniak-Elworthy ([8]). Related works are the papers of Brzezniak-Léandre ([9], [10]) and Léandre ([31], [32], [33], [34], [35], [36], [37], [38], [39], [40], [41]). As in [37] and in [38], our random fields are $C^{k}$. This leads to a simplification with the treatment of [33] for instance: namely no construction of stochastic integrals is required in the treatment of the Wess-Zumino term.

The second example is the 3-dimensional stochastic Chern-Simons theory. Unlike the traditional Chern-Simons theory, our stochastic Chern-Simons theory is not a topological field theory, because we average the connections under a Gaussian measure, instead of the Lebesgue measure as it is classical in Chern-Simons theory ([5], [3], [53]).

In these two examples, we deduce from the gluing property a relation with operads by chosing bordism between always the same connected ( $\Sigma, g$ ) and as exit boundary a finite disjoint union of the same $(\Sigma, g)$. This relation was pioneered for conformal field theory by Huang-Lepowsky ([23]) and Kimura-Stasheff-Voronov ([26]).

The geometrical data of this paper are taken from the work of Freed ([16]).

## II. Stochastic Wess-Zumino-Novikov-Witten model

Let us consider the case of a two dimensional field theory. $V$ is a Riemannian surface with exit and input boudary loops endowed with the canonical metric on $S^{1}$ on each on the connected components of the boundary.

Let us consider $\bar{V}$ got from $V$ by sewing disk along the boudaries. $\bar{V}$ has a canonical metric, inherited from $V$. Let $\Delta_{\bar{V}}$ be the Laplace Beltrami operator on $\bar{V}$. Let $H_{\bar{V}}$ the Hilbert space of maps $f$ from $\bar{V}$ into $R$ such that:

$$
\begin{equation*}
\int_{\bar{V}}\left(\Delta_{\bar{V}}^{k}+1\right) f(z)\left(\Delta_{\bar{V}}^{k}+1\right) f(z) d m_{\bar{V}}(z)<\infty \tag{2.1}
\end{equation*}
$$

where $d m_{\bar{V}}(z)$ denotes the Riemannian measure on $\bar{V}$.
Let $B_{\bar{V}, t}$ be the Brownian motion with values in $H_{\bar{V}}$. It has reproducing Hilbert
space:

$$
\begin{equation*}
\int_{[0,1]} \int_{\bar{V}} \frac{\partial}{\partial t}\left(\Delta_{\bar{V}}^{k}+1\right) f(t, z) \frac{\partial}{\partial t}\left(\Delta_{\bar{V}}^{k}+1\right) f(t, z) d t d m_{\bar{V}}(z)<\infty \tag{2.2}
\end{equation*}
$$

with initial condition $f(0, z)=0$. If $k$ is big enough independent from $r,(t, z) \rightarrow$ $B_{\bar{V}, t}(z)$ is continous in $t \in[0,1]$ and $C^{r}$ in $z \in \bar{V}$ (see [37]).

Let $\bar{S}_{1}=[0,1] \times S_{1}$ where we sew disk along the boundary. $\bar{S}_{1}$ inherites a canonical Riemannian structure. Let $H_{\bar{S}_{1}}$ be the Hilbert space of maps from $\bar{S}_{1}$ into $R$ such that

$$
\begin{equation*}
\int_{\bar{S}_{1}}\left(\Delta_{\bar{S}_{1}}^{k}+I\right) f(z)\left(\Delta_{\bar{S}_{1}}^{k}+1\right) f(z) d m_{\bar{S}_{1}}(z)<\infty \tag{2.3}
\end{equation*}
$$

Let $B_{\bar{S}_{1}, t}$ be the Brownian motion with values in $H_{\bar{S}_{1}}$. It has as reproducing Hilbert space the set of maps $f$ from $[0,1] \times \bar{S}_{1}$ into $R$ such that:

$$
\begin{equation*}
\int_{[0,1]} \int_{\bar{S}_{1}} \frac{\partial}{\partial t}\left(\Delta_{\bar{S}_{1}}^{k}+1\right) f(t, z) \frac{\partial}{\partial t}\left(\Delta_{\bar{S}_{1}}^{k}+1\right) f(t, z) d t d m_{\bar{S}_{1}}(z)<\infty \tag{2.4}
\end{equation*}
$$

with initial condition $f(0, z)=0\left(\Delta_{\bar{S}_{1}}\right.$ denotes the Laplace-Beltrami operator on $\left.\bar{S}_{1}\right)$.
Let $g_{V}(z)$ be a map from $V$ into $[0,1]$ equal to 1 on $V$ where we have removed the output collars [ $0,1 / 2\left[\times \Sigma_{2}\right.$ and where we have removed the input collars $\left.] 1 / 2 ; 1\right] \times$ $\Sigma_{1}$. We suppose that $g_{V}$ is equal to zero on a neighborhood of the boundaries of $V$.

Let $g^{\text {out }}$ be a smooth map from $[0,1 / 2]$ into $[0,1]$ equal to 0 only in 0 and equal to 1 in a neighborhood of $1 / 2$. Let $g^{i n}$ be a smooth map from $[1 / 2,1]$ equal to 0 only in 1 and equal to 1 in a neighborhood of $1 / 2$.

We consider the Gaussian random field parametrized by $U \times[0,1]$ :

$$
\begin{equation*}
B_{V, .,}(.)=g_{V}(.) B_{\bar{V}, .}(.)+\sum_{\text {in }} g^{\text {in }} B_{\bar{S}_{1}, .}^{\text {in }}(.)+\sum_{\text {out }} g^{\text {out }} B_{\bar{S}_{1}, .}^{\text {out }}(.) \tag{2.5}
\end{equation*}
$$

where we take independent Brownian motion on $H_{\bar{S}_{1}}$ which are independent of the Brownian motion $B_{\bar{V}}$. We have a body process and some boundary processes which are independent themselves and of the body process.

An object $V_{\text {tot }, k}=\left(V_{1} \cup V_{2} . . \cup V_{k}\right)$ is constructed inductively as follows: $V_{1}$ is a Riemann surface constructed as before. $V_{\text {tot }, k+1}$ is constructed from $V_{t o t, k}$ where we sew some exit boundaries of $V_{\text {tot }, k}$ along some input boundaries of $V_{k+1}$. Let us remark that in the present theory, we don't consider $V_{\text {tot }, k}$ as a Riemannian manifold, but as the sequence ( $V_{1}, \ldots, V_{k}$ ) and the way we sew $V_{k+1}$ to $V_{\text {tot, } k}$ inductively. Namely, if we consider the random fields parametrized by $V_{t o t, k} \times[0,1]$ considered as a global Riemannian manifold done by (2.5), it is different from the random field $B_{V_{\text {tot,k }}}$ constructed as below. In particular, the sewing collars in $V_{\text {tot }, k}$ are independent in the construction below, and are not independent in the construction (2.5).

We can construct inductively $B_{V_{\text {tot }, k+1}}$ as follows: if $k=1$, it is $B_{V} \cdot B_{V_{k+1}}$ is constructed from Brownian motion independent of those which have constructed $B_{V_{\text {tot }, k}}$, except for the Brownian motions in the input boundaries of $B_{V_{k+1}}$ which coincide with the Brownian motion in the output boundaries of $V_{t o t, k}$ which are sewed to the corresponding input boundaries of $V_{k+1}$. By this procedure, if $z \in V_{t o t}$, we get a process $(t, z) \rightarrow B_{V_{t o t}, t}(z)$ which is continuous in $t$ and $C^{r}$ in $z \in V_{t o t}$.

Let $G$ be a compact simply connected Lie group. We consider Airault-Malliavin equation ([1])

$$
\begin{equation*}
d_{t} g_{V_{t o t}, t}(z)=g_{V_{t o t}, t}(z) \sum e_{i} d_{t} B_{V_{t o t}}^{i}(z) \tag{2.6}
\end{equation*}
$$

starting from $e . B_{V_{\text {tot }}}^{i}$ are independent copies of $B_{V_{\text {tot }}}$ and $e_{i}$ an orthogonal basis of the Lie algebra of $G$.

Let us remark that we can construct the formal action driving the non-linear Random field $g_{V_{t o t}}$ by using large deviation theory ([19], [31]). $t \rightarrow B_{V_{t o t}, t}($.$) is a Brownian$ motion on a Hilbert space whose reproducing kernel $\|\cdot\|$ is deduced from (2.1), (2.3) and (2.5). It has formally the Gaussian law:

$$
\begin{equation*}
d \mu=\frac{1}{Z} \exp \left[-\int_{0}^{1} \frac{1}{2} \frac{\partial}{\partial t}\left\|h_{t}(.)\right\|^{2}\right] d D(h) \tag{2.7}
\end{equation*}
$$

where $d D(h)$ is the formal Lebesgue measure on fields parametrized by $V_{\text {tot }} \times[0,1]$ into $\operatorname{Lie}(G)$. Let us consider the equation

$$
\begin{equation*}
d_{t} g_{V_{t o t}, t, \epsilon}(z)=\epsilon g_{V_{t o t}, t, \epsilon}(z) \sum e_{i} d_{t} B_{V_{t o t}, t}^{i}(z) \tag{2.8}
\end{equation*}
$$

The following large deviation estimate holds: let us consider a borelian subset $O$ on the space of maps from $V_{\text {tot }} \times[0,1]$ into $G$ for the uniform topology. int $O$ denotes its interior for the uniform topology and clos 0 its adherence for the uniform topology. We have when $\epsilon \rightarrow 0$ :

$$
\begin{align*}
& -\inf _{g_{V_{\text {tot }}}(h) \in i n t}\left(\int_{0}^{1} \frac{\partial}{\partial t}\left\|h_{t}(.)\right\|^{2} d t\right) \leq \lim \inf 2 \epsilon^{2} \log P\left\{g_{V_{\text {tot }},, \epsilon}(.) \in O\right\}  \tag{2.9}\\
& \quad \lim \sup 2 \epsilon^{2} \log P\left\{g_{V_{t o t}, ., \epsilon}(.) \in O\right\} \leq-\inf _{g_{V_{\text {tot }}(h) \in c l o s} O}\left(\int_{0}^{1} \frac{\partial}{\partial t}\left\|h_{t}(.) d t\right\|^{2}\right) \tag{2.10}
\end{align*}
$$

In order to define $g_{V_{\text {tot }}, t}(z)(h)$, we replace formally in (2.6) $d_{t} B_{V_{\text {tot }}}^{i}(z)$ by $d_{t} h_{V_{\text {tot }}}^{i}(z)$.
By proceeding as in [37] we get:

Theorem II.1. If $k$ is big enough, the random field parametrized by $V_{t o t} z \rightarrow$ $g_{V_{t o t}, 1}(z)$ is $C^{r}$. Moreover the restriction to this random field to the connected components of the boundary of $V_{\text {tot }}$ are independents and have the same law.

Let us recall some geometrical background about the Wess-Zumino-NovikovWitten model ([16]). Let $V$ be an oriented surface with boundaries. Let $g$ be a $C^{r}$ map from $V$ into $G$ conveniently extended into a map $g_{t}(z)$ from $[0,1] \times V$ into $G$ such that $g_{0}(z)=e$. We define the Wess-Zumino term:

$$
\begin{equation*}
W_{V}(g)=-\frac{1}{6} \int_{[0,1] \times V}\left\langle g^{-1} d g \wedge\left[g^{-1} d g \wedge g^{-1} d g\right]\right\rangle \tag{2.11}
\end{equation*}
$$

where $\langle$,$\rangle is the canonical normalized Killing form on the Lie algebra of G$. We suppose that the 3 -form which is integrated in (2.11) represents an element of $H^{3}(G ; Z)$ (see [16] for this hypothesis). $\exp \left[2 \pi \sqrt{-1} W_{V}(g)\right]$ can be identified canonically to an element of $K_{\partial V, \partial g}$ where $K$ is an Hermitian line bundle over the set of $C^{r}$ maps from $\partial V$ into $G$. Let $\partial V_{i}$ be the oriented connected components of $\partial V$. We have a canonical inclusion map $\pi_{i}$ from $\partial V_{i}$ in $\partial V$. We deduce from it a map $\bar{\pi}_{i}$ from the set of maps from $\partial V$ in $G$ into the set of maps from $\partial V_{i}$ into $G$. Let $\Lambda_{i}$ be the hermitian bundle on the set of maps from $\partial V_{i}$ into $G$ constructed in [16]. $K=\otimes \bar{\pi}_{i}^{*} \Lambda_{i}$ endowed with its natural metric inherited from each $\Lambda_{i}$. We denote it $\otimes_{\text {exit }} \Lambda \otimes_{\text {in }} \Lambda$. Moreover, we can realize this expression as a map from the tensor products of Hermitian line bundle $\Lambda$ over the exit loop groups defined by restricting the field over each exit boundary to the tensor product of Hermitian line bundles $\Lambda$ over the input loop groups defined by restricting the field over each connected component of the input boundary. Therefore $\exp \left[2 \pi \sqrt{-1} W_{V}(g)\right]$ can be realized as an application from $\otimes_{\text {exit }} \Lambda$ into $\otimes_{\text {in }} \Lambda$ of modulus 1. This application is consistent with the operation of sewing surface.

Let $V_{\text {tot }}$ and the restriction of $g_{V_{t o t}, 1}($.$) to one connected component of the bound-$ ary of $V_{\text {tot }}$. Let $\Xi^{\prime}$ be the Hilbert space of section of $\Lambda$ over the $C^{r}$ loop group $L^{r}(G)$ endowed with the law arising from restricting the field to one boundary loops. Let $V_{i}$ be such a boundary loop. The laws of $g_{V_{\text {tot, }}}($.$) restricted to each V_{i}$ are the same. Let $\Psi_{i}\left(\left.g_{V_{t o t}, 1}()\right|_{.V_{i}}\right)$ a section of $\Lambda$ on the set of loops defined by $V_{i} .\left|\Psi_{i}\left(\left.g_{V_{t o t}, 1}()\right|_{.V_{i}}\right)\right|$ denotes a random variable which is $\left.g_{V_{t o t}, 1}()\right|_{.V_{i}}$ measurable, where $\left.g_{V_{t o t}, 1}()\right|_{.V_{i}}$ denotes the restriction to the random field to $V_{i}$. We put

$$
\begin{equation*}
\left\|\Psi_{i}\right\|_{\Xi_{i}^{\prime}}^{2}=E\left[\left|\Psi_{i}\left(\left.g_{V_{t o t}, 1}(.)\right|_{V_{i}}\right)\right|^{2}\right] . \tag{2.12}
\end{equation*}
$$

But the previous Hilbert norm don't depend of the chosen boundary loop $V_{i}$, and we get the definition of the Hilbert space $\Xi_{i}^{\prime}$. Let $L^{2}\left([0,1] \times V_{i}\right)$ be the Hilbert space of $L^{2}$ functionals with respect of $g_{V_{t o t,}}($.$) restricted to [0,1] \times V_{i}$. We put $\Xi_{i}=\Xi_{i}^{\prime} \otimes$ $L^{2}\left([0,1] \times V_{i}\right)$. We get always the same Hilbert space $\Xi$ independent of the choice of $V_{\text {tot }}$. If $g_{V_{t o t}, 1}(z)$ is the random map from $V_{\text {tot }}$ into $G$, we deduce the random map from $[0,1] \times V_{\text {tot }}$ into $G,(t, z) \rightarrow g_{V_{t o t}, 1}(z)$ with the the boudary condition $g_{V_{t o t}, 0}(z)=e$. We deduce from this the Wess-Zumino term $\exp \left[2 \pi \sqrt{-1} W_{V_{\text {tot }}}\left(g_{V_{t o t}, 1}\right)\right]$. Let us recall that the cinetic term in the W.Z.N.W. model is equal to $\exp [-I(g)]$ where $I(g)$ is the energy from the map $g$ from $V_{\text {tot }}$ into $G$. Compare with (2.9) and (2.10). In this work,
we will consider the same topological term and we will consider another cinetic term given by the law of $g_{V_{t o t}, 1}($.$) .$

Definition II.2. $H\left(V_{\text {tot }}, g_{V_{\text {tot }}}\right)$ is the operator from $\otimes_{\text {out }} \Xi$ into $\otimes_{\text {in }} \Xi$ where we put the tensor product along respectively the connected components of the exit boundary of $V_{\text {tot }}$ and of the input boundaries of $V_{\text {tot }}$ defined as follows: let $\Psi_{i}$ a section of $\Lambda$ at the $i^{\text {th }}$ connected component of the exit boundary:

$$
\begin{equation*}
H\left(V_{\text {tot }}, g_{V_{\text {oto }}}\right) \otimes_{\text {out }} \Psi_{i}=E\left[\exp \left[2 \pi \sqrt{-1} W_{V_{\text {tot }}}\left(g_{V_{\text {tot }}, 1}\right)\right] \otimes_{\text {out }} \Psi_{i} \mid B^{\prime}\left([0,1] \times \Sigma_{1}\right)\right] \tag{2.13}
\end{equation*}
$$

where $B^{\prime}\left([0,1] \times \Sigma_{1}\right)$ is the $\sigma$-algebra spanned by the random field $g_{V_{\text {tot }},(.)}$ restricted to the input data $[0,1] \times \Sigma_{1}$.

Let $\left(V_{t o t}^{1}, g_{V_{\text {tot }}}^{1}\right)$ and $\left(V_{\text {tot }}^{2}, g_{\text {tot }}^{2}\right)$ and ( $W_{\text {tot }}, g_{W_{\text {tot }}}$ ) got by sewing $V_{\text {tot }}^{1}$ along some exit boundaries coinciding with some input boundaries of $V_{\text {tot }}^{2}$. We call the sewing boundary $\tilde{\Sigma}$ in $W_{\text {tot }}$. We call $B([0,1] \times \tilde{\Sigma})$ the sigma algebra defined by (4.2) for the random field $(t, z) \rightarrow g_{W_{\text {tot }}, t}(z)$ parametrized by $[0,1] \times W_{\text {tot }}$. From Theorem IV.2, it satisfies (4.4). We deduce:

## Theorem II.3. We have:

$$
\begin{equation*}
H\left(W_{t o t}, g_{W_{t o t}}\right)=H\left(V_{t o t}^{1}, g_{V_{t o t}^{1}}\right) \circ H^{2}\left(V_{t o t}^{2}, g_{V_{t o t}^{2}}\right) \tag{2.14}
\end{equation*}
$$

where the composition goes for the Hilbert spaces which arises from the sewing boundaries.

Proof. Let $\Sigma_{s}$ be the sewing boundary in $W_{\text {tot }}$. We get almost surely:

$$
\begin{align*}
& \exp \left[2 \pi \sqrt{-1} W_{W_{t o t}}\left(g_{W_{t o t}, 1}\right)\right] \\
& =\exp \left[2 \pi \sqrt{-1} W_{V_{t o t}^{1}}\left(g_{V_{t o t}^{1}, 1}\right)\right] \circ \exp \left[2 \pi \sqrt{-1} W_{V_{t o t}^{2}}\left(g_{V_{t o t}^{2}, 1}\right)\right] . \tag{2.15}
\end{align*}
$$

By Markov property, the two term in the right hand side of (2.15) are conditionnally independent to $B^{\prime}\left([0,1] \times \Sigma_{s}\right)$. We have:

$$
\begin{aligned}
& H\left(W_{\text {tot }}, g_{W_{\text {to }}}\right) \otimes_{\text {out }} \Psi_{i} \\
(2.16) & =E\left[E\left[\exp \left[2 \pi \sqrt{-1} W_{W_{\text {ot }}}\left(g_{W_{\text {tot }}, 1}\right)\right] \otimes_{\text {out }} \Psi_{i} \mid B^{\prime}\left(\Sigma_{1} \cup \Sigma_{S}\right)\right] \mid B^{\prime}\left([0,1] \times \Sigma_{1}\right)\right] .
\end{aligned}
$$

But we have:

$$
\begin{align*}
& E\left[\exp \left[2 \pi \sqrt{-1} W_{W_{\text {tot }}}\left(g_{W_{\text {tot }}, 1}\right)\right] \mid B^{\prime}\left(\Sigma_{1} \cup \Sigma_{s}\right)\right]=E\left[\exp \left[2 \pi \sqrt{-1} W_{V_{\text {tot }}^{1}}\left(g_{V_{\text {tot }}^{1}, 1}\right)\right]\right. \\
& \quad \circ \exp \left[2 \pi \sqrt{-1} W_{V_{\text {tot }}^{2}}\left(g_{V_{\text {tot }}^{2}, 1}\right)\right] \otimes_{\text {out }} \Psi_{i} \mid B^{\prime}\left([0,1] \times\left(\Sigma_{1} \cup \Sigma_{s}\right)\right] . \tag{2.17}
\end{align*}
$$

By (4.4), where we choose as $O$ the interior of $V_{\text {tot }}^{1}$ in $W_{\text {tot }}$, the right hand-side in (2.17) is equal to

$$
\begin{align*}
E\left[\exp \left[2 \pi \sqrt{-1} W_{V_{\text {tot }}^{1}}\left(g_{V_{\text {tot }}^{1}, 1}\right)\right](E[ \right. & \exp \left[2 \pi \sqrt{-1} W_{V_{\text {tot }}^{2}}\left(g_{V_{\text {tot }}^{2}, 1}\right)\right] \\
& \left.\left.\left.\otimes_{\text {out }} \Psi_{i}\right] \mid B^{\prime}\left([0,1] \times \Sigma_{s}\right)\right] \mid B^{\prime}\left([0,1] \times \Sigma_{1}\right)\right] . \tag{2.18}
\end{align*}
$$

In (4.4), this decomposition formula is true for functionals, but we can come back to this case in (2.17) by introducing an orthonormal basis of $\Xi$.

If ( $V_{\text {tot }}, g_{V_{\text {tot }}}$ ) have only one connected component in the input boundary and $n$ connected component in the output boudary, we say that ( $V_{\text {tot }}, g_{V_{\text {tot }}}$ ) belongs to $E(n)$. An element of $E(n)$ realizes an element of $\operatorname{Hom}\left(\Xi^{\otimes n}, \Xi\right)$.

In particular, we will consider as $E(n)$ the case of $1+n$-punctured sphere $S_{\text {tot }}(1, n)$ with one input loop and $n$ output loops, by taking care of the history where we glue some subspheres in $S_{\text {tot }}(1, n) . E(n)$ is very similar to the space of trees with one root and $n$ exit vertices. Trees are an archetype of an operad: if $A(n)$ denotes the space of trees with $n$-exit vertices, we get an operation of $A(n) \times A\left(r_{1}\right) \times \cdots \times A\left(r_{n}\right)$ by grafting trees. This action is compatible with the action of symmetric group got by relabelling the exit vertices. $E(n)$ should correspond to the parameter set of a branching process on the loop space, time of branching being included: the branching mechanism is got when a loop splitts in two loops (and not by creating two loops as it is classical in branching process theory). $E(n)$ inherits an action of the symmetric group by labelling the connected components of the exit boudary. The action of sewing punctured spheres realizes a map from $E(n) \times E\left(r_{1}\right) \times \cdots \times E\left(r_{n}\right)$ into $E\left(\sum r_{i}\right)$ which is compatible with the action of the symmetric group. We say that $E(n)$ is an operad. On the other hand, $\operatorname{Hom}\left(\Xi^{n}, \Xi\right)$ realizes clearly an operad, by composition of the homomorphisms. We get from Theorem II.3:

Theorem II.4. If $\left(W_{\text {tot }}, g_{W_{\text {tot }}}\right)$ belongs to $E(n), H\left(W_{\text {tot }}, g_{W_{\text {tot }}}\right)$ realizes a map from the operad $E(n)$ into the operad $\operatorname{Hom}\left(\Xi^{\otimes n}, \Xi\right)$.

If we consider the case of the punctured sphere, this corresponds to a kind of Branching process on the loop space.

## III. Stochastic Chern-Simons theory

We consider now as $\left(V, g_{V}\right)$ the case of an oriented 3-dimensional manifold $V$ with boundaries having connected components some oriented Riemannian surfaces $\left(\Sigma_{i}, g_{\Sigma_{i}}\right)$. The input boundaries are called $\Sigma_{i}^{i n}$ and the output boundaries are called $\Sigma_{i}^{\text {out }}$. This means that $V$ realizes a bordism from $\bigcup \Sigma_{i}^{\text {in }}$ into $\bigcup \frac{\Sigma_{i}^{\text {out }}}{V}$. We can find a 3-dimensional manifold whose boundary is $\Sigma_{i}$. Let us consider $\bar{V}$ got from $V$ by sewing these 3-dimensional manifolds to each $\Sigma_{i} . \bar{V}$ has a Riemannian metric inher-
ited from $\Sigma_{i}$. Let $\Delta_{\bar{V}}$ be the Hodge Laplacian operating on 1-forms on $\bar{V}$ with values in the Lie algebra of a compact simply connected Lie group $G$, endowed with the natural Killing metric. We introduce the Sobolev space $H_{\bar{V}}$ of 1-form $\omega$ with values in $\operatorname{Lie}(G)$ such that:

$$
\begin{equation*}
\int_{\bar{V}}\left\langle\left(\Delta_{\bar{V}}^{k}+1\right) \omega,\left(\Delta_{\bar{V}}^{k}+1\right) \omega\right\rangle d m_{\bar{V}}<\infty \tag{3.1}
\end{equation*}
$$

We denote by $\omega_{\bar{V}}$ the centered Gaussian measure in $H_{\bar{V}}$. If $k$ is big enough, $\omega_{\bar{V}}(z)$ is almost surely a 1-form which is $C^{r}$.

Let $\bar{\Sigma}$ got from $[0,1] \times \Sigma$ by sewing these 3 -dimensional manifolds along the boundary. $\bar{\Sigma}$ inherites a canonical metric from the metric on $\Sigma$. Let $\Delta_{\bar{\Sigma}}$ be the Laplacian operating on 1-form on $\bar{\Sigma}$ with values in $\operatorname{Lie}(G)$. Let $H_{\bar{\Sigma}}$ be the Hilbert Sobolev space of 1-forms $\omega$ on $\bar{\Sigma}$ with values in $\operatorname{Lie}(G)$ such that:

$$
\begin{equation*}
\int_{\bar{\Sigma}}\left\langle\left(\Delta_{\bar{\Sigma}}^{k}+1\right) \omega,\left(\Delta_{\bar{\Sigma}}^{k}+1\right) \omega\right\rangle d m_{\bar{\Sigma}}<\infty \tag{3.2}
\end{equation*}
$$

We consider the centered Gaussian measure on $H_{\bar{\Sigma}}$. This gives a random 1-form $\omega_{\tilde{\Sigma}}$ which is $C^{r}$ if $k$ is big enough.

Let $g_{V}(z)$ be a map from $V$ into $[0,1]$ equal to 1 on $V$ where we have removed the output collars $\left[0,1 / 2\left[\times \Sigma_{i}^{\text {out }}\right.\right.$ and where we have removed the input collars $] 1 / 2 ; 1] \times \Sigma_{i}^{i n}$. We suppose that $g_{V}$ is equal to zero on a neighborhood of the boudaries of $V$.

Let $g^{\text {out }}$ be a smooth map from $[0,1 / 2]$ into $[0,1]$ equal to 0 only in 0 and equal to 1 in a neighborhood of $1 / 2$. Let $g^{i n}$ be a smooth map from $[1 / 2,1]$ equal to 0 only in 1 and equal to 1 in a neighborhood of $1 / 2$.

Let $V$ be constructed as above. We consider the Gaussian random field:

$$
\begin{equation*}
\omega_{V}=g_{V} \omega_{\bar{V}}+\sum_{\text {in }} g^{\text {in }} \omega_{\bar{\Sigma}_{i}^{\text {in }}}+\sum_{\text {out }} g^{\text {out }} \omega_{\bar{\Sigma}_{i}^{\text {out }}} \tag{3.3}
\end{equation*}
$$

where we take independent $\omega_{\bar{V}}, \omega_{\bar{\Sigma}_{i}^{i n}}$ and $\omega_{\bar{\Sigma}_{i}^{o u t}} . \omega_{V}$ is a random $C^{r}$ 1-form on $V$ with values in $\operatorname{Lie}(G)$.

Let us consider the trivial bundle $V \times G$ on $V$. By this trivialization, $\omega_{V}$ realizes a random $C^{r}$ connection on this bundle.

An object $V_{\text {tot, } k}=\left(V_{1} \cup V_{2} . . \cup V_{k}\right)$ is constructed inductively as follows: $V_{1}$ is a 3-dimensional oriented Riemannian manifold constructed as before. $V_{\text {tot }, k+1}$ is constructed from $V_{\text {tot }, k}$ where we sew some exit boudaries of $V_{\text {tot }, k}$ along some input boundaries of $V_{k+1}$.

We can construct inductively $\omega_{V_{\text {tot,k+1}}}$ as follows: if $k=1$, it is $\omega_{V} . \omega_{V_{k+1}}$ is constructed from Gaussian fields independent of those which have constructed $\omega_{V_{\text {ot }, k},}$, except for the Gaussian fields in the input boudaries of $\omega_{V_{\text {ot, } k}}$ which coincide with the Gaussian fields in the output boudaries of $V_{\text {tot }, k}$ which are sewed to the corresponding
input boudaries of $V_{k+1}$.

Theorem III.1. If $k$ is big enough, $\omega_{V_{\text {too }}}$ is almost surely $C^{r}$.
Let us recall some background about the Chern-Simons functional (see [16]). If $\Sigma_{i}$ is connected, we can construct an Hermitian line bundle $\Lambda\left(\Sigma_{i}\right)$ over the set of $C^{r}$ connection over $\Sigma_{i}$ of the trivial bundle $\Sigma_{i} \times G$ on $\Sigma_{i}$. Let us do the following hypothesis: let $\sigma$ be the invariant 3-form on $G$ which is equal to $\sigma(X, Y, Z)=\langle X,[Y, Z]\rangle$ at the level of the Lie algebra. Let us suppose that $1 / 6 \sigma$ represents an element of $H^{3}(G ; Z)$.

Under this hypothesis, it is possible to define as it was used for instance in [16] the Chern-Simons functional $\exp \left[2 \pi \sqrt{-1} C_{C . S}\left(\omega_{V}\right)\right]$ where $\omega_{V}$ is a connection on $V$ as a linear application of modulus one from $\otimes_{\text {out }} \Lambda\left(\Sigma_{i}^{\text {out }}\right)\left(\omega_{\Sigma_{i}^{\text {out }}}\right)$ into $\otimes_{\text {in }} \Lambda\left(\Sigma_{i}^{\text {in }}\right)\left(\omega_{\Sigma_{i}^{\text {in }}}\right)$ where we restrict the connection $\left(\omega_{V}\right)$ to the input and output boundaries $\Sigma_{i}$ of $V$. We call $\omega_{\Sigma_{i}}$ these restrictions. These operations are consistent with the operation of sewing 3 -dimensional manifolds.

Let us recall, if $V$ has no boundary, that the Chern-Simons action is equal to

$$
\begin{equation*}
\frac{k}{2 \pi} \int_{V} \operatorname{Tr}\left[\omega_{V} \wedge d \omega_{V}+\frac{2}{3} \omega_{V} \wedge \omega_{V} \wedge \omega_{V}\right] \tag{3.4}
\end{equation*}
$$

wherec $\operatorname{Tr}$ is got by imbedding the Lie group $G$ into $S O(n)$ for some big convenient $n$.

Let $H\left(\Sigma, g_{\Sigma}\right)$ the Hilbert space of sections of $\Lambda(\Sigma)$ for the measure got by restricting $\omega_{\bar{\Sigma}}$ to $\Sigma$.

Definition III.2. $H\left(V_{\text {tot }}, g_{V_{\text {ot }}}\right)$ is the operator from $\otimes_{\text {out }} H\left(\Sigma_{i}^{\text {out }}, g_{\Sigma_{i}^{\text {out }}}\right)$ into the Hilbert space $\otimes_{i n} H\left(\Sigma_{i}^{i n}, g_{i=}^{\text {in }^{n}}\right)$ defined as follows: let $\Psi_{i}^{\text {out }}$ belonging to $H\left(\Sigma_{i}^{\text {out }}, g_{\Sigma_{i}^{\text {out }}}\right)$ :

$$
\begin{equation*}
H\left(V_{\text {tot }}, g_{V_{\text {tot }}}\right) \otimes_{\text {out }} \Psi_{I}^{\text {out }}=E\left[\exp \left[2 \pi \sqrt{-1} S_{C S}\left(\omega_{V_{\text {tot }}}\right)\right] \otimes \Psi_{i}^{\text {out }}\left(\omega_{\Sigma_{i}^{\text {out }}}\right) \mid B^{\prime}\left(\bigcup \Sigma_{i}^{\text {in }}\right)\right] \tag{3.5}
\end{equation*}
$$

where $B^{\prime}\left(\bigcup \Sigma_{i}^{i n}\right)$ is the $\sigma$-algebra spanned by the restriction $\omega_{V}$ to the union of input boudaries $\Sigma_{i}^{i n}$.

Let $\left(V_{t o t}^{1}, g_{V_{t o t}^{1}}\right)$ and $\left(V_{t o t}^{2}, g_{V_{t o t}^{2}}\right)$ and $\left(W_{\text {tot }}, g_{W_{\text {tot }}}\right)$ got by sewing $V_{\text {tot }}^{1}$ and $V_{\text {tot }}^{2}$ along some exit boundaries from $V_{t o t}^{1}$ and some input boundaries of $V_{\text {tot }}^{2}$. Since the stochastic Chern-Simons functional $\exp \left[2 \pi \sqrt{-1} S_{C . S}\left(\omega_{V_{t o t}^{i}}\right)\right]$ is measurable for the $\sigma$-algebra spanned by the fields $\omega_{V V_{i o t}^{i}}$, we deduce from Theorem IV.2:

Theorem III.3. We have:

$$
\begin{equation*}
H\left(W_{t o t}, g_{W_{t o t}}\right)=H\left(V_{t o t}^{1}, g_{V_{t o t}^{1}}\right) \circ H^{2}\left(V_{t o t}^{2}, g_{V_{t o t}^{2}}\right) \tag{3.6}
\end{equation*}
$$

where the composition goes from the Hilbert spaces which arise from the sewing boundary.

If ( $V_{\text {tot }}, g_{V_{\text {tot }}}$ ) has only one connected component in the input boundary ( $\Sigma, g_{\Sigma}$ ) and $n$-connected component in the output boundary constituted of the same $\left(\Sigma, g_{\Sigma}\right)$, we say that we have an element of $E_{n}\left(\Sigma, g_{\Sigma}\right)$. The collection of $E_{n}\left(\Sigma, g_{\Sigma}\right)$ constitutes an operad when ( $\Sigma, g_{\Sigma}$ ) is fixed. We put $\Xi=H\left(\Sigma, g_{\Sigma}\right)$. An element of $E_{n}\left(\Sigma, g_{\Sigma}\right)$ realizes an element of $\operatorname{Hom}\left(\boldsymbol{\Xi}^{\otimes n}, \boldsymbol{\Xi}\right)$.

Theorem III.4. If $\left(W_{t o t}, g_{W_{\text {tot }}}\right)$ belongs to $E_{n}\left(\Sigma, g_{\Sigma}\right), H\left(W_{t o t}, g_{W_{\text {tot }}}\right)$ realizes a map from the operad $E_{n}\left(\Sigma, g_{\Sigma}\right)$ into the operad $\operatorname{Hom}\left(\Xi^{\otimes n}, \Xi\right)$.

## IV. Appendix

This appendix constitutes a brief review concerning the Markov property for Gaussian random fields. We refer to [29] and references therein for more details.
$(\Omega, F, P)$ be a probability space, and $X(z)$ a Gaussian continuous centered random field with parameter space a finite manifold $T$ endowed with a Riemannian distance $d$.

If $O$ is an open subset of $T$, we define

$$
\begin{equation*}
B(O)=\sigma(X(z) ; z \in O) \tag{4.1}
\end{equation*}
$$

anf for an closed subset $D$, we define

$$
\begin{equation*}
B(D)=\bigcap_{\epsilon>0} B\left(D_{\epsilon}\right) \tag{4.2}
\end{equation*}
$$

where $D_{\epsilon}=\left\{z \in T: \inf _{z^{\prime} \in D} d\left(z, z^{\prime}\right)<\epsilon\right\}$.
Definition IV.1. A random field has the Markov property with respect to an open set $O$ if for any $B(\bar{O})$-measurable functional $\psi$ :

$$
\begin{equation*}
E\left[\psi \mid B\left(O^{c}\right)\right]=E[\psi \mid B(\partial O)] . \tag{4.3}
\end{equation*}
$$

A random field is $G$-markov if it has the Markov property with respect to all open sets $O$.

Markov property with respect to $O$ is equivalent to the following statement: for any event $A_{1} B(\bar{O})$-measurable and for any event $A_{2} B\left(O^{c}\right)$-measurable:

$$
\begin{equation*}
P\left(A_{1} \cap A_{2} \mid B(\partial O)\right]=P\left(A_{1} \mid B(\partial O)\right] P\left[A_{2} \mid B(\partial O)\right] . \tag{4.4}
\end{equation*}
$$

Let us recall that the reproducing Hilbert space $H$ of the continuous Gaussian random field is given as follows: if $X$ is a linear random variable of the Gaussian random
field, we put:

$$
\begin{equation*}
f_{X}(z)=E[X X(z)] \tag{4.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\langle f_{X}, f_{Y}\right\rangle=E[X Y] . \tag{4.6}
\end{equation*}
$$

If $e_{z}\left(z^{\prime}\right)$ is the covariance of the Gaussian random field,

$$
\begin{equation*}
E\left[X(z) X\left(z^{\prime}\right)\right]=e_{z}\left(z^{\prime}\right) \tag{4.7}
\end{equation*}
$$

we have

$$
\begin{equation*}
f(z)=\left\langle f, e_{z}(.)\right\rangle \tag{4.8}
\end{equation*}
$$

Let us recall ([29] Theorem 5.1):

Theorem IV.2. A random continuous Gaussian field $X$ with reproducing Hilbert space $H$ is a Markov field if and only if the two following conditions are checked:
i) For all $f_{1}, f_{2} \in H$ with support disjoint, $\left\langle f_{1}, f_{2}\right\rangle=0$.
ii) if $f \in H$ is such that $f=f_{1}+f_{2}$ with disjoint supports, then $f_{1}$ and $f_{2}$ belong to $H$.

We have a natural generalization of Theorem IV. 2 to the case where the random field takes its values in $R^{d}$.
