# Quadratic Twists of Elliptic Curves Associated to the Simplest Cubic Fields 

By Dongho Byeon<br>Department of Mathematics, Pohang University of Science and Technology, Korea<br>(Communicated by Shokichi IYANAGA, M. J. A., Dec. 12, 1997)

1. Introduction. Let $m$ be a rational integer such that $m^{2}+3 m+9$ is square-free. Let $K$ be the cubic field defined by the irreducible polynomial over the rational number field $\boldsymbol{Q}$

$$
f(x)=x^{3}+m x^{2}-(m+3) x+1
$$

We call $K$ a simplest cubic field.
In [2], Washington has studied the elliptic curve $E$ defined over $\boldsymbol{Q}$ by

$$
E: y^{2}=x^{3}+m x^{2}-(m+3) x+1
$$

and has shown that the 2 -rank of ideal class group of $K$ is greater than the rank of the group of rational points of $E$.

In this paper, we consider quadratic twists of the elliptic curve $E$ and applying Washington's idea to our twists, show that the 2 -rank of ideal class group of $K$ is also greater than the ranks of the groups of rational points of some infinitely many quadratic twists of the elliptic curve $E$.
2. Main theorem. Let $a(\neq 0)$ be a rational integer and $E_{a}$ be the quadratic twist of $E$ defined by

$$
E_{a}: a y^{2}=x^{3}+m x^{2}-(m+3) x+1
$$

Multiply each side of $E_{a}$ by $a^{3}$ and replace $a^{2} y$, $a x$ by $y, x$ respectively. Then we have

$$
E_{a}: y^{2}=x^{3}+m a x^{2}-(m+3) a^{2} x+a^{3}
$$

The discriminant of $E_{a}$ is $16 a^{6}\left(m^{2}+3 m+9\right)$ and the $J$-invariant of $E_{a}$ is $256\left(m^{2}+3 m+9\right)$.

$$
\text { Let } f_{a}(x)=x^{3}+m a x^{2}-(m+3) a^{2} x+a^{3}
$$

Then the cubic field defined by the irreducible polynomial $f_{a}(x)$ is also $K$ because

$$
f_{a}(x)=(x-a \rho)\left(x-a \rho^{\prime}\right)\left(x-a \rho^{\prime \prime}\right)
$$

where $\rho$ is the negative root of $f(x)$ and $\rho^{\prime}=1 /$ ( $1-\rho$ ) and $\rho^{\prime \prime}=1-1 / \rho$ are the other two roots of $f(x)$. Thus the 2 -torsion points on $E_{a}$ are the points $(a \rho, 0),\left(a \rho^{\prime}, 0\right),\left(a \rho^{\prime \prime}, 0\right)$, none of which is rational.

For each rational prime $p \leq \infty$, let $\boldsymbol{Q}_{p}$ de-

[^0]note the completion of $\boldsymbol{Q}$ at $p$ and $E_{a}\left(\boldsymbol{Q}_{p}\right)$ be the group of $\boldsymbol{Q}_{\boldsymbol{p}}$-points of $\boldsymbol{E}_{a}$. If $\boldsymbol{p}$ does not split in the cubic field $K$, let $K_{p}$ denote the completion of $K$ at the prime above $p$ and define the homomorphism
$$
\lambda_{p}: E_{a}\left(\boldsymbol{Q}_{p}\right) \rightarrow K_{p}^{\times} /\left(K_{p}^{\times}\right)^{2},(x, y) \rightarrow x-a \rho
$$

If $p$ splits, let

$$
\begin{aligned}
& \lambda_{p}: E_{a}\left(\boldsymbol{Q}_{p}\right) \rightarrow\left(\left(\boldsymbol{Q}_{p}^{\times} /\left(\boldsymbol{Q}_{p}^{\times}\right)^{2}\right)^{3}\right. \\
& (x, y) \rightarrow\left(x-a \rho, x-a \rho^{\prime}, x-a \rho^{\prime \prime}\right) \\
& \quad x \neq a \rho, a \rho^{\prime}, a \rho^{\prime \prime} \\
& (a \rho, 0) \rightarrow\left(z, a\left(\rho-\rho^{\prime}\right), a\left(\rho-\rho^{\prime \prime}\right)\right)
\end{aligned}
$$

where $z$ is chosen so that $z a^{2}\left(\rho-\rho^{\prime}\right)\left(\rho-\rho^{\prime \prime}\right) \in$ $\left(K^{\times}\right)^{2}$. One defines $\lambda_{p}\left(a \rho^{\prime}, 0\right)$ and $\lambda_{p}\left(a \rho^{\prime \prime}, 0\right)$ similarly. Let $S_{2}\left(E_{a}\right)$, the Selmer group, be the subgroup of elements of $K^{\times} /\left(K^{\times}\right)^{2}$ which are in the image of $\lambda_{p}$ for all $p$. The Tate-Shafarevich group $Ш_{2}\left(E_{a}\right)$ is defined by the exactness of the sequence

$$
0 \rightarrow E_{a}(\boldsymbol{Q}) / 2 E_{a}(\boldsymbol{Q}) \rightarrow S_{2}\left(E_{a}\right) \rightarrow Ш_{2}\left(E_{a}\right) \rightarrow 0
$$

Then we have the following theorem:
Theorem. Let $a(\neq 0)$ be a rational integer and assume that a has no prime divisor which splits in $K$. Let $E_{a}(\boldsymbol{Q})$ be the group of rational points of $E_{a}$ and rank $E_{a}(\boldsymbol{Q})$ denote the rank of $E_{a}(\boldsymbol{Q})$ over Z. Let $C_{2}(K)$ be the 2-part of ideal class group of $K$, and $r k_{2}\left(C_{2}(K)\right)$ denote the 2 -rank (i.e, the dimension as a $\boldsymbol{Z} / 2 \boldsymbol{Z}$-vector space) of $C_{2}(K)$. Then we have

$$
\operatorname{rank} E_{a}(\boldsymbol{Q}) \leq r k_{2}\left(C_{2}(K)\right)+1
$$

Proof. First we define the map $S_{2}\left(E_{a}\right) \rightarrow$ $C_{2}(K)$. Let $\alpha \in K^{\times}$represent an element of $S_{2}\left(E_{a}\right)$, so $\alpha \in \operatorname{Im} \lambda_{p}$ for all $p$. If $p$ does not split in $K$, then $\alpha=(x-a \rho) \beta^{2}$ for some $\beta \in K_{p}^{\times}$ and $(x, y) \in E_{a}\left(\boldsymbol{Q}_{p}\right)$. Let $\nu$ be the valuation at the prime above $p$ in $K_{p}$. Then since $\nu(x-a \rho)$ $=\nu\left(x-a \rho^{\prime}\right)=\nu\left(x-a \rho^{\prime \prime}\right)$ and $\nu(x-a \rho)$ $\nu\left(x-a \rho^{\prime}\right) \nu\left(x-a \rho^{\prime \prime}\right)=\nu\left(y^{2}\right), \nu(\alpha)$ is even. Now suppose $p$ splits in $K$. Let $\alpha^{\prime}, \alpha^{\prime \prime}$ denote the conjugates of $\alpha$ over $\boldsymbol{Q}$. Then we have
$\left(\alpha, \alpha^{\prime}, \alpha^{\prime \prime}\right)=\left((x-a \rho) \beta_{1}^{2},\left(x-a \rho^{\prime}\right) \beta_{2}^{2},\left(x-a \rho^{\prime \prime}\right) \beta_{3}^{2}\right)$ for some $\beta_{i} \in \boldsymbol{Q}_{p}$ and $(x, y) \in E_{a}\left(\boldsymbol{Q}_{p}\right)$. Let $\nu$ be
the $p$-adic valuation in $\boldsymbol{Q}_{p}$. If $\nu(x-a \rho)$ and $\nu\left(x-a \rho^{\prime}\right)$ or $\nu\left(x-a \rho^{\prime \prime}\right)$ are positive, then so is $\nu\left(a\left(\rho-\rho^{\prime}\right)\right)$ or $\nu\left(a\left(\rho-\rho^{\prime \prime}\right)\right)$, hence $p$ divides $a^{3}\left(m^{2}+3 m+9\right)$. Since $a$ has no prime divisor which splits in $K, p$ can not divide $a$. So $p$ should divide $\left(m^{2}+3 m+9\right)$. But since $m^{2}+$ $3 m+9$ is assumed to be square-free, $p$ should ramify in $K$ by [2. Proposition 1]. Thus we have a contradiction. If only $\nu(x-a \rho)$ is positive, it must be even. If $\nu(x-a \rho)$ is negative, then $\nu(x$ $-a \rho)=\nu\left(x-a \rho^{\prime}\right)=\nu\left(x-a \rho^{\prime \prime}\right)$ and they are even. Therefore, $\alpha$ must have even valuation at all primes in $K$, so the ideal $(\alpha)$ is the square of an ideal of $K:(\alpha)=I^{2}$. So we can define the $\operatorname{map} S_{2}\left(E_{a}\right) \rightarrow C_{2}(K)$ by $\alpha \rightarrow I$.

Now we consider the kernel of the map. We compute it in detail only for the case that $a$ is negative because it can be computed similarly for the case that $a$ is positive. If $I$ is principal, then $\alpha=\epsilon \beta^{2}$ for some $\beta \in K^{\times}$and some unit $\epsilon$. Since $x-a \rho<x-a \rho^{\prime}<x-a \rho^{\prime \prime}$ and the product is $y^{2} \geq 0$, the signs of $\alpha, \alpha^{\prime}, \alpha^{\prime \prime}$ should be,++ , + or,--+ . Therefore, for signs of $\epsilon, \epsilon^{\prime}, \epsilon^{\prime \prime}$, there are the two possibilities. Since $\rho, \rho^{\prime}, \rho^{\prime \prime}$ have signs,,-++ , we find that either $\epsilon$ or - $\rho^{\prime} \epsilon$ is totally positive, hence square by [2]. Therefore, if $I$ is principal, either $\alpha$ or $-\rho^{\prime} \alpha$ is a square, so the kernel of the map is contained in $\left\{1,-\rho^{\prime}\right\}\left(K^{\times}\right)^{2} /\left(K^{\times}\right)^{2}$. Similarly, for the case that $a$ is positive, the kernel of the map is contained in $\{1,-\rho\}\left(K^{\times}\right)^{2} /\left(K^{\times}\right)^{2}$.

Surjectivity of the map is also derived from the slight modification of Washington's argument in the proof of [2. Theorem 1]. Thus we have

$$
r k_{2}\left(S_{2}\left(E_{a}\right)\right)=r k_{2}\left(C_{2}(K)\right)+1 \text { or } r k_{2}\left(C_{2}(K)\right)
$$

and from the exact sequence

$$
0 \rightarrow E_{a}(\boldsymbol{Q}) / 2 E_{a}(\boldsymbol{Q}) \rightarrow S_{2}\left(E_{a}\right) \rightarrow Ш_{2}\left(E_{a}\right) \rightarrow 0
$$

we have

$$
\operatorname{rank} E_{a}(\boldsymbol{Q}) \leq r k_{2}\left(S_{2}\left(E_{a}\right)\right)
$$

Finally we have

$$
\operatorname{rank} E_{a}(\boldsymbol{Q}) \leq r k_{2}\left(C_{2}(K)\right)+1
$$

Thus we have proved the theorem completely.
Remark 1. The assumption that the rational integer $a$ has no prime divisor which splits in
$K$ is essential for our proof. For example, let $q$ be a rational prime which splits in $K$ and $\alpha \in K^{\times}$ represent an element of $S_{2}\left(E_{q}\right)$. In this case, $\alpha$ need not have even valuation at all prime divisors in $K$ above $q$. Let $\alpha^{\prime}, \alpha^{\prime \prime}$ denote the conjugates of $\alpha$ over $\boldsymbol{Q}$. Then we have $\left(\alpha, \alpha^{\prime}, \alpha^{\prime \prime}\right)=\left((x-q \rho) \beta_{1}^{2},\left(x-q \rho^{\prime}\right) \beta_{2}^{2},\left(x-q \rho^{\prime \prime}\right) \beta_{3}^{2}\right)$ for some $\beta_{i} \in \boldsymbol{Q}_{q}$ and $(x, y) \in E_{q}(\boldsymbol{Q})$. Let $\nu$ be the $q$-adic valuation of $\boldsymbol{Q}_{q}$. If one of $\nu(x-q \rho)$, $\nu\left(x-q \rho^{\prime}\right), \nu\left(x-q \rho^{\prime \prime}\right)$ is positive, then so are all of them and $\nu(x)>0$. If $\nu(x) \geq 2$ then $\nu(x$ $-q \rho)=\nu\left(x-q \rho^{\prime}\right)=\nu\left(x-q \rho^{\prime \prime}\right)=1$. But $\nu(x-q \rho) \nu\left(x-q \rho^{\prime}\right) \nu\left(x-q \rho^{\prime \prime}\right)=\nu\left(y^{2}\right)$ is even. So we have a contradiction. Thus $\nu(x)=$ 1 and let $x=q b$, where $b \in \boldsymbol{Q}_{q}$ and $\nu(b)=0$. If two of $\nu(b-\rho), \nu\left(b-\rho^{\prime}\right), \nu\left(b-\rho^{\prime \prime}\right)$ are positive, then so is $\nu\left(\rho-\rho^{\prime}\right), \nu\left(\rho-\rho^{\prime \prime}\right)$ or $\nu\left(\rho^{\prime}\right.$, $\left.-\rho^{\prime \prime}\right)$, hence $q$ divides $\left(m^{2}+3 m+9\right)$. Since $m^{2}$ $+3 m+9$ is assumed to be square-free, $q$ should ramify in $K$ by [2. Proposition 1]. So we also have a contradiction. Thus only one of $\nu(b$ $-\rho), \nu\left(b-\rho^{\prime}\right), \nu\left(b-\rho^{\prime \prime}\right)$ is positive and it must be odd. Therefore only one of $\nu(x-q \rho)$, $\nu\left(x-q \rho^{\prime}\right), \nu\left(x-q \rho^{\prime \prime}\right)$ is even and the others are one. This means that for some prime divisor in $K$ above $q, \alpha$ has odd valuation. Thus we cannot define the map $S_{2}\left(E_{q}\right) \rightarrow C_{2}(K)$.

Remark 2. In [1], Kawachi and Nakano have obtained an extension of Washington's result in [2] to some other kinds of cubic polynomials and using the twist $E_{-1}$ in the notation in this paper, have improved the result of Washington.

Aknowledgement. The author would like to thank the refree for many valuable remarks.
