# 158. On Fields of Division Points of Algebraic Function Fields of One Variable 

By Makoto IsHidA<br>Department of Mathematics, Tsuda College, Tokyo<br>(Comm. by Zyoiti Suetuna, m.J.A., Dec. 12, 1963)

Let $K$ be a field of algebraic functions of one variable over an algebraically closed constant field $k$. Let $D_{0}(K)$ be the group of all the divisors of degree 0 of $K$ and $C(K)$ the divisor class group of $K$, i.e. the factor group of $D_{0}(K)$ by the subgroup consisting of all the divisors which are linearly equivalent to 0 (in notation: $\sim 0$ ). We use the additive notation for the group laws of $D_{0}(K)$ and $C(K)$. Let $g$ be the genus of $K$. Then, for a natural number $n$ prime to the characteristic of $k$, it is known that there exist exactly $n^{2 g}$ elements $c_{1}, \cdots, c_{N}\left(N=n^{2 g}\right)$ of $C(K)$ such that $n c_{i}=0$. We call these $c_{i}$ the n-division points of $C(K)$.

Let $D_{1}, \cdots, D_{N}$ be an arbitrary system of representative divisors of the classes $c_{1}, \cdots, c_{N}$ ( $c_{i}$ is the divisor class containing $D_{i}$ ). Then $n D_{i}$ is linearly equivalent to 0 and so there exist $N$ elements $x_{1}, \cdots, x_{N}$ of $K$ such that the divisor $\left(x_{i}\right)$ of $x_{i}$ is equal to $n D_{i}$. We consider the subfield $K_{n}=k\left(x_{1}, \cdots, x_{N}\right)$ of $K$ generated by $x_{1}, \cdots, x_{N}$ over $k$. We shall call such a field $K_{n}$ a field of $n$-division points of $K$. Since there are infinitely many choices of systems of representative divisors of the classes $c_{i}$, there are also, for a fixed given $n$, infinitely many fields of $n$-division points of $K$. We note that if $n>1, K_{n}$ has the transcendental degree 1 over $k$ and so the degree $\left[K: K_{n}\right.$ ] is finite. In fact, for $n>1$, some $c_{i}$ is not equal to 0 and so $x_{i}$ is not a constant.

Now we shall prove the following
Theorem. Suppose $g \geqq 2$. Let $l \geqq 3$ be a prime number different from the characteristic of $k$. Then, for any field $K_{l}$ of $l$-division points of $K, K$ is purely inseparable over $K_{l}$. In particular, if the characteristic of $k$ is 0 , we have $K=K_{l}$.

The case where $l=2$ (and the characteristic $=0$ ) was considered by Arima in [1]. We shall prove our theorem in the separable case by the same idea.

The proof of the theorem is divided into two cases.

1) First we consider the case where $K$ is separable over $K_{l}$. We assume that $K \neq K_{l}$ and deduce a contradiction. Let $g_{0}$ be the genus of $K_{l}$. Then, as $g \geqq 2$ and $K \neq K_{l}$, we have $g>g_{0}$ by the formula of Hurwitz. We denote by $\left(x_{i}\right)_{K}$ and $\left(x_{i}\right)_{x_{l}}$ the divisors of the function
$x_{i}$ in $K$ and $K_{l}$ respectively. We also denote by $f^{-1}$ the conorm mapping of divisors for the extension $K / K_{l}$ (cf. Chevalley [2]). If $\left(x_{i}\right)_{k_{l}}=l e_{i}$ and $\left(x_{j}\right)_{K_{l}}=l e_{j}$ with divisors $e_{i}$ and $e_{j}$ of $K_{l}$, then, as in [1], $e_{i}$ and $e_{j}(i \neq j)$ determines distinct $l$-division points of $C\left(K_{l}\right)$. In order to prove this statement, we use the fact that $f^{-1}$ is a homomorphism and $f^{-1}\left(\left(x_{i}\right)_{K_{l}}\right)=\left(x_{i}\right)_{K}$. Hence at most $l^{2 g_{0}}$ divisors $\left(x_{i}\right)_{K_{l}}$ are of the form $l e_{i}$ and so there exist at least $l^{2 g}-l^{2 g_{0}}(>0)$ functions $x_{j}$ such that the divisors $\left(x_{j}\right)_{K_{l}}$ have the form

$$
(*) \quad\left(x_{j}\right)_{K_{l}}=\cdots+t p+\cdots, \quad t \neq 0(\bmod l),
$$

where $p$ is a prime divisor of $K_{l}$ and the right hand side is the reduced expression. Such $x_{j}$ and $\left(x_{j}\right)_{k_{l}}$ will be called an element and a divisor of (*)-type. Let $M=\left\{p_{1}, \cdots, p_{m}\right\}$ be the set of all the prime divisors $p_{i}$ of $K$ which appear in the reduced expression of some $\left(x_{j}\right)_{K_{l}}$ of (*)-type with the coefficient $\equiv 0(\bmod l)$. We write all the divisors $\left(x_{j}\right)_{K_{l}}$ of (*)-type as follows:

$$
\left(x_{j}\right)_{K_{l}}=a_{j}+l b_{j},
$$

where $a_{j}$ is of the form $t_{j 1} p_{1}+\cdots+t_{j m} p_{m}$ with $0 \leqq t_{j i} \leqq l-1$ and $\left(t_{j 1}, \cdots, t_{j m}\right) \neq(0, \cdots, 0)$. If we have $a_{j}=a_{h}(j \neq h)$, then we have $l f^{-1}$ $\left(b_{j}-b_{h}\right)=f^{-1}\left(\left(x_{j}\right)_{K_{l}}-\left(x_{h}\right)_{K_{l}}\right)=\left(x_{j}\right)_{K}-\left(x_{h}\right)_{K}=l D_{j}-l D_{h}$ and so $f^{-1}\left(b_{j}-b_{h}\right)$ $=D_{i}-D_{h}$. So we have $b_{j}-b_{h}+0$ (not linearly equivalent to 0 ) but $l\left(b_{j}-b_{h}\right)=\left(x_{j}\right)_{K_{l}}-\left(x_{h}\right)_{K_{l}} \sim 0$. Hence we see that, for a given $a_{j}$, the number of $\left(x_{h}\right)_{K_{l}}$ with $a_{h}=a_{j}$ is at most equal to the number of the $l$-division points of $C\left(K_{l}\right)$ i.e. $l^{290}$. On the other hand, the number of such $a_{j}$ is at most equal to $l^{m-1}-1$. In fact, since $\operatorname{deg}\left(a_{j}\right)=t_{j 1}+$ $\cdots+t_{j m}=\operatorname{deg}\left(\left(x_{j}\right)_{K_{l}}\right)-\operatorname{deg}\left(l b_{j}\right) \equiv 0(\bmod l), t_{j m}$ is uniquely determined as the least non-negative residue of $-\left(t_{j 1}+\cdots+t_{j, m-1}\right)$ modulo $l$; and so the number of $a_{j}$ does not exceed the number of ( $t_{j 1}, \cdots, t_{j, m-1}$ ) $\neq(0, \cdots, 0)$ with $0 \leqq t_{j i} \leqq l-1$ i.e. $l^{m-1}-1$. Therefore we have $l^{2 g}-l^{2 q_{0}} \leqq\left(\right.$ the number of $x_{j}$ of (*)-type) $\leqq\left(l^{m-1}-1\right) \cdot l^{2 g_{0}}$ and so

$$
\begin{equation*}
m \geqq 2\left(g-g_{0}\right)+1 \tag{1}
\end{equation*}
$$

Let $p$ be a prime divisor in $M$. Then there exists an element $x_{j}$ of (*)-type such that $\left(x_{j}\right)_{K_{l}}=\cdots+t p+\cdots$ with $t \neq 0(\bmod l)$. Let $f^{-1}(p)$ $=t_{1} P_{1}+\cdots+t_{h} P_{h}$ be the reduced expression, where $P_{i}$ is a prime divisor of $K$; then we have $l D_{j}=\left(x_{j}\right)_{K}=\cdots+t t_{1} P_{1}+\cdots+t t_{h} P_{h}+\cdots$. Hence $l$ divides $t_{j}$ and so the degree $n=t_{1}+\cdots+t_{n}$ of $K$ over $K_{l}$ and we have

$$
\begin{equation*}
\frac{t_{i}}{l} \geqq 1, \frac{n}{l} \geqq 1 . \tag{2}
\end{equation*}
$$

Moreover, denoting by $m\left(P_{i}\right)$ the differential exponent of $P_{i}$ for the extension $K / K_{l}$ (cf. [2]), we have

$$
\begin{equation*}
\sum_{i=1}^{n} m\left(P_{i}\right) \geqq n\left(1-\frac{1}{l}\right) . \tag{3}
\end{equation*}
$$

In fact, we have $\sum_{i} m\left(P_{i}\right) \geqq \sum_{i}\left(t_{i}-1\right)=n-h$ and, by (2), $h \leqq \sum_{i} \frac{t_{i}}{l}=\frac{n}{l}$. Therefore we have, by the formula of Hurwitz and by (1) and (3),

$$
\begin{aligned}
2 g-2 & \geqq n\left(2 g_{0}-2\right)+\left\{2\left(g-g_{0}\right)+1\right\} n\left(1-\frac{1}{l}\right) \\
& =\frac{n}{l}\left\{2(l-1) g+2 g_{0}-(l+1)\right\} .^{*)}
\end{aligned}
$$

Since $\frac{n}{l} \geqq 1, g_{0} \geqq 0$ and $2(l-1) g>l+1$, we have

$$
\begin{aligned}
& 2 g-2 \geqq 2(l-1) g-(l+1) \\
& 4 g-1 \geqq(2 g-1) l .
\end{aligned}
$$

and so
Consequently we have

$$
l \leqq \frac{4 g-1}{2 g-1}=2+\frac{1}{2 g-1}<3,
$$

which is a contradiction.
2) Next we consider the case where $K$ is not separable over $K_{l}$. Let $K^{\prime}$ be the maximal separable extension of $K_{l}$ in $K$. Then $K$ is purely inseparable over $K^{\prime}$ and the genus of $K^{\prime}$ is also $g$. Let $\left(x_{i}\right)_{K}$ be the divisor of $x_{i}$ in $K^{\prime}$ and $f^{\prime-1}$ the conorm mapping for the extension $K / K^{\prime}$. We have $f^{\prime-1}\left(\left(x_{i}\right)_{K^{\prime}}\right)=l D_{i}$ and so, taking the norm mapping $f^{\prime}$, we have $\left[K: K^{\prime}\right]\left(x_{i}\right)_{K^{\prime}}=l f^{\prime}\left(D_{i}\right)$. Since [ $\left.K: K^{\prime}\right]$ is a power of the characteristic of $k$ and is prime to $l$, we have $\left(x_{i}\right)_{K^{\prime}}=l D_{i}^{\prime}$ with some divisors $D_{i}^{\prime}$ in $K^{\prime}$. Then, by a similar argument as above, we can show that $D_{1}^{\prime}, \cdots, D_{N}^{\prime}\left(N=l^{2 g}\right)$ represent all the $l$-division points of $C\left(K^{\prime}\right)$. Hence $K_{l}=k\left(x_{1}, \cdots, x_{N}\right)$ is also one of the fields of $l$-division points of $K^{\prime}$. Since $K^{\prime}$ is separable over $K_{l}$, we have, by the first part of the proof, $K^{\prime}=K_{l}$ and so $K$ is purely inseparable over $K_{l}$.

Thus the proof is completed.
Finally we shall give three remarks.
Remark 1. Let $K_{n}$ be a field of $n$-division points of $K$ and $m$ a natural number dividing $n$. Then we can easily prove that there exists a field $K_{m}$ of $m$-division points of $K$ such that we have $K_{n} \supset K_{m}$. On the other hand, as in the first part of the proof, we can prove that if $K \neq K_{l^{n}}$ and $K$ is separable over $K_{l^{n}}$ ( $l$ is a prime number $\neq$ the characteristic $p$ of $k$ ) then $l^{n}$ divides the degree [ $K: K_{l^{n}}$ ]. Hence, combining with the result of Arima for $l=2$, we see that $K$ is purely inseparable over any field $K_{n}$ of $n$-division points of $K$, provided $n$ is divisible by a prime number $l(\neq p) \geqq 3$ or by $2^{3}$ (in the case $2 \neq p$ ).

Remark 2. When the characteristic $p$ of $k$ is positive, there occur, for the same prime number $l$, actually two cases: 1) $K=K_{l}$ and 2) $K \neq K_{l}$ ( $K / K_{l}$ is purely inseparable). We fix a divisor $A=P_{1}$ $+\cdots+P_{g}$ with $P_{i} \neq P_{j}(i \neq j)$ and take the divisors $D_{i}=B_{i}-A$ as the

[^0]representative divisors of $l$-division points $c_{i}$, where $B_{i}$ is a positive divisor of degree $g$. Then the field $K_{l}$ of $l$-division points of $K$ obtained by the choice of such representative divisors coincides with $K$. In fact, for a non-constant $x_{i}$, each coefficient of a prime divisor in the pole of $x_{i}$ is not divisible by $p$ and so $x_{i}^{\frac{1}{p}}$ is not in $K$. Hence $x_{i}$ is a separating element over $k$ of $K$ and so, as $K \supset K_{l} \supset k\left(x_{i}\right), K$ is separable over $K_{l}$, i.e. we have $K=K_{l}$. On the other hand, we consider $K^{\prime}=K^{p}$ and a field $K_{l}^{\prime}=k\left(y_{1}, \cdots, y_{N}\right)$ of $l$-division points of $K^{\prime}$ $\left(N=l^{2 q}\right)$. Then, denoting $\left(y_{i}\right)_{K^{\prime}}=l D_{i}^{\prime}$, we have $\left(y_{i}\right)_{K}=l f^{\prime-1}\left(D_{i}^{\prime}\right)$, where $f^{\prime-1}$ is the conorm mapping for the extension $K / K^{\prime}$. If $f^{\prime-1}\left(D_{i}^{\prime}\right)$ $\sim f^{\prime-1}\left(D_{j}^{\prime}\right)$, then $f^{\prime-1}\left(D_{i}^{\prime}-D_{j}^{\prime}\right)=(z)$ with some element $z$ in $K$. Then, taking the norm mapping $f^{\prime}$, we have $q\left(D_{i}^{\prime}-D_{j}^{\prime}\right)=\left(N_{K / K^{\prime}} z\right)$, where $q$ is a power of $p$. Hence we have $q\left(D_{i}^{\prime}-D_{j}^{\prime}\right) \sim 0$ and, as $l\left(D_{i}^{\prime}-D_{j}^{\prime}\right)$ $=\left(y_{i}\right)_{K^{\prime}}-\left(y_{j}\right)_{K^{\prime}} \sim 0$, we have $D_{i}^{\prime}-D_{j}^{\prime} \sim 0$, which is a contradiction. Hence $K_{l}^{\prime}=k\left(y_{1}, \cdots, y_{N}\right)$ is also one of the fields of $l$-division points of $K$ and we have $K \supseteqq K^{\prime} \supset K_{l}^{\prime}$.

Remark 3. From the results obtained above, we can show that $K$ has two systems of generators over $k$, which have the following properties: We fix a prime number $l$ which is $\geqq 3$ and different from the characteristic and we put $N=l^{2 g}$. 1) For given $g$ distinct prime divisors $P_{1}, \cdots, P_{g}$, there exist $N$ elements $x_{1}, \cdots, x_{N}$ of $K$ such that $K=k\left(x_{1}, \cdots, x_{N}\right)$ and the pole of $x_{j}$ has the form $l P_{j 1}+\cdots+l P_{j s}$, $P_{j i} \in\left\{P_{1}, \cdots, P_{g}\right\}$. 2) For a given prime divisor $P_{0}$, there exist $N$ elements $y_{1}, \cdots, y_{N}$ of $K$ such that $K=k\left(y_{1}, \cdots, y_{N}\right)$ and the pole of $y_{j}$ has the form $l t_{j} P_{0}$.
