# Estimates for the $X$-ray transform restricted to 2-manifolds 

M. Burak Erdoğan and Richard Oberlin

#### Abstract

We prove almost sharp mixed-norm estimates for the $X$-ray transform restricted to lines whose directions lie on certain well-curved two dimensional manifolds.

## 1. Introduction

The full X-ray transform, also known as the 1-plane transform, $X_{\text {full }}$, is an operator from the functions on $\mathbb{R}^{d}$ to the functions on $\mathcal{G}_{d}$, the space of all lines in $\mathbb{R}^{d}$. It is defined as

$$
X_{\text {full }} f(l)=\int_{l} f, \quad l \in \mathcal{G}_{d} .
$$

It is well-known $[2,20,14]$ that the optimal conjectured mixed-norm estimates for $X_{\text {full }}$ imply the Kakeya conjecture, which states that every compact subset of $\mathbb{R}^{d}$ containing a unit line segment in every direction must have Hausdorff dimension $d$.

Note that $\mathcal{G}_{d}$ is a $2 d-2$-dimensional manifold, thus $X_{\text {full }}$ is over-determined for $d \geq 3$, and it is of interest to consider its restrictions to lower dimensional subspaces of $\mathcal{G}_{d}$. We consider subspaces defined by restricting the set of directions to a lower dimensional submanifold of $S^{d-1}$. One particular example is the restriction of $X_{\text {full }}$ to the space of light rays (lines in $\mathbb{R}^{d}$ making a 45 degree angle with the plane $x_{d}=0$ ). In [21], Wolff obtained mixed-norm estimates for this operator in all dimensions (almost sharp in $\mathbb{R}^{3}$ and $\left.\mathbb{R}^{4}\right)$. Also see [17] for a simplified proof of Wolff's result. Almost sharp mixed-norm estimates are also known in the cases when the set of directions is given by a curve, see [9, 10].

[^0]In this paper, we consider the $X$-ray transform restricted to directions lying on a 2 -surface in $\mathbb{R}^{d-1}$ :

$$
z \rightarrow \theta(z)=\left(\theta_{1}(z), \ldots, \theta_{d-1}(z)\right)
$$

Specifically, let $f$ be a function on $\mathbb{R}^{d}, z \in \mathbb{R}^{2}$, and $y \in \mathbb{R}^{d-1}$. We define

$$
T^{\theta}[f](z, y)=\int_{0}^{1} f(\gamma(z, y, s)) d s
$$

where

$$
\gamma(z, y, s)=y+s\left(\theta(z)+e_{d}\right) .
$$

Here $e_{1}, \ldots, e_{d}$ is an orthonormal basis for $\mathbb{R}^{d}$ and we identify $\mathbb{R}^{d-1}$ with $\operatorname{span}\left(e_{1}, \ldots, e_{d-1}\right)$.

Letting $B \subset \mathbb{R}^{2}$ be a fixed ball, we have the Kakeya-order mixed-norm on the set of lines

$$
\left\|T^{\theta}[f]\right\|_{L^{q}\left(L^{r}\right)}=\left(\int_{B}\left(\int_{\mathbb{R}^{d-1}}\left|T^{\theta}[f](z, y)\right|^{r} d y\right)^{\frac{q}{r}} d z\right)^{\frac{1}{q}}
$$

and are interested in estimates

$$
\begin{equation*}
\left\|T^{\theta}[f]\right\|_{L^{q}\left(L^{r}\right)} \lesssim\|f\|_{L^{p}\left(\mathbb{R}^{d}\right)} . \tag{1.1}
\end{equation*}
$$

Let $s_{j}$ be the "minimum degree" of a collection of $j$ distinct monomials in two variables: $s_{1}, s_{2}=1 ; s_{3}, \ldots, s_{5}=2 ; s_{6}, \ldots, s_{9}=3 ; s_{10}, \ldots, s_{14}=4 ; \ldots$ Let $S_{n}=\sum_{j=1}^{n} s_{j}$. Then, for any smooth 2 -surface in $\mathbb{R}^{d-1}$, (1.1) may only hold if the following inequalities are satisfied

$$
\begin{align*}
& 1+\frac{d-1}{r} \geq \frac{d}{p}  \tag{1.2}\\
& \frac{2}{q}+\frac{S_{d-1}}{r} \geq \frac{S_{d-1}}{p} \\
& \frac{S_{d-1}}{r} \geq \frac{S_{d-1}-2}{p}
\end{align*}
$$

The first necessary condition above follows by applying $T^{\theta}$ to the characteristic function of a $\delta$-ball and taking $\delta$ to zero. Similarly, the second one follows by applying $T^{\theta}$ to the characteristic function of a parallelepiped with dimensions $1 \times \delta^{s_{1}} \times \delta^{s_{2}} \times \cdots \times \delta^{s_{d-1}}$ adapted to the cone of $\theta$ via an order $s_{d-1}$ Taylor expansion for $\theta$. Finally, the third one can be obtained by applying $T^{\theta}$ to the characteristic function of a disjoint union of $\sim \delta^{-2}$ parallelepipeds as above. Also note that (1.4) follows from (1.3) if we restrict ourself to the natural case $p \leq q$ as it was observed in [10].

We call a 2 -surface "well-curved", if the corresponding restricted $X$-ray transform satisfies (1.1) for all ( $p, q, r$ ) in the interior of the region determined by (1.2), (1.3), (1.4). We expect the following to be examples of well-curved 2 -surfaces in $\mathbb{R}^{d-1}$

| $d$ | $\theta(u, v)$ |
| :--- | :--- |
| 4 | $\left(u, v, u^{2}+v^{2}\right)$ |
| 5 | $\left(u, v, u^{2}-v^{2}, u v\right)$ |
| 6 | $\left(u, v, u^{2}, u v, v^{2}\right)$ |
| 7 | $\left(u, v, u^{2}, u v, v^{2}, u^{3}+v^{3}\right)$ |
| 8 | $\left(u, v, u^{2}, u v, v^{2}, u\left(u^{2}+v^{2}\right), v\left(u^{2}+v^{2}\right)\right)$ |
| 9 | $\left(u, v, u^{2}, u v, v^{2}, u^{3}+v^{3}, u^{2} v, u v^{2}\right)$ |

Note that the inequality (1.1) for critical exponents $(p, q, r)=\left(p_{\text {cr }}(d)\right.$, $\left.q_{\mathrm{cr}}(d), r_{\text {cr }}(d)\right)$ specified below

$$
\begin{aligned}
& p_{\text {cr }}=q_{\text {cr }}=1+\frac{2(d-1)}{S_{d-1}} \\
& r_{c r}=1+\frac{2 d}{S_{d-1}-2}
\end{aligned}
$$

implies (1.1) for all possible values of ( $p, q, r$ ) permitted by (1.2), (1.3), and (1.4) by interpolation with trivial estimates. It is important to note that

$$
p_{\text {cr }} \leq q_{\mathrm{cr}} \leq r_{\text {cr }} .
$$

To study these operators, we use the iterated $T^{*} T$ method from [5], also see $[6,18,7,8,13,15]$ for some related work. In [9] and [10], this method was extended to the mixed norm setting. Using a variation of the method from [9], we will prove (1.1) with ( $p, q, r$ ) arbitrarily close to $\left.p_{\text {cr }}(d), q_{\mathrm{cr}}(d), r_{\mathrm{cr}}(d)\right)$ for some surfaces $\theta$ (including the well-curved example surfaces above) when $d=4,5,7,8,9$. The case $d=4$ was already known to hold, as shown by Wolff [21]. When $d=6$, the method in [9] breaks down since the Jacobian is identically zero; However, by using the inflation argument from $[6,7]$, we are still able to obtain the almost $\operatorname{sharp} L^{p} \rightarrow L^{q}$ estimates.

The main difference between the method here and the method in [9] is the "localization" argument. In [9], the set of directions is one-dimensional and the mixed-norm estimates are obtained by reduction to the case where the directions are localized to and well distributed within a small interval. Higher dimensional localizations were used, within the context of $L^{p} \rightarrow L^{q}$
estimates, in [7]. There, the localization was performed with respect to parallelepipeds whose axes had varying direction and varying length. Here, in order to obtain mixed-norm estimates, it seems to be necessary to fix (according to the surface $\theta$ ) the directions of the axes (see Section 2). This method also gives sharp estimates for certain surfaces $\theta$ of dimension greater than 2 which are not "well-curved". However, it appears that a general result involving the mixed norm estimates is currently out of reach due to the complicated nature of the Jacobians.

In Appendix A, we present an extension of the method in [5] to the multilinear setting.

The second author would like to thank D. Oberlin for helpful conversations, including the suggestion of some of the model surfaces under consideration here.

## 2. Bilinear reduction

Since the operator $T$ is local and translation-invariant in a suitable sense, and $p \leq q \leq r$, we can assume that $f$ is supported in $B(0,1) \subset \mathbb{R}^{d}$. Also, since we are not considering endpoints, it suffices to establish the restricted weak-type inequality

$$
\begin{equation*}
\left\langle\chi_{F}, T\left[\chi_{E}\right]\right\rangle \lesssim|E|^{\frac{1}{p}}\left\|\chi_{F}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)} \tag{2.1}
\end{equation*}
$$

where $q^{\prime}$ and $r^{\prime}$ are dual to the exponents $q$ and $r$, and $E \subset B(0,1) \subset \mathbb{R}^{d}$, $F \subset B \times \mathbb{R}^{d-1}$, and $B$ is a fixed ball in $\mathbb{R}^{2}$. Note that (2.1) is equivalent to (for $1<p<\infty$ )

$$
\left|\left\{x: T^{*}\left[\chi_{F}\right] \geq \beta\right\}\right| \lesssim \beta^{-p^{\prime}}\left\|\chi_{F}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)}^{p^{\prime}}
$$

Therefore, in (2.1), we can assume that for some $0<\tilde{\beta} \lesssim 1$, and for each $x \in E$,

$$
\begin{equation*}
\tilde{\beta} \leq T^{*}\left[\chi_{F}\right] \leq 2 \tilde{\beta} \tag{2.2}
\end{equation*}
$$

One may calculate that for $x \in \mathbb{R}^{d}$ and functions $g$ on $\mathbb{R}^{2} \times \mathbb{R}^{d-1}$

$$
T^{*}[g](x)=\int_{B} g\left(\gamma^{*}(x, z)\right) d z
$$

where

$$
\gamma^{*}(x, z)=\left(z, \operatorname{proj}_{\mathbb{R}^{d-1}}(x)-\left\langle x, e_{d}\right\rangle \theta(z)\right)
$$

Note that $T^{*}[g](x)$ is an averaging of $g$ over the set of lines passing through $x$.

### 2.1. Localization

The following lemma is a variant of certain lemmas found, for example, in [21], [18], and [9].

For $R_{1}, R_{2}>0, y \in \mathbb{R}^{2}$, and linearly independent $w_{1}, w_{2} \in \mathbb{R}^{2}$, we consider the parallelogram

$$
P_{w_{1}, w_{2}}\left(y, R_{1}, R_{2}\right)=\left\{y+s_{1} w_{1}+s_{2} w_{2}:\left(s_{1}, s_{2}\right) \in\left[-R_{1}, R_{1}\right] \times\left[-R_{2}, R_{2}\right]\right\} .
$$

Lemma 2.1. Let $0<\epsilon<1$, and let $B \subset \mathbb{R}^{2}$ be a fixed ball. Then, for every $G \subset B$ with $|G|>0$, there exist $R_{1}, R_{2}$ with $|G|^{1+\epsilon} \lesssim R_{1}, R_{2} \lesssim 1$ and $y \in \mathbb{R}^{2}$ such that

$$
\begin{equation*}
\left|G \cap P_{w_{1}, w_{2}}\left(y, R_{1}, R_{2}\right)\right| \gtrsim|G|^{1+\epsilon} \tag{2.3}
\end{equation*}
$$

and such that for every $y^{\prime}$ and $R_{1}^{\prime} R_{2}^{\prime}<R_{1} R_{2}$

$$
\begin{equation*}
\left|G \cap P_{w_{1}, w_{2}}\left(y^{\prime}, R_{1}^{\prime}, R_{2}^{\prime}\right)\right|<\left(\frac{R_{1}^{\prime} R_{2}^{\prime}}{R_{1} R_{2}}\right)^{\frac{\epsilon}{2}}\left|G \cap P_{w_{1}, w_{2}}\left(y, R_{1}, R_{2}\right)\right| . \tag{2.4}
\end{equation*}
$$

The implicit constants above may depend on $B, \epsilon, w_{1}, w_{2}$.
Proof. Choose $\bar{R}_{1}, \bar{R}_{2} \lesssim 1$ and $\bar{y}$ so that $B \subset P_{w_{1}, w_{2}}\left(\bar{y}, \bar{R}_{1}, \bar{R}_{2}\right)$, and let $\epsilon^{\prime}=\frac{\epsilon}{1+\epsilon}$. Then

$$
\left|G \cap P_{w_{1}, w_{2}}\left(\bar{y}, \bar{R}_{1}, \bar{R}_{2}\right)\right| \geq\left(\frac{\bar{R}_{1} \bar{R}_{2}}{\bar{R}_{1} \bar{R}_{2}}\right)^{\epsilon^{\prime}}|G|
$$

Let $R_{1}, R_{2}$ be chosen with $R_{1} R_{2}$ minimal so that there exists a $y$ with

$$
\left|G \cap P_{w_{1}, w_{2}}\left(y, R_{1}, R_{2}\right)\right| \geq\left(\frac{R_{1} R_{2}}{\bar{R}_{1} \bar{R}_{2}}\right)^{\epsilon^{\prime}}|G| .
$$

Clearly

$$
\begin{equation*}
R_{1} R_{2} \gtrsim|G|^{\frac{1}{1-\epsilon}}=|G|^{1+\epsilon} \tag{2.5}
\end{equation*}
$$

By the minimality of $R_{1} R_{2}$, and the fact that $G \subset B$, we also have $R_{1}, R_{2} \lesssim 1$ and so $R_{1}, R_{2} \gtrsim|G|^{1+\epsilon}$. Again from (2.5),

$$
\left|G \cap P_{w_{1}, w_{2}}\left(y, R_{1}, R_{2}\right)\right| \gtrsim\left(\frac{|G|^{\frac{1}{1-\epsilon}}}{\bar{R}_{1} \bar{R}_{2}}\right)^{\epsilon^{\prime}}|G| \gtrsim|G|^{1+\epsilon} .
$$

The minimality of $R_{1}, R_{2}$ then guarantees that for every $y^{\prime}$ and $R_{1}^{\prime} R_{2}^{\prime}<$ $R_{1} R_{2}$, we have

$$
\begin{aligned}
\left|G \cap P_{w_{1}, w_{2}}\left(y^{\prime}, R_{1}^{\prime}, R_{2}^{\prime}\right)\right| & <\left(\frac{R_{1}^{\prime} R_{2}^{\prime}}{\bar{R}_{1} \bar{R}_{2}}\right)^{\epsilon^{\prime}}|G| \\
& \leq\left(\frac{R_{1}^{\prime} R_{2}^{\prime}}{R_{1} R_{2}}\right)^{\epsilon^{\prime}}\left|G \cap P_{w_{1}, w_{2}}\left(y, R_{1}, R_{2}\right)\right| \\
& \leq\left(\frac{R_{1}^{\prime} R_{2}^{\prime}}{R_{1} R_{2}}\right)^{\frac{\epsilon}{2}}\left|G \cap P_{w_{1}, w_{2}}\left(y, R_{1}, R_{2}\right)\right| .
\end{aligned}
$$

### 2.2. Decomposition

We now decompose $E$ with respect to the parallelograms obtained from Lemma 2.1. Fix $w_{1}, w_{2}$ depending on $d$ (and in particular depending on the surface specified for $d$ ).

For each $x \in E$, let

$$
G_{x}=\left\{z: \gamma^{*}(x, z) \in F\right\} .
$$

We have $G_{x}$ contained in the fixed ball $B$ and $\left|G_{x}\right|=T^{*}\left[\chi_{F}\right](x) \approx \tilde{\beta}$. Applying Lemma 2.1 with $G=G_{x}$ and $\epsilon>0$ (which will be determined later), we obtain $R_{1, x}, R_{2, x}$ and $y_{x}$ satisfying (2.3) and (2.4). Note that for each $R_{i, x}$

$$
\tilde{\beta}^{1+\epsilon} \lesssim R_{i, x} \lesssim 1
$$

and so, by absorbing a possible factor of $\approx|\log (\tilde{\beta})|^{2}$, it suffices to show that

$$
\begin{equation*}
\left\langle T^{*}\left[\chi_{F}\right], \chi_{E^{\prime}}\right\rangle \lesssim \tilde{\beta}^{\epsilon}\left|E^{\prime}\right| \frac{1}{p}\left\|\chi_{F}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)} \tag{2.6}
\end{equation*}
$$

where $R_{i} \lesssim R_{i, x} \leq R_{i}$ on $E^{\prime}$.
Cover $\mathbb{R}^{2}$ by parallelograms $P_{w_{1}, w_{2}}\left(y_{j}, R_{1}, R_{2}\right)$ which have measure-zero overlap. For each $j$, let

$$
F_{j}=F \cap\left(P_{w_{1}, w_{2}}\left(y_{j}, 2 R_{1}, 2 R_{2}\right) \times \mathbb{R}^{d-1}\right)
$$

and

$$
E_{j}=\left\{x \in E^{\prime}: y_{x} \in P_{w_{1}, w_{2}}\left(y_{j}, R_{1}, R_{2}\right)\right\} .
$$

Then

$$
\begin{equation*}
\left\langle T^{*}\left[\chi_{F}\right], \chi_{E^{\prime}}\right\rangle \leq \sum_{j}\left\langle T^{*}\left[\chi_{F}\right], \chi_{E_{j}}\right\rangle \lesssim \tilde{\beta}^{-\epsilon} \sum_{j}\left\langle T^{*}\left[\chi_{F_{j}}\right], \chi_{E_{j}}\right\rangle \tag{2.7}
\end{equation*}
$$

where the second inequality follows from (2.3) and the fact that $P_{w_{1}, w_{2}}\left(y_{x}\right.$, $\left.R_{1}, R_{2}\right) \subset P_{w_{1}, w_{2}}\left(y_{j}, 2 R_{1}, 2 R_{2}\right)$ if $y_{x} \in P_{w_{1}, w_{2}}\left(y_{j}, R_{1}, R_{2}\right)$. In Sections 3 and 4 , we prove the estimate

$$
\begin{equation*}
\left\langle T^{*}\left[\chi_{F_{j}}\right], \chi_{E_{j}}\right\rangle \lesssim \tilde{\beta}^{2 \epsilon}\left|E_{j}\right|^{\frac{1}{p}}\left\|\chi_{F_{j}}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)} . \tag{2.8}
\end{equation*}
$$

It thus follows from Hölder's inequality that

$$
\begin{align*}
\sum_{j}\left\langle T^{*}\left[\chi_{F_{j}}\right], \chi_{E_{j}}\right\rangle & \lesssim \tilde{\beta}^{2 \epsilon} \sum_{j}\left|E_{j}\right|^{\frac{1}{p}}\left\|\chi_{F_{j}}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)}  \tag{2.9}\\
& \leq \tilde{\beta}^{2 \epsilon}\left(\sum_{j}\left|E_{j}\right|\right)^{\frac{1}{p}}\left(\sum_{j}\left\|\chi_{F_{j}}\right\|_{L^{q^{\prime}\left(L^{r^{\prime}}\right)}}^{p^{\prime}}\right)^{\frac{1}{p^{\prime}}}
\end{align*}
$$

We have $p^{\prime} \geq q^{\prime}$ and so

$$
\begin{align*}
\left(\sum_{j}\left|E_{j}\right|\right)^{\frac{1}{p}}\left(\sum_{j}\left\|\chi_{F_{j}}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)}^{p^{\prime}}\right)^{\frac{1}{p^{\prime}}} & \lesssim\left(\sum_{j}\left|E_{j}\right|\right)^{\frac{1}{p}}\left(\sum_{j}\left\|\chi_{F_{j}}\right\|_{L^{q^{\prime}\left(L^{r^{\prime}}\right)}}^{q^{\prime}}\right)^{\frac{1}{q^{\prime}}}  \tag{2.10}\\
& \lesssim\left|E^{\prime}\right|^{\frac{1}{p}}\left\|\chi_{F}\right\|_{L^{q^{\prime}\left(L^{r^{\prime}}\right)}}
\end{align*}
$$

where the last inequality follows from the finite overlap of the $P_{w_{1}, w_{2}}\left(y_{j}, 2 R_{1}\right.$, $2 R_{2}$ ). Combining (2.7), (2.9), and (2.10), we obtain (2.6).

## 3. Main estimate

We now prove

$$
\left\langle T^{*}\left[\chi_{F}\right], \chi_{E}\right\rangle \lesssim \tilde{\beta}^{2 \epsilon}|E|^{\frac{1}{p}}\left\|\chi_{F}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)}
$$

for $(p, q, r)$ close to $\left(p_{\text {cr }}(d), q_{\mathrm{cr}}(d), r_{\mathrm{cr}}(d)\right)$ (where $\epsilon>0$ depends on $\left.r_{\mathrm{cr}}(d)-r\right)$, under the assumptions:
I) For some $y \in \mathbb{R}^{2}$ and $\tilde{\beta}^{1+\epsilon} \lesssim R_{1}, R_{2} \lesssim 1$

$$
\begin{equation*}
F \subset P_{w_{1}, w_{2}}\left(y, 2 R_{1}, 2 R_{2}\right) \times \mathbb{R}^{d-1} \tag{3.1}
\end{equation*}
$$

II) For each $x \in E$,

$$
\begin{equation*}
\tilde{\beta}^{1+\epsilon} \lesssim T^{*}\left[\chi_{F}\right](x) \lesssim \tilde{\beta} \tag{3.2}
\end{equation*}
$$

III) For each $x \in E, y^{\prime} \in \mathbb{R}^{2}$, and $R_{1}^{\prime} R_{2}^{\prime}<R_{1} R_{2}$,

$$
\begin{equation*}
T^{*}\left[\chi_{F \cap\left(P_{w_{1}, w_{2}}\left(y^{\prime}, R_{1}^{\prime}, R_{2}^{\prime}\right) \times \mathbb{R}^{d-1}\right)}\right](x) \lesssim\left(\frac{R_{1}^{\prime} R_{2}^{\prime}}{R_{1} R_{2}}\right)^{\frac{\epsilon}{2}} T^{*}\left[\chi_{F}\right](x) \tag{3.3}
\end{equation*}
$$

By Section 2, this suffices to prove (1.1).
Absorbing a possible factor of $\approx|\log (\tilde{\beta})|$, we assume without loss of generality that $T^{*}\left[\chi_{F}\right] \approx \beta^{\prime}$ on $E$ where $\tilde{\beta}^{1+\epsilon} \lesssim \beta^{\prime} \lesssim \tilde{\beta}$.

The quantities

$$
\alpha=\frac{\left\langle T^{*}\left[\chi_{F}\right], \chi_{E}\right\rangle}{|F|} \quad \text { and } \quad \beta=\frac{\left\langle T^{*}\left[\chi_{F}\right], \chi_{E}\right\rangle}{|E|}
$$

will appear throughout this section. Of course $\beta \approx \beta^{\prime}$.

### 3.1. Iterated maps and parameter-space towers

Let $n$ be the integer satisfying $d+1 \leq 3 n \leq d+3$. Fix a line $\left(z_{0}, y_{0}\right)$ to be specified below, and define the maps

$$
\Phi_{1}\left(t_{1}\right)=\gamma\left(z_{0}, y_{0}, t_{1}\right)
$$

and

$$
\Phi_{1}^{*}\left(t_{1}, z_{1}\right)=\gamma^{*}\left(\Phi_{1}\left(t_{1}\right), z_{1}\right) .
$$

For $i=2, \ldots, n$ define the iterated maps

$$
\Phi_{i}\left(t_{1}, z_{1}, \ldots, t_{i-1}, z_{i-1}, t_{i}\right)=\gamma\left(\Phi_{i-1}^{*}\left(t_{1}, z_{1}, \ldots, t_{i-1}, z_{i-1}\right), t_{i}\right)
$$

and

$$
\Phi_{i}^{*}\left(t_{1}, z_{1}, \ldots, t_{i}, z_{i}\right)=\gamma^{*}\left(\Phi_{i}\left(t_{1}, z_{1}, \ldots, t_{i-1}, z_{i-1}, t_{i}\right), z_{i}\right)
$$

For any $\Omega \subset\left(\mathbb{R}^{1} \times \mathbb{R}^{2}\right)^{n}$ and $1 \leq i \leq n$, let

$$
\begin{aligned}
\Omega_{i}^{*} & =\left\{\left(t_{1}, z_{1}, \ldots, t_{i}, z_{i}\right):\left(t_{1}, z_{1}, \ldots, t_{n}, z_{n}\right) \in \Omega\right\}, \\
\Omega_{i} & =\left\{\left(t_{1}, z_{1}, \ldots, t_{i-1}, z_{i-1}, t_{i}\right):\left(t_{1}, z_{1}, \ldots, t_{n}, z_{n}\right) \in \Omega\right\} .
\end{aligned}
$$

Definition 3.1. Let $\bar{\alpha}, \bar{\beta}>0$, and $\Omega \subset\left(\mathbb{R}^{1} \times \mathbb{R}^{2}\right)^{n}$. We say that $\Omega$ is an $(\bar{\alpha}, \bar{\beta})$ tower if there exists a $\left(z_{0}, y_{0}\right) \in F$ so that the following conditions hold.

$$
\begin{equation*}
\left|\Omega_{1}\right| \geq 2^{-4 n} \bar{\alpha} \tag{3.4}
\end{equation*}
$$

For $1<i \leq n$

$$
\begin{equation*}
\left|s:\left(\omega^{*}, s\right) \in \Omega_{i}\right| \geq 2^{-4 n} \bar{\alpha} \text { for every } \omega^{*} \in \Omega_{i-1}^{*} \tag{3.5}
\end{equation*}
$$

For $1 \leq i \leq n$

$$
\begin{gather*}
\Phi_{i}(\omega) \in E \text { for every } \omega \in \Omega_{i}  \tag{3.6}\\
\left|z:(\omega, z) \in \Omega_{i}^{*}\right| \geq 2^{-4 n} \bar{\beta} \text { for every } \omega \in \Omega_{i}  \tag{3.7}\\
\Phi_{i}^{*}\left(\omega^{*}\right) \in F \text { for every } \omega^{*} \in \Omega_{i}^{*} . \tag{3.8}
\end{gather*}
$$

The following is essentially Lemma 1 of [5].
Lemma 3.2. There exists an $(\alpha, \beta)$ tower.

### 3.2. Change of variables

Let $\Omega$ be an $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower where $\alpha^{\prime} \gtrsim \alpha$ and $\beta^{\prime} \gtrsim \beta$.
Fix $t_{1} \in \Omega_{1}$. If $3 n=d+3$ let

$$
\Pi=\left\{\left(z_{1}, t_{2}, z_{2}, \ldots, t_{n-1}, z_{n-1}, t_{n}\right):\left(t_{1}, z_{1}, \ldots, t_{n}, z_{n}\right) \in \Omega\right\}
$$

if $3 n=d+2$ let

$$
\Pi=\left\{\left(z_{1}, t_{2}, z_{2}, \ldots, t_{n}, z_{n}\right):\left(t_{1}, z_{1}, \ldots, t_{n}, z_{n}\right) \in \Omega\right\},
$$

and if $3 n=d+1$ let

$$
\Pi=\Omega
$$

Set $\Phi=\Phi_{n}\left(t_{1}, \cdot\right)$ if $3 n=d+3, \Phi=\Phi_{n}^{*}\left(t_{1}, \cdot\right)$ if $3 n=d+2$, and $\Phi=\Phi_{n}^{*}$ if $3 n=d+1$.

Then

$$
\Phi: \Pi \rightarrow E
$$

if $3 n=d+3$ and

$$
\Phi: \Pi \rightarrow F
$$

if $3 n=d+2, d+1$.
From Bezout's theorem, these mappings are generically finite-to-one. Thus,

$$
\begin{equation*}
|E| \gtrsim \int_{\Pi} J(\omega) d \omega \tag{3.9}
\end{equation*}
$$

if $3 n=d+3$ where $J=\left|\operatorname{det}\left(\partial \Phi / \partial u_{1}, v_{1}, \ldots, t_{n}\right)\right|$, and

$$
\begin{equation*}
|F| \gtrsim \int_{\Pi} J(\omega) d \omega \tag{3.10}
\end{equation*}
$$

if $3 n=d+1, d+2$ where

$$
J=\left|\operatorname{det}\left(\partial \Phi / \partial u_{1}, v_{1}, \ldots, t_{n}, u_{n}, v_{n}\right)\right| \text { if } 3 n=d+2
$$

and

$$
J=\left|\operatorname{det}\left(\partial \Phi / \partial t_{1}, u_{1}, v_{1}, \ldots, t_{n}, u_{n}, v_{n}\right)\right| \text { if } 3 n=d+1
$$

Above, we write $z_{i}=\left(u_{i}, v_{i}\right)$.
In Section 4, we show that $\Omega$ may be chosen so that

$$
\begin{equation*}
|J| \gtrsim \alpha^{k_{d}} \beta^{l_{d}} R_{1} R_{2} \tag{3.11}
\end{equation*}
$$

on $\Omega$ where $k_{d}$ and $l_{d}$ are given by

$$
k_{d}=2(n-1), \quad l_{d}=\frac{S_{d-1}}{2}-n .
$$

Since $\Omega$ is an $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower with $\alpha^{\prime} \gtrsim \alpha$, and $\beta^{\prime} \gtrsim \beta$, we have

$$
\begin{array}{ll}
|\Pi| \gtrsim \alpha^{n-1} \beta^{n-1}, & \text { if } 3 n=d+3, \\
|\Pi| \gtrsim \alpha^{n-1} \beta^{n}, & \text { if } 3 n=d+2, \\
|\Pi| \gtrsim \alpha^{n} \beta^{n}, & \text { if } 3 n=d+1 .
\end{array}
$$

It thus follows from (3.9), (3.10), (3.11), and the definitions of $\alpha$ and $\beta$ that

$$
\begin{equation*}
R_{1} R_{2}\left\langle\chi_{F}, T\left[\chi_{E}\right]\right\rangle^{\frac{S_{d-1}}{2}+d-1} \lesssim|E|^{\frac{S_{d-1}}{2}}|F|^{d} . \tag{3.12}
\end{equation*}
$$

From (3.1) and Hölder's inequality, it follows that

$$
\begin{equation*}
\left(\frac{|F|}{\left(R_{1} R_{2}\right)^{1-\frac{r^{\prime}}{q^{\prime}}}}\right)^{\frac{1}{r^{\prime}}} \lesssim\left\|\chi_{F}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)} \tag{3.13}
\end{equation*}
$$

Thus, combining (3.12) and (3.13), we obtain

$$
\left\langle\chi_{F}, T\left[\chi_{E}\right]\right\rangle \lesssim|E|^{\frac{1}{p \operatorname{cr}}}\left\|\chi_{F}\right\|_{L^{g_{\mathrm{cr}}^{\prime}\left(L^{r_{c r}^{\prime}}\right)}}
$$

This implies that

$$
\left\langle\chi_{F}, T\left[\chi_{E}\right]\right\rangle \lesssim \beta^{2 \epsilon}|E|^{\frac{1}{p}}\left\|\chi_{F}\right\|_{L^{q^{\prime}}\left(L^{r^{\prime}}\right)}
$$

where ( $p, q, r$ ) are given by an arbitrarily small interpolation of ( $p_{\mathrm{cr}}, q_{\mathrm{cr}}, r_{\mathrm{cr}}$ ) with $(1,1,1)$.

## 4. Lower bounds for the Jacobians

Let $\Omega^{0}$ be the $(\alpha, \beta)$ tower guaranteed by Lemma 3.2. For any fixed $t_{1}, \ldots, t_{i}$,

$$
\left|\left\{t: \min _{j=1, \ldots, i}\left|t-t_{j}\right| \ll \alpha\right\}\right| \ll \alpha .
$$

Thus, by induction, one may find an $\left(\alpha^{\prime}, \beta\right)$ tower $\Omega^{1} \subset \Omega^{0}$, with $\alpha^{\prime} \gtrsim \alpha$ so that $\left|t_{i}-t_{j}\right| \gtrsim \alpha$ for $\left(t_{1}, z_{1}, \ldots, t_{n}, z_{n}\right) \in \Omega^{1}$ and $1 \leq i<j \leq n$.

Additional refinements of $\Omega^{1}$ needed to bound the Jacobian will have to be tailored to the individual 2 -surface in question. However, we will use the following lemma repeatedly.

Lemma 4.1. Let $0<C<1, \bar{\alpha}>0$, and let $\Omega$ be an $(\bar{\alpha}, C \beta)$ tower. Let $1 \leq i \leq n$, and let $\left\{P_{w_{1}, w_{2}}\left(y_{\omega}, R_{1}^{\prime}, R_{2}^{\prime}\right)\right\}_{\omega \in \Omega_{i}}$ be a family of parallelograms with $R_{1}^{\prime} R_{2}^{\prime} \ll R_{1} R_{2}(C)^{\frac{2}{\epsilon}}$. Then

$$
\Omega^{\prime}=\left\{\left(\omega, z_{i}, \ldots, t_{n}, z_{n}\right) \in \Omega: z_{i} \notin P_{w_{1}, w_{2}}\left(y_{\omega}, R_{1}^{\prime}, R_{2}^{\prime}\right)\right\}
$$

is an $\left(\bar{\alpha}, \frac{1}{2} C \beta\right)$ tower.
Proof. It suffices to check that for each $\omega \in \Omega_{1}$,

$$
\left|\left\{z_{i} \notin P_{w_{1}, w_{2}}\left(y_{\omega}, R_{1}^{\prime}, R_{2}^{\prime}\right):\left(\omega, z_{i}, \ldots, t_{n}, z_{n}\right) \in \Omega\right\}\right| \geq 2^{-4 n} \frac{1}{2} C \beta
$$

which follows from

$$
\begin{equation*}
\left|\left\{z_{i} \in P_{w_{1}, w_{2}}\left(y_{\omega}, R_{1}^{\prime}, R_{2}^{\prime}\right):\left(\omega, z_{i}, \ldots, t_{n}, z_{n}\right) \in \Omega\right\}\right|<2^{-4 n} \frac{1}{2} C \beta . \tag{4.1}
\end{equation*}
$$

To see (4.1), note that, from (3.8), we have
$\left\{z_{i} \in P_{w_{1}, w_{2}}\left(y_{\omega}, R_{1}^{\prime}, R_{2}^{\prime}\right):\left(\omega, z_{i}, \ldots, t_{n}, z_{n}\right) \in \Omega\right\} \subset\left\{z_{i}: \gamma^{*}\left(\Phi_{i}(\omega), z_{i}\right) \in F\right\}$.

But, from (3.6), we have $\Phi_{i}(\omega) \in E$ and so from (3.3)

$$
\left|\left\{z_{i}: \gamma^{*}\left(\Phi_{i}(\omega), z_{i}\right) \in F\right\}\right| \lesssim\left(\frac{R_{1}^{\prime} R_{2}^{\prime}}{R_{1} R_{2}}\right)^{\frac{\epsilon}{2}} \beta^{\prime}
$$

Since $\beta^{\prime} \lesssim \beta$, we thus have (4.1) from our choice of $R_{1}^{\prime} R_{2}^{\prime}$.

### 4.1. The case $3 n=d+1$

One may calculate that for $\omega=\left(t_{1}, z_{1}, \ldots, t_{n}, z_{n}\right)$ and $z_{i}=\left(u_{i}, v_{i}\right)$

$$
\Phi(\omega)=\left(z_{n}, y_{0}+\sum_{i=1}^{n} t_{i}\left(\theta\left(z_{i-1}\right)-\theta\left(z_{i}\right)\right)\right) .
$$

Thus,

$$
J=\left|\operatorname{det}\left(\partial \Phi / \partial t_{1}, u_{1}, v_{1}, \ldots, t_{n}, u_{n}, v_{n}\right)\right|=J_{t} \cdot J_{z}
$$

where

$$
\begin{gather*}
J_{t}=\prod_{i=1}^{n-1}\left(t_{i+1}-t_{i}\right)^{2}, \quad \text { and }  \tag{4.2}\\
J_{z}=\mid \operatorname{det}\left(\theta_{u}\left(z_{1}\right), \theta_{v}\left(z_{1}\right), \ldots, \theta_{u}\left(z_{n-1}\right), \theta_{v}\left(z_{n-1}\right),\right.  \tag{4.3}\\
\left.\theta\left(z_{0}\right)-\theta\left(z_{1}\right), \ldots, \theta\left(z_{n-1}\right)-\theta\left(z_{n}\right)\right) \mid .
\end{gather*}
$$

Above, we denote $\theta_{u}=\frac{\partial \theta}{\partial u}$ and $\theta_{v}=\frac{\partial \theta}{\partial v}$.
On $\Omega^{1}$, we have $J_{t} \gtrsim \alpha^{2(n-1)}$. Thus, it remains to find an ( $\alpha^{\prime}, \beta^{\prime}$ ) tower $\Omega \subset \Omega^{1}$ with $J_{z} \gtrsim R_{1} R_{2} \beta^{l_{d}}$ on $\Omega$ and $\beta^{\prime} \gtrsim \beta$.

### 4.1.1. $d=5$

We now work under the assumption that $d=5$ and that $\theta$ is of the form

$$
\theta(u, v)=(u, v, \bar{\theta}(u, v)) .
$$

We may then simplify (4.3) to

$$
\begin{aligned}
& J_{z}=\mid \operatorname{det}\left(\bar{\theta}\left(z_{0}\right)-\bar{\theta}\left(z_{1}\right)-\left(u_{0}-u_{1}\right) \bar{\theta}_{u}\left(z_{1}\right)-\left(v_{0}-v_{1}\right) \bar{\theta}_{v}\left(z_{1}\right),\right. \\
& \left.\quad \bar{\theta}\left(z_{2}\right)-\bar{\theta}\left(z_{1}\right)-\left(u_{2}-u_{1}\right) \bar{\theta}_{u}\left(z_{1}\right)-\left(v_{2}-v_{1}\right) \bar{\theta}_{v}\left(z_{1}\right)\right) \mid .
\end{aligned}
$$

Assuming that the entries in $\bar{\theta}$ are polynomials of degree 2 or less, this simplifies to

$$
J_{z}=\left|\operatorname{det}\left(\frac{\bar{u}_{0}^{2} \bar{\theta}_{u u}}{2}+\frac{\bar{v}_{0}^{2} \bar{\theta}_{v v}}{2}+\bar{u}_{0} \bar{v}_{0} \bar{\theta}_{u v}, \frac{\bar{u}_{2}^{2} \bar{\theta}_{u u}}{2}+\frac{\bar{v}_{2}^{2} \bar{\theta}_{v v}}{2}+\bar{u}_{2} \bar{v}_{2} \bar{\theta}_{u v}\right)\right|
$$

where

$$
\bar{z}_{0}=z_{1}-z_{0}, \bar{z}_{2}=z_{2}-z_{1} .
$$

After some algebra, we obtain

$$
J_{z}=\left|\left(\bar{u}_{0}, \bar{v}_{0}\right)\left(\begin{array}{ll}
0 & 1  \tag{4.4}\\
-1 & 0
\end{array}\right)\binom{\bar{u}_{2}}{\bar{v}_{2}}\right| \cdot\left|\left(\bar{u}_{0}, \bar{v}_{0}\right)\left(\begin{array}{cc}
A & \frac{B}{2} \\
\frac{B}{2} & C
\end{array}\right)\binom{\bar{u}_{2}}{\bar{v}_{2}}\right|
$$

where

$$
A=\frac{1}{2} \operatorname{det}\left(\bar{\theta}_{u u}, \bar{\theta}_{u v}\right), B=\frac{1}{2} \operatorname{det}\left(\bar{\theta}_{u u}, \bar{\theta}_{v v}\right), C=\frac{1}{2} \operatorname{det}\left(\bar{\theta}_{u v}, \bar{\theta}_{v v}\right) .
$$

We need the following lemma to further refine the parameter space tower.
Lemma 4.2. Let $A, B, C \in \mathbb{R}$ satisfy $B^{2}-4 A C \neq 0$, let $w_{1}$, $w_{2}$ be chosen, as specified below, according to $A, B, C$, let $0 \leq i<j \leq n$ and let $\Omega$ be an $\alpha^{\prime}, \beta^{\prime}$ tower with $\beta^{\prime} \gtrsim \beta$. Then, there is an $\left(\alpha^{\prime}, \beta^{\prime \prime}\right)$ tower $\Omega^{\prime} \subset \Omega$ with $\beta^{\prime \prime} \gtrsim \beta^{\prime}$ so that

$$
\left|Q_{i, j}\right| \gtrsim R_{1} R_{2}
$$

on $\Omega^{\prime}$ where

$$
Q_{i, j}\left(t_{1}, \ldots, z_{n}\right):=A\left(u_{j}-u_{i}\right)^{2}+B\left(u_{j}-u_{i}\right)\left(v_{j}-v_{i}\right)+C\left(v_{j}-v_{i}\right)^{2} .
$$

Proof. Let $z=z_{j}-z_{i}$. Assume first that $B^{2}-4 A C>0$.
If $A \neq 0$, we have

$$
Q_{i, j}=A\left(u-D_{+} v\right)\left(u-D_{-} v\right)
$$

where

$$
D_{+}=\frac{-B+\sqrt{B^{2}-4 A C}}{2 A}, \text { and } D_{-}=\frac{-B-\sqrt{B^{2}-4 A C}}{2 A} .
$$

Then taking $w_{1}=\left(D_{+}, 1\right)$ and $w_{2}=\left(D_{-}, 1\right)$ we may apply Lemma 4.1 twice to find $\Omega^{\prime}$ with $\left|u-D_{+} v\right| \gtrsim R_{2}$ and $\left|u-D_{-} v\right| \gtrsim R_{1}$ on $\Omega^{\prime}$.

If $A=0$, we have $B \neq 0$ and

$$
Q_{i, j}=v(B u+C v) .
$$

Then taking $w_{1}=(1,0), w_{2}=(-C, B)$, we may apply Lemma 4.1 twice to find $\Omega^{\prime}$ with $|v| \gtrsim R_{2}$ and $|B u+C v| \gtrsim R_{1}$ on $\Omega^{\prime}$.

If $B^{2}-4 A C<0$

$$
\left|Q_{i, j}\right|=|v|^{2}\left|A\left(\frac{u}{v}\right)^{2}+B \frac{u}{v}+C\right| \geq|v|^{2}\left|\frac{B^{2}-4 A C}{4 A}\right| .
$$

Similarly $\left|Q_{i, j}\right| \gtrsim|u|^{2}$, and thus $\left|Q_{i, j}\right| \gtrsim|z|$. Then taking any $w_{1}, w_{2}$ we may apply Lemma 4.1 twice to find $\Omega^{\prime}$ with $|z| \gtrsim \max \left(R_{1}, R_{2}\right)^{2}$ on $\Omega^{\prime}$.

We now assume the non-degeneracy condition (which is equivalent to the condition from [4], as was pointed out to the second author by D. Oberlin) $B^{2}-4 A C \neq 0$. From Lemma 4.2, we may find an $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower $\Omega^{2} \subset \Omega^{1}$ with $\beta^{\prime} \gtrsim \beta$ so that

$$
Q\left(\bar{z}_{0}\right) \gtrsim R_{1} R_{2}
$$

for $\left(z_{0}, z_{1}\right) \in \Omega^{2}$ where

$$
Q\left(\bar{z}_{0}\right)=\left|\left(\bar{u}_{0}, \bar{v}_{0}\right)\left(\begin{array}{cc}
A & \frac{B}{2} \\
\frac{B}{2} & C
\end{array}\right)\binom{\bar{u}_{0}}{\bar{v}_{0}}\right| .
$$

Choose $i \neq j \in\{1,2\}$ so that $R_{i} \geq R_{j}$. Refining further, find $\Omega^{3} \subset \Omega^{2}$ so that $\left|\bar{z}_{0}\right| \approx\left|\bar{z}_{2}\right| \approx R_{i}$ on $\Omega_{3}$.

Let

$$
\bar{z}_{1}=\left(\begin{array}{cc}
0 & -1 \\
1 & 0
\end{array}\right)\left(\begin{array}{cc}
A & \frac{B}{2} \\
\frac{B}{2} & C
\end{array}\right)\binom{\bar{u}_{0}}{\bar{v}_{0}} .
$$

Then, since $\left|\bar{z}_{0}\right| \approx\left|\bar{z}_{1}\right| \approx R_{i}$ and

$$
\left|\operatorname{det}\left(\bar{z}_{0}, \bar{z}_{1}\right)\right|=Q\left(\bar{z}_{0}\right) \gtrsim R_{1} R_{2}
$$

we have $|\sin (\rho)| \gtrsim \frac{R_{j}}{R_{i}}$ where $\rho$ is the angle between $\bar{z}_{0}$ and $\bar{z}_{1}$.
Let $\rho_{02}$ be the angle between $\bar{z}_{2}$ and $\bar{z}_{0}$ and let $\rho_{12}$ be the angle between $\bar{z}_{2}$ and $\bar{z}_{1}$. Then

$$
J_{z}=\left|\bar{z}_{0}\right|\left|\bar{z}_{1}\right|\left|\bar{z}_{2}\right|^{2}\left|\sin \left(\rho_{02}\right)\right|\left|\sin \left(\rho_{12}\right)\right| \approx R_{i}^{4}\left|\sin \left(\rho_{02}\right)\right|\left|\sin \left(\rho_{12}\right)\right| .
$$

For each $\bar{z}_{0}$, choose $D_{\bar{z}_{0}}$ so that $\min \left(\left|\sin \left(\rho_{02}\right)\right|,\left|\sin \left(\rho_{12}\right)\right|\right) \leq D_{\bar{z}_{0}}$ for exactly half of the $\bar{z}_{2}$. Note that $D_{\bar{z}_{0}} \gtrsim \frac{\beta}{R_{i}^{2}}$. If $D_{\bar{z}_{0}} \gtrsim \frac{R_{j}}{R_{i}}$ then, for the other half of the $\bar{z}_{2}$, we have

$$
\left|\sin \left(\rho_{02}\right)\right|\left|\sin \left(\rho_{12}\right)\right| \gtrsim \frac{R_{j}^{2}}{R_{i}^{2}}
$$

and so $J_{z} \gtrsim\left(R_{1} R_{2}\right)^{2} \geq R_{1} R_{2} \beta$ for half of the $\bar{z}_{2}$.
Since $|\sin (\rho)| \gtrsim \frac{R_{j}}{R_{i}}$, we have $\left|\sin \left(\rho_{12}\right)\right| \gtrsim \frac{R_{j}}{R_{i}}$ if $\left|\sin \left(\rho_{02}\right)\right| \ll \frac{R_{j}}{R_{i}}$ and we have $\left|\sin \left(\rho_{02}\right)\right| \gtrsim \frac{R_{j}}{R_{i}}$ if $\left|\sin \left(\rho_{12}\right)\right| \ll \frac{R_{j}}{R_{i}}$. Thus, if $D_{\bar{z}_{0}} \ll \frac{R_{j}}{R_{i}}$, we have

$$
\left|\sin \left(\rho_{02}\right)\right|\left|\sin \left(\rho_{12}\right)\right| \gtrsim \frac{R_{j}}{R_{i}} D_{\bar{z}_{0}} \gtrsim \frac{R_{j}}{R_{i}} \frac{\beta}{R_{i}^{2}}
$$

and thus

$$
J_{z} \gtrsim \beta R_{1} R_{2}
$$

for half of the $\bar{z}_{2}$.
In either case, we may find an $\left(\alpha^{\prime}, \beta^{\prime \prime}\right)$ tower $\Omega^{4} \subset \Omega^{3}$ with $\beta^{\prime \prime} \gtrsim \beta$ so that $J_{z} \gtrsim \beta R_{1} R_{2}$ on $\Omega^{4}$.

### 4.1.2. $d=8$

In this case, we assume that $\theta$ is of the form

$$
\theta(u, v)=\left(u, v, u^{2}, u v, v^{2}, u\left(u^{2}+v^{2}\right), v\left(u^{2}+v^{2}\right)\right) .
$$

We simplify ${ }^{1}$ the Jacobian (4.3) to

$$
\begin{aligned}
& \quad J_{z}=\left.\left|\operatorname{det}\left(\bar{z}_{2}, \bar{z}_{3}\right) \operatorname{det}\left(\bar{z}_{1}, \bar{z}_{2}\right)\right| \bar{z}_{2}\right|^{2} \mid \\
& \times\left|\operatorname{det}\left(\bar{z}_{3}, \bar{z}_{1}+\bar{z}_{2}\right)\right| \bar{z}_{2}+\left.\bar{z}_{3}\right|^{2}+\operatorname{det}\left(\bar{z}_{2}, \bar{z}_{3}\right)\left|\bar{z}_{1}+\bar{z}_{2}+\bar{z}_{3}\right|^{2}+\operatorname{det}\left(\bar{z}_{1}, \bar{z}_{2}+\bar{z}_{3}\right)\left|\bar{z}_{3}\right|^{2} \mid,
\end{aligned}
$$

where $\bar{z}_{j}:=z_{j-1}-z_{j}$ for $j=1,2,3$. Let $\rho_{i j}$ be the clockwise angle $\bar{z}_{i}$ to $\bar{z}_{j}$. After some algebra, we can rewrite

$$
\begin{aligned}
& J_{z}=\left|\bar{z}_{1}\right|^{2}\left|\bar{z}_{2}\right|^{5}\left|\bar{z}_{3}\right|^{2}\left|\sin \left(\rho_{23}\right) \sin \left(\rho_{12}\right)\right| \times \\
& \left|\sin \left(\rho_{12}\right)\right| \bar{z}_{3}\left|+\sin \left(\rho_{23}\right) \frac{\left|\bar{z}_{1}+\bar{z}_{2}+\bar{z}_{3}\right|^{2}-\left|\bar{z}_{2}+\bar{z}_{3}\right|^{2}}{\left|\bar{z}_{1}\right|}+\sin \left(\rho_{31}\right) \frac{\left|\bar{z}_{2}+\bar{z}_{3}\right|^{2}-\left|\bar{z}_{3}\right|^{2}}{\left|\bar{z}_{2}\right|}\right|
\end{aligned}
$$

Using that for any $i, j, k, \rho_{i j}+\rho_{j k}=\rho_{i k},\left\langle\bar{z}_{i}, \bar{z}_{j}\right\rangle=\left|z_{i}\right|\left|z_{j}\right| \cos \left(\rho_{i j}\right)$, and trigonometric identities we write

$$
\begin{aligned}
& J_{z}=\left|\bar{z}_{1}\right|^{2}\left|\bar{z}_{2}\right|^{5}\left|\bar{z}_{3}\right|^{2}\left|\sin \left(\rho_{23}\right) \sin \left(\rho_{12}\right)\right| \\
& \quad\left|\left|\bar{z}_{1}\right| \sin \left(\rho_{23}\right)+\left|\bar{z}_{2}\right| \sin \left(\rho_{23}+\rho_{21}\right)+\left|\bar{z}_{3}\right| \sin \left(\rho_{21}\right)\right| .
\end{aligned}
$$

To obtain the required lower bound for $J_{z}$, it suffices to use a localization to squares. Namely, in Lemma 2.1 and Lemma 4.1, we let $w_{1}, w_{2}$ be the coordinate axis directions and require that $R_{1}=R_{2}=R$. Note that using Lemma 4.1 as in Lemma 4.2, we can guarantee that we have an $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower $\Omega^{2} \subset \Omega^{1}$ with $\beta^{\prime} \gtrsim \beta$ so that

$$
\left|\bar{z}_{j}\right| \gtrsim R, \quad \text { and } \quad\left|\sin \left(\rho_{i j}\right)\right| \gtrsim \beta / R^{2}
$$

on $\Omega^{2}$. This implies that

$$
J_{z} \gtrsim R^{5} \beta^{2}| | \bar{z}_{1}\left|\sin \left(\rho_{23}\right)+\left|\bar{z}_{2}\right| \sin \left(\rho_{23}+\rho_{21}\right)+\left|\bar{z}_{3}\right| \sin \left(\rho_{21}\right)\right| .
$$

To estimate the remaining term we have to refine $\Omega^{2}$ once more. Note that for each fixed $\bar{z}_{1}, \bar{z}_{2}$ and a fixed argument for $\bar{z}_{3}$, we have

$$
\left|\left|\bar{z}_{1}\right| \sin \left(\rho_{23}\right)+\left|\bar{z}_{2}\right| \sin \left(\rho_{23}+\rho_{21}\right)+\left|\bar{z}_{3}\right| \sin \left(\rho_{21}\right)\right| \gtrsim(\beta / R)\left|\sin \left(\rho_{21}\right)\right| \gtrsim \beta^{2} / R^{3}
$$

for each value of $\left|\bar{z}_{3}\right|$ except for $\left|\bar{z}_{3}\right|$ in an interval of length $\ll(\beta / R)$. Therefore by removing a set of measure $\ll \beta$ for $\bar{z}_{3}$, we can find an $\left(\alpha^{\prime}, \beta^{\prime \prime}\right)$ tower $\Omega \subset \Omega^{2}$ with $\beta^{\prime \prime} \gtrsim \beta$ on which

$$
J_{z} \gtrsim R^{2} \beta^{4}=R_{1} R_{2} \beta^{4}
$$

[^1]
### 4.2. The case $3 n=d+2$

One may calculate that for $\omega=\left(z_{1}, \ldots, t_{n}, z_{n}\right)$ and $z_{i}=\left(u_{i}, v_{i}\right)$

$$
\Phi(\omega)=\left(z_{n}, y_{0}+\sum_{i=1}^{n} t_{i}\left(\theta\left(z_{i-1}\right)-\theta\left(z_{i}\right)\right)\right) .
$$

Thus,

$$
J=\left|\operatorname{det}\left(\partial \Phi / \partial u_{1}, v_{1}, \ldots, t_{n}, u_{n}, v_{n}\right)\right|=J_{t} \cdot J_{z}
$$

where

$$
J_{t}=\prod_{i=1}^{n-1}\left(t_{i+1}-t_{i}\right)^{2}, \quad \text { and }
$$

$$
\begin{gather*}
J_{z}=\mid \operatorname{det}\left(\theta_{u}\left(z_{1}\right), \theta_{v}\left(z_{1}\right), \ldots, \theta_{u}\left(z_{n-1}\right), \theta_{v}\left(z_{n-1}\right),\right.  \tag{4.5}\\
\left.\theta\left(z_{1}\right)-\theta\left(z_{2}\right), \ldots, \theta\left(z_{n-1}\right)-\theta\left(z_{n}\right)\right) \mid .
\end{gather*}
$$

On $\Omega^{1}$, we have $J_{t} \gtrsim \alpha^{2(n-1)}$. Thus, it remains to find an $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower $\Omega \subset \Omega^{1}$ with $J_{z} \gtrsim R_{1} R_{2} \beta^{l_{d}}$ on $\Pi$ and $\beta^{\prime} \gtrsim \beta$.
4.2.1. $d=7$

In this case, we assume that $\theta$ is of the form

$$
\theta(u, v)=\left(u, v, u^{2}, u v, v^{2}, P(u, v)\right),
$$

where $P(u, v)=a u^{3}+b u^{2} v+c u v^{2}+d v^{3}$. We simplify the Jacobian (4.5) to

$$
J_{z}=\left|\operatorname{det}\left(\bar{z}_{1}, \bar{z}_{2}\right)\right|^{2}\left|P\left(\bar{z}_{1}\right)\right|,
$$

where $\bar{z}_{j}:=z_{j+1}-z_{j}$. At this point we assume that $\left|P\left(\bar{z}_{1}\right)\right| \gtrsim\left|L\left(\bar{z}_{1}\right)\right|\left|\bar{z}_{1}\right|^{2}$, where $L\left(\bar{z}_{1}\right)=\left\langle\bar{z}_{1},(a, b)\right\rangle$ for some vector $(a, b)$. For example, with $\theta(u, v)=$ $\left(u, v, u^{2}, u v, v^{2}, u^{3}+v^{3}\right)$ we may take $(a, b)=(1,1)$.

We apply Lemma 3.2 and Lemma 4.1 with $w_{1}=(a, b)$ and $w_{2} \perp w_{1}$, and refine further as in the previous cases to obtain a $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower $\Omega$ such that $\beta^{\prime} \gtrsim \beta$, and

$$
\begin{aligned}
\left|\bar{z}_{1}\right| & \gtrsim \max \left(R_{1}, R_{2}\right), \\
\left|\operatorname{det}\left(\bar{z}_{1}, \bar{z}_{2}\right)\right| & \gtrsim \beta, \\
\left|L\left(\bar{z}_{1}\right)\right| & \gtrsim \min \left(R_{1}, R_{2}\right) .
\end{aligned}
$$

This implies that

$$
J_{z} \gtrsim \beta^{2} R_{1} R_{2} \max \left(R_{1}, R_{2}\right) \gtrsim \beta^{5 / 2} R_{1} R_{2}
$$

### 4.3. The case $3 n=d+3$

One may calculate that for $\omega=\left(z_{1}, t_{2}, \ldots, z_{n-1}, t_{n}\right)$ and $z_{i}=\left(u_{i}, v_{i}\right)$

$$
\Phi(\omega)=y_{0}+\sum_{i=1}^{n-1} t_{i}\left(\theta\left(z_{i-1}\right)-\theta\left(z_{i}\right)\right)+t_{n}\left(\theta\left(z_{n-1}\right)+e_{d}\right)
$$

Thus,

$$
J=\left|\operatorname{det}\left(\partial \Phi / \partial u_{1}, v_{1}, \ldots, u_{n-1}, v_{n-1}, t_{n}\right)\right|=J_{t} \cdot J_{z}
$$

where

$$
\begin{gathered}
J_{t}=\prod_{i=1}^{n-1}\left(t_{i+1}-t_{i}\right)^{2}, \quad \text { and } \\
J_{z}=\mid \operatorname{det}\left(\theta_{u}\left(z_{1}\right), \theta_{v}\left(z_{1}\right), \ldots, \theta_{u}\left(z_{n-1}\right), \theta_{v}\left(z_{n-1}\right)\right. \\
\left.\theta\left(z_{1}\right)-\theta\left(z_{2}\right), \ldots, \theta\left(z_{n-2}\right)-\theta\left(z_{n-1}\right)\right) \mid
\end{gathered}
$$

On $\Omega^{1}$, we have $J_{t} \gtrsim \alpha^{2(n-1)}$. Thus, it remains to find an $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower $\Omega \subset \Omega^{1}$ with $J_{z} \gtrsim R_{1} R_{2} \beta^{l_{d}}$ on $\Pi$ and $\beta^{\prime} \gtrsim \beta$.

### 4.3.1. $d=9$

In this case, we assume that $\theta$ is of the form

$$
\theta(u, v)=\left(u, v, u^{2}, u v, v^{2}, u^{3}+v^{3}, u^{2} v, u v^{2}\right)
$$

We simplify the Jacobian (4.6) to

$$
J_{z}=\left|\operatorname{det}\left(\bar{z}_{1}, \bar{z}_{2}\right)\right|^{4}\left|\bar{u}_{3} \bar{u}_{2} \bar{u}_{1}+\bar{v}_{3} \bar{v}_{2} \bar{v}_{1}\right|
$$

where $\bar{z}_{1}:=z_{2}-z_{1}, \bar{z}_{2}:=z_{3}-z_{1}$, and $\bar{z}_{3}:=z_{3}-z_{2}$.
We apply Lemma 3.2 and Lemma 4.1 with $w_{1}=(0,1)$ and $w_{2}=(1,-1)$, and refine further as in previous cases to obtain a $\left(\alpha^{\prime}, \beta^{\prime}\right)$ tower $\Omega^{2}$ such that $\beta^{\prime} \gtrsim \beta$, and

$$
\begin{align*}
\left|\bar{z}_{j}\right| & \sim \max \left(R_{1}, R_{2}\right)  \tag{4.7}\\
\left|\bar{u}_{j}\right| & \sim R_{2}  \tag{4.8}\\
\left|1+\bar{v}_{1} / \bar{u}_{1}\right| & \geq c_{1} R_{1} / R_{2}  \tag{4.9}\\
\left|\rho_{12}\right| & \gtrsim \beta / \max \left(R_{1}, R_{2}\right)^{2} \tag{4.10}
\end{align*}
$$

where $\rho_{i j} \in[-\pi / 2, \pi / 2]$ is the angle between $\bar{z}_{i}$ and $\bar{z}_{j}$.

Case 1: $R_{1} \gg R_{2}$. By (4.7) and (4.8), we have $\left|\bar{v}_{j}\right|>2\left|\bar{u}_{j}\right|$, which implies that

$$
\left|\bar{u}_{3} \bar{u}_{2} \bar{u}_{1}+\bar{v}_{3} \bar{v}_{2} \bar{v}_{1}\right| \gtrsim\left|\bar{v}_{3} \bar{v}_{2} \bar{v}_{1}\right| \gtrsim R_{1}^{3} .
$$

Also, by (4.7) and (4.10), we have $\left|\operatorname{det}\left(\bar{z}_{1}, \bar{z}_{2}\right)\right| \gtrsim \beta$. Therefore,

$$
J_{z} \gtrsim \beta^{4} R_{1}^{3} \gtrsim \beta^{9 / 2} R_{1} R_{2}
$$

Case 2: $R_{2} \gtrsim R_{1}$, and $\beta / R_{2}^{2} \lesssim\left|\rho_{12}\right| \leq c_{2} R_{1} / R_{2}$. Here $c_{2} \ll c_{1}$ is a fixed small constant.

Note that since $\left|\bar{z}_{j}\right| \sim R_{2}$ for each $j,\left|\rho_{12}\right| \leq c_{2} R_{1} / R_{2}$, and $\bar{z}_{2}=\bar{z}_{1}+\bar{z}_{3}$, by choosing $c_{2}$ sufficiently small, we have $\left|\rho_{13}\right| \leq c_{3} R_{1} / R_{2}$, where $c_{3} \ll c_{1}$.

We have two subcases $1+\bar{v}_{1} / \bar{u}_{1} \leq-c_{1} R_{1} / R_{2}$ and $1+\bar{v}_{1} / \bar{u}_{1} \geq c_{1} R_{1} / R_{2}$. In the former case, since $\left|\rho_{13}\right|,\left|\rho_{12}\right| \ll c_{1} R_{1} / R_{2}$, we have

$$
\bar{v}_{j} / \bar{u}_{j} \leq-1-c_{4} R_{1} / R_{2},
$$

for each $j$. Therefore,

$$
\begin{align*}
J(z) & \gtrsim \beta^{4} R_{2}^{3}\left|1+\frac{\bar{v}_{1}}{\bar{u}_{1}} \frac{\bar{v}_{2}}{\bar{u}_{2}} \frac{\bar{v}_{3}}{\bar{u}_{3}}\right|=\beta^{4} R_{2}^{3}\left(-\frac{\bar{v}_{1}}{\bar{u}_{1}} \frac{\bar{v}_{2}}{\bar{u}_{2}} \frac{\bar{v}_{3}}{\bar{u}_{3}}-1\right)  \tag{4.11}\\
& \geq \beta^{4} R_{2}^{3}\left(\left(1+c_{4} R_{1} / R_{2}\right)^{3}-1\right) \gtrsim \beta^{4} R_{2}^{3} R_{1} / R_{2} \gtrsim \beta^{9 / 2} R_{1} R_{2} .
\end{align*}
$$

In the latter case, we can additionally assume that $\bar{v}_{1} / \bar{u}_{1} \leq 1 / 4$ (Otherwise $\bar{v}_{j} / \bar{u}_{j} \gtrsim 1$ for each $j$ by the arguments above. This case can be handled as in case 1 ). As above, we now have (if $c_{2}$ is sufficiently small)

$$
1 / 2 \geq \bar{v}_{j} / \bar{u}_{j} \geq-1+c_{4} R_{1} / R_{2}
$$

for each $j$. As in (4.11), we have

$$
\begin{aligned}
J(z) & \gtrsim \beta^{4} R_{2}^{3}\left|1+\frac{\bar{v}_{1}}{\bar{u}_{1}} \frac{\bar{v}_{2}}{\bar{u}_{2}} \frac{\bar{v}_{3}}{\bar{u}_{3}}\right| \geq \beta^{4} R_{2}^{3}\left(1-\left|\frac{\bar{v}_{1}}{\bar{u}_{1}} \frac{\bar{v}_{2}}{\bar{u}_{2}} \frac{\bar{v}_{3}}{\bar{u}_{3}}\right|\right) \\
& \geq \beta^{4} R_{2}^{3}\left(1-\left|\frac{\bar{v}_{1}}{\bar{u}_{1}}\right|\right) \gtrsim \beta^{4} R_{2}^{3} R_{1} / R_{2} \gtrsim \beta^{9 / 2} R_{1} R_{2} .
\end{aligned}
$$

Case 3: $R_{2} \gtrsim R_{1}$, and $\left|\rho_{12}\right| \gtrsim R_{1} / R_{2}$. First note that

$$
\begin{equation*}
\left|\operatorname{det}\left(\bar{z}_{1}, \bar{z}_{2}\right)\right| \gtrsim R_{2}^{2} R_{1} / R_{2}=R_{1} R_{2} \tag{4.12}
\end{equation*}
$$

Now we estimate the remaining term in $J(z)$. With the previous notation $\bar{z}_{1}:=z_{2}-z_{1}, \bar{z}_{2}:=z_{3}-z_{1}$, and $\bar{z}_{3}:=z_{3}-z_{2}$, we have

$$
\begin{aligned}
\left|\bar{u}_{3} \bar{u}_{2} \bar{u}_{1}+\bar{v}_{3} \bar{v}_{2} \bar{v}_{1}\right| & =\left|u_{2}-u_{1}\right|\left|u_{3}^{2}-u_{3}\left(u_{2}+u_{1}\right)+g\left(z_{1}, z_{2}, v_{3}\right)\right| \\
& \sim R_{2}\left|u_{3}^{2}-u_{3}\left(u_{2}+u_{1}\right)+g\left(z_{1}, z_{2}, v_{3}\right)\right|=: R_{2}|\tilde{J}(z)| .
\end{aligned}
$$

By refining $\Omega^{2}$ once again, we have

$$
\begin{equation*}
\left|2 u_{3}-\left(u_{2}+u_{1}\right)\right| \gtrsim R_{2} . \tag{4.13}
\end{equation*}
$$

Note that $\tilde{J}$ is a quadratic polynomial in $u_{3}$ satisfying (by (4.13))

$$
\left|\tilde{J}_{u_{3}}\right| \gtrsim R_{2} .
$$

Therefore, for each fixed $z_{1}, z_{2}$, and $v_{3}$, by removing an interval of length $\sim \beta / R_{2}$ for $u_{3}$, we have

$$
|\tilde{J}| \gtrsim R_{2} \beta / R_{2}=\beta
$$

Combining the above estimates, we obtain

$$
J(z) \gtrsim\left(R_{1} R_{2}\right)^{4} R_{2} \beta \gtrsim \beta^{9 / 2} R_{1} R_{2}
$$

### 4.3.2. $d=6$

In this case the Jacobian turn out to be identically zero. To obtain $L^{p} \rightarrow L^{q}$ estimates we utilize the inflation argument from $[6,7]$. We only give a sketch of the argument. First, we replace the parameter space tower $\Pi$ (after the change of variables) with the following "parameter space tree":

$$
\begin{aligned}
& \bar{\Pi}=\left\{\left(z_{1}, t_{12}, z_{12}, t_{13}, z_{13}, t_{22}, z_{22}, t_{23}, z_{23}\right):\right. \\
& \left.\left(t_{1}, z_{1}, t_{12}, z_{12}, t_{13}, z_{13}\right),\left(t_{1}, z_{1}, t_{22}, z_{22}, t_{23}, z_{23}\right) \in \Omega\right\}
\end{aligned}
$$

which is a subset of $\mathbb{R}^{14}$ of measure $\gtrsim \alpha^{4} \beta^{5}$. We also define the inflated map $\varphi: \bar{\Pi} \rightarrow F \times F \subset \mathbb{R}^{14}$ as

$$
\varphi\left(z_{1}, t_{12}, \ldots, z_{23}\right)=\left(\Phi_{3}^{*}\left(t_{1}, z_{1}, t_{12}, z_{12}, t_{13}, z_{13}\right), \Phi_{3}^{*}\left(t_{1}, z_{1}, t_{22}, z_{22}, t_{23}, z_{23}\right)\right) .
$$

For the definition of $\Phi_{3}^{*}$, see Section 3.1. As before we need to find a lower bound for the Jacobian of $\varphi$ which is valid on a subset of $\bar{\Pi}$ of comparable measure. One can write the Jacobian $J$ as $J_{t} \cdot J_{z}$ where

$$
\begin{aligned}
& J_{t}=\left(t_{12}-t_{1}\right)\left(t_{22}-t_{1}\right)\left(t_{13}-t_{12}\right)^{2}\left(t_{23}-t_{22}\right)^{2} \\
& J_{z}=\operatorname{det}\left(z_{1}-z_{22}, z_{1}-z_{12}\right) \operatorname{det}\left(z_{1}-z_{12}, z_{13}-z_{12}\right)^{2} \operatorname{det}\left(z_{1}-z_{22}, z_{23}-z_{22}\right)^{2}
\end{aligned}
$$

We can obtain the following lower bounds for $J_{t}$ and $J_{z}$ on a subset of $\bar{\pi}$ of measure $\gtrsim \alpha^{4} \beta^{5}$ by considerations as above:

$$
\left|J_{t}\right| \gtrsim \alpha^{6}, \quad\left|J_{z}\right| \gtrsim \beta^{5} .
$$

This implies that

$$
|F|=\sqrt{|F \times F|} \gtrsim \sqrt{\alpha^{4} \beta^{5} \alpha^{6} \beta^{5}}=\alpha^{5} \beta^{5} .
$$

Using the definition of $\alpha$ and $\beta$, we obtain all $L^{p} \rightarrow L^{q}$ estimates for $(1 / p, 1 / q)$ in the interior of the convex hull of the points $(1 / 2,2 / 5),(0,1)$, $(1,0),(1,1)$, which is essentially optimal.

## A. Multi-linear estimates

In this appendix, we present an extension of the method in [5] to the multilinear setting. We only discuss various model cases.

## A.1. Restricted directions

Let $\theta$ be the moment curve $\theta(u)=\left(u, u^{2}, \ldots, u^{d-1}\right)$. Suppose $I_{1}$ and $I_{2}$ are disjoint compact intervals, and $g_{j}$ is a function on $I_{j} \times \mathbb{R}^{d-1}, j=1,2$.

We can consider the (adjoint) bilinear $X$-ray estimate

$$
\left\|T^{*}\left[g_{1}\right] T^{*}\left[g_{2}\right]\right\|_{L^{\frac{p^{\prime}}{2}}} \lesssim\left\|g_{1}\right\|_{L^{q^{\prime}}}\left\|g_{2}\right\|_{L^{q^{\prime}}}
$$

From the $\delta$-ball counterexample, we have the usual necessary condition

$$
\begin{equation*}
\frac{d-1}{q^{\prime}} \leq \frac{d}{p^{\prime}} \tag{A.1}
\end{equation*}
$$

Given a set of points $E \subset B(0,1) \subset \mathbb{R}^{d}$ and sets of lines $F_{1} \subset I_{1} \times \mathbb{R}^{d-1}$ and $F_{2} \subset I_{2} \times \mathbb{R}^{d-1}$ consider the quantity

$$
\left\langle F_{1}, F_{2}, E\right\rangle_{T}:=\int_{\mathbb{R}^{d}} T^{*}\left[\chi_{F_{1}}\right](x) T^{*}\left[\chi_{F_{2}}\right](x) \chi_{E}(x) d x
$$

Our aim is to obtain restricted weak type inequalities,

$$
\left\langle F_{1}, F_{2}, E\right\rangle_{T} \lesssim|E|^{1-2 / p \prime}\left|F_{1}\right|^{1 / q \prime}\left|F_{2}\right|^{1 / q \prime}
$$

After pigeonholing and losing a $\log ^{2}$, we can assume that $T^{*}\left[\chi_{F_{1}}\right] \approx \beta_{1}$ on $E$ and $T^{*}\left[\chi_{F_{2}}\right] \approx \beta_{2}$ on $E$ (this slightly changes $\left(p^{\prime}, q^{\prime}\right)$ that we obtain at the end). Define

$$
\alpha_{1}:=\frac{\left\langle F_{1}, F_{2}, E\right\rangle_{T}}{\beta_{2}\left|F_{1}\right|} \approx \frac{\int_{\mathbb{R}^{d}} \chi_{F_{1}}(x) T\left(\chi_{E}\right)(x) d x}{\left|F_{1}\right|}
$$

and

$$
\alpha_{2}:=\frac{\left\langle F_{1}, F_{2}, E\right\rangle_{T}}{\beta_{1}\left|F_{2}\right|} \approx \frac{\int_{\mathbb{R}^{d}} \chi_{F_{2}}(x) T\left(\chi_{E}\right)(x) d x}{\left|F_{2}\right|} .
$$

Note that

$$
\beta_{1} \beta_{2} \approx \frac{\left\langle F_{1}, F_{2}, E\right\rangle_{T}}{|E|}
$$

and, on average, $T \chi_{E} \approx \alpha_{j}$ on $F_{j}$.

We restrict ourself to the case when $d=2 D$ is even. Define

$$
\begin{aligned}
\phi_{1}\left(u_{1}\right)= & \left(u_{1}, x_{0}-t_{0} \theta\left(u_{1}\right)\right), \\
\phi_{2}\left(u_{1}, t_{1}\right)= & x_{0}-t_{0} \theta\left(u_{1}\right)+t_{1}\left(\theta\left(u_{1}\right)+e_{d}\right), \\
& \vdots \\
\phi_{d-1}\left(u_{1}, t_{1}, \ldots, t_{D-1}, u_{D}\right)= & \left(u_{D}, x_{0}-t_{0} \theta\left(u_{1}\right)+\sum_{j=1}^{D-1} t_{j}\left[\theta\left(u_{j}\right)-\theta\left(u_{j+1}\right)\right]\right), \\
\phi_{d}\left(u_{1}, t_{1}, \ldots, u_{D}, t_{D}\right)= & x_{0}-t_{0} \theta\left(u_{1}\right)+\sum_{j=1}^{D-1} t_{j}\left[\theta\left(u_{j}\right)-\theta\left(u_{j+1}\right)\right] \\
& +t_{D}\left(\theta\left(u_{D}\right)+e_{d}\right) .
\end{aligned}
$$

We can set up a parameter space tower $\Omega$ with $|\Omega|=\left(\beta_{1} \alpha_{1}\right)^{D-\lfloor D / 2\rfloor}\left(\beta_{2} \alpha_{2}\right)^{\lfloor D / 2\rfloor}$ so that

$$
\begin{aligned}
\phi_{j} \rightarrow F_{1}, & \text { if } j=1(\bmod 4), \\
\phi_{j} \rightarrow F_{2}, & \text { if } j=3(\bmod 4), \\
\phi_{j} \rightarrow E, & \text { if } j \text { is even. }
\end{aligned}
$$

Then the Jacobian of $\phi_{d},[9]$, is

$$
|J|=c_{d} \prod_{j=1}^{D}\left|t_{j}-t_{j-1}\right| \prod_{1 \leq j<k \leq D}\left|u_{j}-u_{k}\right|^{4}
$$

Let $p(j):=1$ if $j$ is odd, and $p(j):=2$ if $j$ is even. By the transversality $\left|u_{j}-u_{k}\right| \gtrsim 1$ if $p(j) \neq p(k)$. By refining $\Omega$, we can assume that $\left|u_{j}-u_{k}\right| \gtrsim$ $\beta_{p(k)}$ if $p(j)=p(k)$, and $\left|t_{j}-t_{j-1}\right| \gtrsim \alpha_{p(j)}$. Thus

$$
|E| \gtrsim|\Omega| \alpha_{1}^{D-\lfloor D / 2\rfloor} \alpha_{2}^{\lfloor D / 2\rfloor} \prod_{1 \leq j<k \leq D, p(j)=p(k)} \beta_{p(k)}^{4}
$$

We can symmetrize this by switching the roles of $\alpha_{1}, \beta_{1}$ and $\alpha_{2}, \beta_{2}$ and obtain

$$
|E| \gtrsim\left(\alpha_{1} \alpha_{2}\right)^{D}\left(\beta_{1} \beta_{2}\right)^{D / 2} \prod_{1 \leq j<k \leq D, p(j)=p(k)}\left(\beta_{1} \beta_{2}\right)^{2}
$$

This gives us

$$
\begin{aligned}
& |E| \gtrsim\left(\alpha_{1} \alpha_{2}\right)^{D}\left(\beta_{1} \beta_{2}\right)^{D(D-1) / 2}, \quad \text { if } D \text { is even, } \\
& |E| \gtrsim\left(\alpha_{1} \alpha_{2}\right)^{D}\left(\beta_{1} \beta_{2}\right)^{\left(D^{2}-D+1\right) / 2}, \quad \text { if } D \text { is odd. }
\end{aligned}
$$

Plugging in the notation, we have

$$
\begin{aligned}
& \left\langle F_{1}, F_{2}, E\right\rangle_{T} \lesssim|E|^{\frac{D^{2}-3 D+2}{D^{2}+D}}\left(\left|F_{1}\right| F_{2} \mid\right)^{\frac{2}{D+1}}, \quad \text { if } D \text { is even, } \\
& \left\langle F_{1}, F_{2}, E\right\rangle_{T} \lesssim|E|^{\frac{D^{2}-3 D+3}{D^{2}+D+1}}\left(\left|F_{1}\right| F_{2} \mid\right)^{\frac{2 D}{D^{2}+D+1}}, \quad \text { if } D \text { is odd. }
\end{aligned}
$$

This corresponds to $p^{\prime}=\frac{D+1}{2} \frac{d}{d-1}, q^{\prime}=\frac{D+1}{2}$ for even $D$, and $p^{\prime}=\frac{D^{2}+D+1}{d-1}, q^{\prime}=$ $\frac{D^{2}+D+1}{d}$ for odd $D$.

## A.2. Unrestricted directions

For $z \in \mathbb{R}^{d-1}$, we have the unrestricted $X$-ray transform $T=T^{\theta}$ where $\theta(z)=z$. Perhaps the estimates of most interest are the $d$-linear estimates

$$
\left\|\prod_{j=1}^{d} T^{*}\left[g_{j}\right]\right\|_{L^{\frac{p^{\prime}}{d}}} \lesssim \prod_{j=1}^{d}\left\|g_{j}\right\|_{L^{q^{\prime}}}
$$

where, say, each $g_{j}$ is supported on $B\left(\xi_{j}, \frac{1}{100}\right)$, and where $\xi_{j}=e_{j}$ for $j=$ $1, \ldots, d-1$ and $\xi_{d}=0$, see [1]. We give a sketch of the method when $d=3$ for the weaker inequality

$$
\begin{equation*}
\left|\left\{x: T^{*}\left[\chi_{F_{j}}\right] \geq \beta_{j}, j=1, \ldots, d\right\}\right| \lesssim\left(\prod_{j=1}^{d} \frac{\left|F_{j}\right|^{1 / q^{\prime}}}{\beta_{j}}\right)^{p^{\prime} / d} \tag{A.2}
\end{equation*}
$$

which follows from

$$
\int \prod_{j=1}^{d} T^{*}\left[\chi_{F_{j}}\right](x) \chi_{E}(x) d x \lesssim|E|^{1-d / p^{\prime}} \prod_{j=1}^{d}\left|F_{j}\right|^{1 / q^{\prime}}
$$

where $E=\left\{x: T^{*}\left[\chi_{F_{j}}\right] \approx \beta_{j}, j=1, \ldots, d\right\}$.
Consider the inflated map

$$
\begin{aligned}
& \phi\left(z_{1}, t_{1,1}, z_{1,1}, t_{2,1}, z_{2,1}\right) \\
& \quad=\left(\left(z_{1,1}, x_{0}+\left(t_{1,1}-t_{0}\right) z_{1}-t_{1,1} z_{1,1}\right),\left(z_{2,1}, x_{0}+\left(t_{2,1}-t_{0}\right) z_{1}-t_{2,1} z_{2,1}\right)\right)
\end{aligned}
$$

which has Jacobian

$$
|J|=\left|\left(t_{1,1}-t_{0}\right)\left(t_{2,1}-t_{0}\right) \operatorname{det}\left(z_{1,1}-z_{1}, z_{2,1}-z_{1}\right)\right| .
$$

We can construct a "Parameter space tree" $\Omega=\left\{\left(z_{1}, t_{1,1}, z_{1,1}, t_{2,1}, z_{2,1}\right)\right\}$ of measure $\alpha_{1}^{2} \beta_{1} \beta_{2} \beta_{3}$ so that $z_{1} \in B\left(\xi_{1}, \frac{1}{100}\right), z_{1,1} \in B\left(\xi_{2}, \frac{1}{100}\right)$, and $z_{3} \in$ $B\left(\xi_{3}, \frac{1}{100}\right)$, and

$$
\phi(\Omega) \subset F_{2} \times F_{3} .
$$

Above,

$$
\alpha_{1}=\frac{\int T^{*}\left[\chi_{F_{1}}\right] T^{*}\left[\chi_{F_{2}}\right] T^{*}\left[\chi_{F_{3}}\right] \chi_{E}}{\beta_{2} \beta_{3}\left|F_{1}\right|}, \text { etc.. }
$$

By our "trilinear" hypotheses on $z_{1}, z_{1,1}$, and $z_{2,1}$, we have $\mid \operatorname{det}\left(z_{1,1}-\right.$ $\left.z_{1}, z_{2,1}-z_{1}\right) \mid \gtrsim 1$ on $\Omega$. Thus

$$
\left|F_{2}\right|\left|F_{3}\right| \gtrsim \beta_{1} \beta_{2} \beta_{3} \alpha_{1}^{4}
$$

Combined with the permuted estimates, we have

$$
\left(\left|F_{1}\right|\left|F_{2} \| F_{3}\right|\right)^{2} \gtrsim\left(\beta_{1} \beta_{2} \beta_{3}\right)^{3}\left(\alpha_{1} \alpha_{2} \alpha_{3}\right)^{4}
$$

This gives (A.2) for $d=3$ with $p=\frac{7}{3}, q=7$. These exponents are weaker than those implied by [19], but nonetheless illustrate that the method of [9] may yield estimates with unrestricted directions beyond those of [12] and [3].

## A.3. The Loomis-Whitney inequality

For $j=1, \ldots, d$, let $\pi_{j}: \mathbb{R}^{d} \rightarrow \mathbb{R}^{d-1}$ be the map $\pi_{j}\left(x_{1}, \ldots, x_{d}\right)=\left(x_{1}, \ldots, x_{j-1}\right.$, $x_{j+1}, \ldots x_{d}$ ). The Loomis-Whitney inequality [16] states that

$$
\int_{\mathbb{R}^{d}} \prod_{j=1}^{d} f_{j}\left(\pi_{j}(x)\right) d x \leq \prod_{j=1}^{d}\left\|f_{j}\right\|_{L^{d-1}}
$$

for functions $f_{1}, \ldots, f_{d}$ on $\mathbb{R}^{d-1}$.
Below, we give (except for a constant factor) a "multilinear $T^{*} T$ " proof for the case $f_{j}=\chi_{E_{j}}$.

Suppose $E_{1}, \ldots, E_{d} \subset \mathbb{R}^{d-1}$ with each $\left|E_{i}\right|<\infty$ and let

$$
\left\langle E_{1}, \ldots, E_{d}\right\rangle=\int_{\mathbb{R}^{d}} \prod_{j} \chi_{E_{j}}\left(\pi_{j}(x)\right) d x
$$

Define

$$
\alpha_{j}=\frac{\left\langle E_{1}, \ldots, E_{d}\right\rangle}{\left|E_{j}\right|},
$$

and given $y \in \mathbb{R}^{d-1}$ and a function $g$ on $\mathbb{R}^{d}$ let

$$
T^{i}[g](y)=\int_{\mathbb{R}} g\left(y+t e_{i}\right) d t
$$

so that

$$
\int_{\mathbb{R}^{d}} \prod_{j} f_{j}\left(\pi_{j}(x)\right) d x=\int_{\mathbb{R}^{d-1}} f_{i}(y) T^{i}\left[\prod_{j \neq i} f_{j}\left(\pi_{j}(\cdot)\right)\right](y) d y .
$$

For $i=1, \ldots, d$ let

$$
E_{i}^{\prime}=\left\{y \in E_{i}: T^{i}\left[\prod_{j<i} \chi_{E_{j}^{\prime}\left(\pi_{j}(\cdot)\right)} \prod_{j>i} \chi_{E_{j}}\left(\pi_{j}(\cdot)\right)\right] \geq \frac{\alpha_{i}}{2^{i}}\right\}
$$

and, by induction on $i$, note that

$$
\left\langle E_{1}^{\prime}, \ldots, E_{i}^{\prime}, E_{i+1}, \ldots, E_{d}\right\rangle \geq \frac{\left\langle E_{1}, \ldots, E_{d}\right\rangle}{2^{i}}
$$

We may then find a parameter space tower $\Omega=\left\{t_{d}, \ldots, t_{1}\right\} \subset \mathbb{R}^{d}$ and $y \in E_{d}^{\prime}$ so that $|\Omega| \geq 2^{-\frac{d(d+1)}{2}} \prod_{j=1}^{d} \alpha_{i}$ and so that

$$
\pi_{i}\left(y+\sum_{j=1}^{d} t_{j} e_{j}\right) \in E_{i}
$$

for every $i$ and $\left(t_{1}, \ldots, t_{d}\right) \in \Omega$. Thus

$$
\left\langle E_{1}, \ldots, E_{d}\right\rangle \geq 2^{-\frac{d(d+1)}{2}} \prod_{j=1}^{d} \alpha_{j}
$$

or in other words

$$
\left\langle E_{1}, \ldots, E_{d}\right\rangle \leq 2^{-\frac{d(d+1)}{2}} \prod_{j=1}^{d}\left|E_{j}\right|^{\frac{1}{d-1}}
$$
