# CERTAIN TYPES OF GROUPS OF AUTOMORPHISMS <br> OF A FACTOR 

Noboru Suzuki

(Received April 6, 1959)

In studying the crossed products of rings of operators, we have shown in [4] that an arbitrary countable group admits a faithful representation as a group of outer automorphisms of an approximately finite factor on a separable Hilbert space (the so-called outer automorphic representation). The object of the present paper is to discuss the algebraic properties of groups of outer automorphisms of the approximately finite factor, which are the outer automorphic representations of certain torsion free groups.

An automorphism (a group of automorphisms) of a factor is said to be ergodic if it leaves only the center elementwise invariant. Our first task is to ask whether there exists an ergodic group of automorphisms of the approximately finite factor. Indeed, we shall find the necessary and sufficient condition that the outer automorphic representation of a group be ergodic. The second one is to examine the outer automorphic representation of a free product of two arbitrary torsion free countable groups and show that the crossed products of the approximately finite factor by such groups of automorphisms are not approximately finite.

1. In the starting point, we shall recall the construction in [4] of the outer automorphic representation of a countably infinite group $G$. Let $\Delta$ be a set of all functions $\boldsymbol{\alpha}$ on $G$ taking only the values 0,1 such that $\boldsymbol{\alpha}(g)=0$ except for a finite number of $g$ 's. Then $\Delta$ is an additive group with the addition $[\alpha+\beta](g)=\alpha(g)+\beta(g)(\bmod 2)$. Further, define $\Delta^{\prime}$ as a set of all functions $\varphi$ on $\Delta$ taking only the values 0,1 such that $\varphi(\gamma)=0$ except for a finite number of $\gamma^{\prime}$ s, and make $\Delta^{\prime}$ into a group by the addition $[\varphi+$ $\psi](\gamma)=\phi(\gamma)+\psi(\gamma)(\bmod 2)$. Now we make the pair $\mathcal{G}=\left(\Delta^{\prime}, \Delta\right)$ into a group by defining

$$
(\boldsymbol{\varphi}, \alpha)(\psi, \beta)=\left(\boldsymbol{\varphi}^{\beta}+\psi, \alpha+\beta\right)
$$

where $\varphi, \psi \in \Delta^{\prime}, \alpha, \beta \in \Delta$ and $\boldsymbol{\phi}^{\beta}(\gamma)=\phi(\gamma+\beta)$. Let $\left\{V_{(\varphi, \alpha)}\right\}_{(\varphi, \alpha) \in f}$ be unitary operators on $l_{2}(\mathcal{G})$ defined by $\left[V_{(\varphi, \alpha)} f\right]((\boldsymbol{\psi}, \beta))=f((\boldsymbol{\psi}, \beta)(\boldsymbol{\phi}, \boldsymbol{\alpha}))$ for all $f \in$ $l_{2}(\mathcal{G})$, then a factor $\mathbf{M}$ generated by $\left\{V_{(\varphi, \alpha)}\right\}_{(\varphi, \alpha) \in \mathcal{G}}$ is an approximately finite factor on a separadle Hilbert space. Hereupon, for each $g \in G$, define an automorphism $T_{g}$ on $\Delta$ by

$$
\left[T_{g} \alpha\right]\left(g^{\prime}\right)=\alpha\left(g g^{\prime}\right) \text { for all } g^{\prime} \in G
$$

and successively an automorphism $T_{g}^{\prime}$ on $\Delta^{\prime}$ by

$$
\left[T_{g}^{\prime} \varphi\right](\gamma)=\varphi\left(T_{g-1} \gamma\right) \text { for all } \gamma \in \Delta .
$$

Then the mappings $V_{(\varphi, \alpha)} \rightarrow V^{\theta_{g}}=V_{\left(T_{g}^{\prime} T_{g} \alpha\right)}$ give a group of outer automorphisms of $\mathbf{M}$ and the mapping $g \rightarrow \theta_{g}$ gives the outer automorphic representation of $G$.

Following the previous paper [4], we shall state the necessary and sufficient condition that the outer automorphic representation of a group be ergodic.

THEOREM 1. Let $G$ be a countably infinite group with the unit $e$, then for each element $g \neq e$ in $G$, the corresponding outer automorphism $\theta_{g}$ is ergodic if and only if the order of $g$ is infinite

The proof is given successively by means of the following lemmas.
LEMMA 1. If $g$ is an element of finite order in $G$, then there exists $(\varphi, \alpha) \in \mathcal{G}$ such that $(\varphi, \alpha)=\left(T_{g}^{\prime} \varphi, T_{g} \alpha\right)$.

PROOF. Let us select an element $\alpha \in \Delta$ as follows : $\boldsymbol{\alpha}\left(g^{\prime}\right)=1$ on a finite set $F=\left\{e, g, g^{2}, \ldots \ldots, g^{n-1}(n\right.$ : the order of $\left.g)\right\}$ and $=0$ elsewhere, and choose an element $\phi \in \Delta^{\prime}$ such that $\varphi(\gamma)=1$ on an $\alpha \in \Delta$ and $=0$ elsewhere Then it is easily verified that $(\boldsymbol{\varphi}, \boldsymbol{\alpha})=\left(T_{g}^{\prime} \boldsymbol{\varphi}, T_{g} \boldsymbol{\alpha}\right)$, in fact, $\left[T_{g} \alpha\right]\left(g^{\prime}\right)=1$ on $F$ and $=0$ elsewhere, i. e. $T_{g} \alpha=\alpha$, and also $\left[T_{g}^{\prime} \boldsymbol{\varphi}\right](\gamma)=1$ if $\gamma=T_{g} \alpha=\alpha$ and $=0$ elsewhere, i. e. $T_{g}^{\prime} \boldsymbol{\varphi}=\boldsymbol{\varphi}$.

LEMMA 2 If $g$ is an element of infinite order of $G$, then for any finite subset $F$ of $G, F g \neq F(g F \neq F)$.

In fact, if $F g=F$, for a fixed element $h \in F$, all of $h g^{n}(n=0,1,2, \ldots)$ are distinct and belong to $F$ and so it contradicts to the finiteness of $F$.

LEMMA 3. If $g$ is an element of infinite order of $G$, then $(\varphi, \alpha) \neq$ ( $\left.T_{\imath}^{\prime} \boldsymbol{\varphi}, T_{\imath} \boldsymbol{\alpha}\right)$ for all $(\boldsymbol{\phi}, \boldsymbol{\alpha}) \neq(0,0) \in \mathcal{G}$.

PROOF. Let $(\boldsymbol{\varphi}, \alpha) \neq(0,0)$ be an element of $\mathscr{G}$. If $\alpha \neq 0$, i. e. $\alpha\left(g^{\prime}\right)=1$ on a finite subset $F$ of $G$ and $=0$ elsewhere, then $\left[T_{\rho} \alpha\right]\left(g^{\prime}\right)=1$ on a finite subset $g^{-1} F$ and $=0$ elsewhere. However, since $F \neq g^{-1} F$ by Lemma 2, $T_{g} \alpha$ $\neq \alpha$. If $\alpha=0$, then $\varphi$ may be taken as an element of $\Delta^{\prime}$ such that $\varphi(\gamma)$ $=1$ on a finite subset $\Delta_{0}$ of $\Delta$ and $=0$ elsewhere. Putting $G_{0}=\bigcup_{\gamma \in \Delta_{0}}\left\{g^{\prime}: \gamma\left(g^{\prime}\right)\right.$ $=1\}, G_{0}$ is a finite subset of $G$ and each element $\alpha \in \Delta_{0}$ vanishes on $G$ $-G_{0}$. But, since $G_{0} \neq g^{-1} G_{0}$ by Lemma 2, there must be an element $\beta \in$ $T_{g} \Delta_{0}$ which does not vanish on $G-G_{0}$, and so $\Delta_{0} \neq T_{g} \Delta_{0}$, or $T_{g}^{\prime} \boldsymbol{\varphi} \neq \varphi$.

Therefore, for each $(\boldsymbol{\varphi}, \boldsymbol{\alpha}) \neq(0,0) \in \mathcal{G},(\boldsymbol{\rho}, \boldsymbol{\alpha}) \neq\left(T_{\imath}^{\prime} \boldsymbol{\varphi}, T_{\vartheta} \boldsymbol{\alpha}\right)$.
PROOF OF THE THEOREM. The necessity have been already proved by Lemma 1, and so it remains only to show the sufficiency. Let $A$ be an element in $\mathbf{M}$ fixed under $\theta_{g}$, then $A=A^{\theta_{g^{n}}}$ for all $n=1,2, \cdots \cdots$. According to Lemma 5.3.6 in [1], $A$ is expressed in the form:

$$
\sum_{(p, \alpha) \in \mathcal{G}} \lambda_{(\varphi, \alpha)} V_{(\varphi, \alpha)} .
$$

where $\Sigma$ is taken in the sense of metric convergence in $\mathbf{M}$ and a family $\left\{\lambda_{(\varphi, a)}\right\}$ of scalars is unique. Thus we have

$$
\sum_{(\varphi, \alpha) \in \mathcal{G}} \lambda_{(\varphi, \alpha)} V_{(\varphi, \alpha)}=\sum_{(\varphi, \alpha) g} \lambda_{(\varphi, \alpha)} V_{\left(r_{g, m^{\prime} \varphi}^{\prime}, T_{g^{n}} \alpha\right)}
$$

for all $n$. Now suppose that $\lambda_{(\varphi \alpha)} \neq 0$ for some $(\varphi, \alpha) \neq(0,0)$, then since a sequence ( $T_{y^{\prime}}^{\prime-1} \varphi, T_{g^{n}}^{-1} \alpha$ ) consists of distinct elements of $\mathscr{\rho}$ from Lemma 3, by the uniqueness of the family $\left\{\lambda_{(\varphi, \alpha)}\right\}$ we obtain

$$
\lambda_{(\varphi, \alpha)}=\lambda_{\left(r_{g}^{\prime}-1 \varphi, T_{g}^{-1} \alpha\right)}=\lambda_{\left(r_{g}^{\prime}-\overline{2}_{\varphi} \varphi_{,}, r_{g}^{-1} \alpha\right)}=\cdots \cdots,
$$

which contradicts $\sum_{(\varphi, \alpha): g}\left|\boldsymbol{\lambda}_{(\varphi, \alpha)}\right|^{2}<\infty$. Therefore $A$ is a scalar multiple of the identity.
2. Let $G_{i}$ be two torsion free countable groups ( $i=1,2$ ) and let $G=$ $G_{1} * G_{2}$ be the free product of $G_{i}$. From the preceding theorem we see that the outer automorphic representation of $G$ is ergodic and in particular it consists of ergodic automorphisms of $\mathbf{M}$ except the unit. Furthermore we shall show that it possesses the distinguished algebraic property relative to the norm $[[]]$ defined by the canonical trace $\operatorname{Tr}$ (Recall that for $A \in \mathbf{M}$, $\left.[[A]]=\operatorname{Tr}\left(A^{*} A\right)^{\frac{1}{2}}\right)$.

Lemma 4. The outer automorphic representation of the group $G$ with the unit $e$ has the following property: There exists $g \neq e$ in $G$ such that, for all $A \in M$ with $\operatorname{Tr}(A)=0$,

$$
k[[A]] \leqq\left[\left[A-A^{\theta_{q}}\right]\right] \leqq 2[[A]]
$$

where $k$ is a positive constant and does not depend on $A$.
PROOF. By the expression in [1: Lemma 5.3.6] used in the above section, an element $A$ with $\operatorname{Tr}(A)=0$ is expressed in the following form :

$$
\sum_{\substack{\varphi(\alpha, \alpha) \in \in \\(\varphi, \alpha)(0,0)}} \lambda_{(\varphi, \alpha)} V_{(\varphi, \alpha)}
$$

and hence $\left[\left[A-A^{\theta g-1}\right]\right]=\left(\sum_{\substack{\varphi, \alpha) \in \mathscr{E} \\(\varphi, \alpha) \neq(0,0)}}\left|\lambda_{(\varphi, \alpha)}-\lambda_{\left(T_{g}^{\prime} \varphi, T_{g} \alpha\right)}\right|^{2}\right)^{\frac{1}{2}}$
for all $g$ in $G$. Define the equivalence relation on $\mathscr{G}-(0,0)$ as follows: $(\boldsymbol{\mathcal { O }}, \boldsymbol{\alpha})$ $\equiv(\psi, \beta)(\bmod G)$ if and only if there exists $g \in G$ such that $\left(T_{\imath}^{\prime} \boldsymbol{\varphi}, T_{\imath} \alpha\right)=$
$(\psi, \beta)$, and decompose $\mathscr{G}$ into equivalent classes $\left\{\mathscr{G}_{i}\right\}$. Then the elements of $\mathcal{G}_{i}$ can be written as ( $T_{g}^{\prime} \boldsymbol{\varphi}, T_{g} \boldsymbol{\alpha}$ ) where ( $\boldsymbol{\varphi}, \boldsymbol{\alpha}$ ) is a fixed element in $\mathcal{Y}_{i}$ and $g$ runs over $G$, and as all elements ( $T_{g}^{\prime} \boldsymbol{\rho}, T_{g} \alpha$ ) are distinct by Theorem 1, their expressions are unique. Thus, putting $s_{i}=\left(\sum_{(\varphi, \beta) \in \mathcal{F}_{i}}\left|\lambda_{(\psi, \beta)}\right|^{2}\right)^{\frac{1}{2}}$ and $\nu_{i}(E)$ $=\sum_{n \in E}\left|\lambda_{\left(T_{h}^{\prime}, \tau_{h} \alpha\right)}\right|^{2}$ for any su' set $E$ of $G$, then

$$
s_{i}=\nu_{i}(G)^{\frac{1}{2}}
$$

Pick up $g_{1} \neq e_{1}$ in $G_{1}$ and $g_{2}, g_{3} \neq e_{2}$ in $G_{2}\left(e_{1}, e_{2}\right.$ being the unit of $G_{1}, G_{2}$ respectively) and put $P_{i j}=\left\{\sum_{(\mu, \beta) \in q_{1}}\left|\lambda_{(\psi, \beta)}-\dot{\lambda}_{\left(r_{g}^{\prime}, \psi_{,} r_{g}, \beta\right)}\right|^{2}\right\}^{\frac{1}{2}}(j=1,2,3)$, then

$$
P_{i j}=\left\{\sum_{h e G}\left|\lambda_{\left(T_{h} h^{\prime}, T_{h} \alpha\right)}-\lambda_{\left(T_{h g}, \rho_{j}, T_{h g}, \alpha\right)}\right|^{2}\right\}^{\frac{1}{2}}
$$

and

$$
\begin{equation*}
\left|\nu_{i}(E)^{\frac{1}{2}}-\nu_{i}\left(E g_{j}\right)^{\frac{1}{2}}\right| \leqq P_{i j}(j=1,2,3) \tag{1}
\end{equation*}
$$

for any subset $E$ of $G$. Now we define $E_{1}$ as the set of $h$ 's, $h \neq e$ having the normal form $h_{1} h_{2} \ldots \ldots h_{p}$ in which $h_{p}$ belongs to $G_{1}$ and $E_{2}=G-E_{1}$. Then, by the inequality (1),

$$
\begin{aligned}
& \left|\boldsymbol{\nu}_{i}\left(E_{1}\right)^{\frac{1}{2}}-\boldsymbol{\nu}_{i}\left(E_{1} g_{2}\right)^{\frac{1}{2}}\right| \leqq P_{i 2} \\
& \left|\boldsymbol{\nu}_{i}\left(E_{1} g_{2}\right)^{\frac{1}{2}}-\boldsymbol{\nu}_{i}\left(E_{1} g_{2} g_{1}\right)^{\frac{1}{2}}\right| \leqq P_{i 1}
\end{aligned}
$$

and hence we have

$$
\begin{equation*}
\left|\nu_{i}\left(E_{1}\right)^{\frac{1}{2}}-\nu_{i}\left(E_{1} g_{2} g_{1}\right)^{\frac{1}{2}}\right| \leqq P_{i 1}+P_{i 2} \tag{2}
\end{equation*}
$$

Since $E_{1} g_{2} g_{1} \subsetneq E_{1}, E_{1}-E_{1} g_{2} g_{1} \neq \phi$, and (2) gives

$$
\begin{align*}
& \nu_{i}\left(E_{1}-E_{1} g_{2} g_{1}\right)=\nu_{i}\left(E_{1}\right)-\nu_{i}\left(E_{1} g_{2} g_{1}\right)=\left(\nu_{i}\left(E_{1}\right)^{\frac{1}{2}}-\nu_{i}\left(E_{1} g_{2} g_{1}\right)^{\frac{1}{2}}\right) \\
& \cdot\left(\nu_{i}\left(E_{1}\right)^{\frac{1}{2}}+\nu_{i}\left(E_{1} g_{2} g_{1}\right)^{\frac{1}{2}}\right) \leqq 2 s_{i}\left(P_{i 1}+P_{i 2}\right) \tag{3}
\end{align*}
$$

Furthermore, similarly we obtain

$$
\begin{equation*}
\left|\nu_{i}\left(E_{1} g_{3} g_{1}\right)^{\frac{1}{2}}-\nu_{i}\left(E_{1}\right)^{\frac{1}{2}}\right| \leqq P_{i 3}+P_{i 1} \tag{4}
\end{equation*}
$$

Therefore (2) and (4) yield that

$$
\left|\nu_{i}\left(E_{1} g_{2} g_{1}\right)^{\frac{1}{2}}-\nu_{i}\left(E_{1} g_{3} g_{1}\right)^{\frac{1}{2}}\right| \leqq 2 P_{i 1}+P_{i 2}+P_{i 3}
$$

and so $\left|\nu_{i}\left(E_{1} g_{2} g_{1}\right)-\nu_{i}\left(E_{1} g_{3} g_{1}\right)\right| \leqq 2 s_{i}\left(2 P_{i 1}+P_{i 2}+P_{i 3}\right)$. Since $E_{1} g_{3} g_{1} \subset$ $E_{1}-E_{1} g_{2} g_{1}$, we have by (3)

$$
\begin{align*}
\nu_{i}\left(E_{1} g_{2} g_{1}\right) \leqq & 2 s_{i}\left(2 P_{i 1}+P_{i 2}+P_{i 3}\right)+\nu_{i}\left(E_{1} g_{3} g_{1}\right) \\
& \leqq 2 s_{i}\left(3 P_{i 1}+2 P_{i 2}+P_{i 3}\right) \tag{5}
\end{align*}
$$

Thus by (3) and (5),

$$
\begin{align*}
\boldsymbol{\nu}_{i}\left(E_{1}\right)= & \nu_{i}\left(E_{1}-E_{1} g_{2} g_{1}\right)+\boldsymbol{\nu}_{i}\left(E_{1} g_{2} g_{1}\right) \\
& \leqq 2 s_{i}\left(4 P_{i 1}+3 P_{i 1}+P_{i 3}\right) . \tag{6}
\end{align*}
$$

Next, applying to $E_{2}$ the argument similar to that of the preceding paragraph, we obtain

$$
\left|\nu_{i}\left(E_{2} g_{2}\right)^{\frac{1}{2}}-\nu_{i}\left(E_{2} g_{3}\right)^{\frac{1}{2}}\right| \leqq P_{i:}+P_{i 3}
$$

and also $\left|\nu_{i}\left(E_{2} g_{2}\right)-\nu_{i}\left(E_{2} g_{3}\right)\right| \leqq 2 s_{i}\left(P_{i 2}+P_{i 3}\right)$.
But, since $\nu_{i}\left(E_{2}-E_{2} g_{3}\right) \leqq 2 s_{i} P_{i 3}$ and $E_{2} g_{2} \subset E_{2}-E_{2} g_{3}$,

$$
\nu_{i}\left(E_{2} g_{3}\right) \leqq 2 s_{i}\left(P_{i 2}+P_{i 3}\right)+2 s_{i} P_{i 3}=2 s_{i}\left(P_{i 2}+2 P_{i 3}\right)
$$

$$
\begin{equation*}
\nu_{i}\left(E_{2}\right)=\boldsymbol{\nu}_{i}\left(E_{2}-E_{2} g_{3}\right)+\nu_{i}\left(E_{2} g_{3}\right) \leqq 2 s_{i}\left(P_{i 2}+3 P_{i 3}\right) \tag{7}
\end{equation*}
$$

Thus $\quad \nu_{i}\left(E_{2}\right)=\nu_{i}\left(E_{2}-E_{2} g_{3}\right)+\nu_{i}\left(E_{2} g_{3}\right) \leqq 2 s_{i}\left(P_{i 2}+3 P_{i 3}\right)$.
Therefore, (6) and (7) yield that

$$
s_{i}^{2}=\nu_{i}(G)=\nu_{i}\left(E_{1}\right)+\nu_{i}\left(E_{2}\right) \leqq 8 s_{i}\left(P_{i 1}+P_{i 2}+P_{i 3}\right)
$$

and so

$$
s_{i} / 8 \leqq P_{i 1}+P_{i 2}+P_{i 3}
$$

Now, let $g$ be one of $g_{j}^{-1}(j=1,2,3)$ such that $\left[\left[A-A^{\theta g}\right]\right] \geqq\left[\left[A-A^{\theta_{g}-1}\right]\right]$ $(j=1,2,3)$. Then, noting that $\left.\left[\left[A-A^{\theta g_{j}^{1}}\right]\right]\right]^{2}=\sum_{i} P_{i j}^{2}(j=1,2,3)$, we obtain

$$
\begin{aligned}
{\left[\left[A-A^{\theta g}\right]\right]^{2} } & \geqq \frac{1}{3} \sum_{j=1,2,3}\left[\left[A-A^{\theta g_{j}-1}\right]\right]^{2}=\frac{1}{3} \sum_{i}\left(P_{i 1}^{2}+P_{i 2}^{2}+P_{i 3}^{2}\right) \\
& \geqq \frac{1}{3^{2}} \sum_{i}\left(P_{i 1}+P_{i 2}+P_{i 3}\right)^{2} \geqq\left(\sum_{i} s_{i}^{2}\right) / 24^{2}=([[A]] / 24)^{2}
\end{aligned}
$$

However since it holds clearly that $\left[\left[A-A^{\left.\left.\theta_{\sigma}\right]\right]} \leqq 2[[A]]\right.\right.$, we conclude that

$$
[[A]] / 24 \leqq\left[\left[A-A^{\theta g}\right]\right] \leqq 2[[A]] .
$$

Further, since it is evident from the above argument that $k=1 / 24$ does not depend on $A$, the proof is completed.

For each $g \in G=G_{1} * G_{2}$, let $V_{g}$ be the unitary operator on $l_{2}(G)$ defined by $\left[V_{g} f\right]\left(g^{\prime}\right)=f\left(g^{\prime} g\right)\left(f \in l_{2}(G)\right)$. Then it is directly deduced from Lemma 6.2.1 and Lemma 6.3.1 in [1] that the factor $\mathbf{M}$ generated by $\left\{V_{g}\right\}_{g_{g} G}$ is of type $\mathbf{I I}_{1}$ and does not possess the following property (the so-called property ( $\Gamma$ )): Given any system $A_{1}, A_{2}, \ldots \ldots, A_{m} \in \mathbf{M}$ and any $\varepsilon>0$ there exists a unitary $U=U\left(A_{1}, A_{2}, \ldots \ldots, A_{m}\right)$ with $\operatorname{Tr}(U)=0$ and $\left[\left[U^{-1} A_{k} U-A_{k}\right]\right]<\varepsilon$ for $k=1,2, \ldots \ldots, m$. Thus such a factor is not approximately finite. This fact was proved essentially by the following lemma (see [2: Lemma 10] or [1: Lemma 6.2.1]).

LEMMA 5. Let $f(g)$ be a complex-valued function on $G=G_{1} * G_{2}$ such that $\sum_{g e g}|f(g)|^{2}<\infty \quad$ Then there exist $g_{1}, g_{2} \in G$ such that for any $\varepsilon>0$, $\left(\sum_{g \in G}\left|f\left(g_{i}^{-1} g g_{i}\right)-f(g)\right|^{2}\right)^{\frac{1}{2}}<\varepsilon(i=1,2)$ imply $\left(\sum_{\substack{g \in \epsilon \\ g \neq e}}|f(g)|^{2}\right)^{\frac{1}{2}}<k \varepsilon$, where $k$
does not depend on $\varepsilon$.
Using this lemma and Lemma 4, we shall show that the crossed product of the approximately finite factor by the outer automorphic representation of $G=G_{1} * G_{2}$ is of type $\mathbf{I I}_{1}$ and not approximatley finite. That is to say, we see that it is produced a factor of different algebraical type from an original one by the extension of a factor in this manner.

Theorem 2. Let $\mathbf{M}$ be the approximately finite factor and let $G$ be a group of automorphisms of $\mathbf{M}$ which is the outer automorphic representation of the free product of two torsion free countable groups. Then the crossed product of $\mathbf{M}$ by $G$ is of type $\mathbf{I I}_{1}$ and not approximately finite.

PRoof. We shall freely use the definition and the notation with respect to the crossed product in [3]. By [3; Theorem 4], (M,G) is a factor of type $\mathrm{II}_{1}$, and so it remains only to show that it is not approximately finite. Denote by $g_{1}, g_{2}$ the elements of $G$ in Lemma 5 and $g_{3}$ the element of $G$ stated in Lemma 4. Now, assume that the crossed product ( $\mathbf{M}, G$ ) has the property $(\Gamma)$, that is, for any $\varepsilon>0$, there exists a unitary $V=V\left(U_{g_{1}}, U_{y_{2}}\right.$, $U_{g_{3}}$ ) in ( $\mathbf{M}, G$ ) with $\operatorname{Tr}(V)=0$ (where $U_{g_{k}}(k=1,2,3)$ are unitary operators defined in [3: Lemma 2]), and $\left[\left[U_{g_{k}}-V^{-1} U_{g_{k}} V\right]\right]<\varepsilon(k=1,2,3)$. By [3: Theorem 1], $V$ is uniquely expressed in the form $\sum_{y \in G} A_{\theta} U_{\theta}(A \in \mathbf{M} \otimes \mathbf{I})$ in the sense of metric convergence in $(\mathbf{M}, G)$, and $[[V]]=\left(\sum_{y \in f}\left[\left[A_{\theta}\right]\right]^{2}\right)^{\frac{1}{2}}=1$.
Thus

$$
\begin{aligned}
& \varepsilon>\left[\left[U_{g_{k}}-V^{-1} U_{g_{k}} V\right]\right]=\left[\left[V-U_{\theta_{k}} V U_{g_{k}}^{-1}\right]\right] \\
& =\left[\left[\sum_{g \epsilon G} A_{\theta} U_{g}-\sum_{g \epsilon G} A_{g}^{\sigma_{k}} U_{g_{k} g \sigma_{k^{-1}}}\right]\right] \\
& =\left[\left[\sum_{g_{\epsilon G}}\left(A_{g}-A_{U_{k_{k}}-\mathbf{l}_{g g_{k}}}^{g_{k}}\right) U_{g}\right]\right] \\
& =\left(\sum_{g_{\epsilon G}}\left[\left[A-A_{\sigma_{k}-1 g_{k}}^{q_{k}}\right]\right]^{2}\right)^{\frac{1}{2}} .
\end{aligned}
$$

Hence, by Lemma 4, [[ $\left.\left.A_{e}-A_{e}^{q_{s}}\right]\right]<\varepsilon\left(e\right.$; the unit of $G$ ) implies [[ $\left.\left.A_{e}\right]\right]$ $\leqq k_{1} \varepsilon$ where $k_{1}$ does not depend on $\varepsilon$. On the other hand, putting $f(g)=$ $\left[\left[A_{g}\right]\right]=\left[\left[A_{g}^{h}\right]\right](h \in G)$, then

$$
\left(\sum_{g_{\epsilon} G}\left|f\left(g_{k}^{-1} g g_{k}\right)-f(g)\right|^{2}\right)^{\frac{1}{2}} \leqq\left(\sum_{g_{\epsilon G}}\left[\left[A_{g}-A_{\sigma_{k}-1 g g_{k}}^{q_{k}}\right]\right]^{2}\right)^{\frac{1}{2}}<\varepsilon
$$

Applying Lemma 5 , we obtain $\left(\sum_{\substack{g \in \epsilon \\ g \neq e}}\left[\left[A_{g}\right]\right]^{2}\right)^{\frac{1}{2}}=\left(\sum_{\substack{g \epsilon G \\ g \neq e}}|f(g)|^{2}\right)^{\frac{1}{2}}<k_{2} \varepsilon$ where $k_{2}$ does not depend on $\varepsilon$. Therefore we can conclude that

$$
1=[[V]]=\left(\sum_{g_{\epsilon} G}\left[\left[A_{\theta}\right]\right]^{2}\right)^{\frac{1}{2}} \leqq\left[\left[A_{e}\right]\right]+\left(\sum_{\substack{g \in G \\ g \neq e}}\left[\left[A_{g}\right]\right]^{2}\right)^{\frac{1}{2}}<\left(k_{1}+k_{2}\right) \varepsilon .
$$

Hence, choosing $\varepsilon<1 /\left(k_{1}+k_{2}\right)$ we have the contradiction, which completes
the proof.
REMARK. It is readily seen from the preceding argument that the statements analogous to Lemma 4 and Theorem 2 are true for the free product of $n$ arbitary torsion free countable groups ( $n \geqq 2$ ).
