# DEAD-CORE AT TIME INFINITY FOR A HEAT EQUATION WITH STRONG ABSORPTION 

Sheng-Chen Fu, Jong-Shenq Guo* and Chin-Chin Wu<br>Dedicated to Prof. Masayasu Mimura on the occasion of his sixty-fifth birthday

#### Abstract

We study an initial boundary value problem for a heat equation with strong absorption. We first prove that the solution of this problem stays positive for any finite time and converges to the unique steady state for a large class of initial data. This gives an example in which the dead-core is developed in infinite time. Then some estimates of the dead-core rate(s) are derived. Finally, we provide the uniformly exponential rate of convergence of the solution to the unique steady state.

## 1. Introduction

We study the following initial boundary value problem $(\mathrm{P})$ for the heat equation with strong absorption:

$$
\begin{align*}
& u_{t}=u_{x x}-u^{p}, 0<x<1, t>0  \tag{1.1}\\
& u_{x}(0, t)=0, u(1, t)=k_{p}, t>0 \tag{1.2}
\end{align*}
$$

$$
\begin{equation*}
u(x, 0)=u_{0}(x), 0 \leq x \leq 1 \tag{1.3}
\end{equation*}
$$

where $p \in(0,1), k_{p}:=[2 \alpha(2 \alpha-1)]^{-\alpha}, \alpha:=1 /(1-p)$, and $u_{0}$ is a smooth function defined on $[0,1]$ such that

$$
\begin{equation*}
u_{0}^{\prime}(0)=0, u_{0}(1)=k_{p}, u_{0}^{\prime}(x) \geq 0, U(x)<u_{0}(x) \leq k_{p} \text { for } x \in[0,1) \tag{1.4}
\end{equation*}
$$

[^0]We note that the constant $k_{p}$ is chosen so that the unique steady state $U(x):=k_{p} x^{2 \alpha}$ of (1.1)-(1.2) is positive for $x \neq 0$ and $U(0)=0$.

Problem $(\mathrm{P})$ arises in the modelling of an isothermal reaction-diffusion process $[1,10]$ and a description of thermal energy transport in plasma [8, 6]. In the first example, the solution $u$ of $(\mathrm{P})$ represents the concentration of the reactant which is injected with a fixed amount on the boundary $x= \pm 1$ (after a symmetric reflection), and $p$ is the order of reaction.

It is trivial that, for any $u_{0}$ as above, problem ( P ) admits a unique global classical solution. Also, it follows from the strong maximum principle that $u>U$ and $u_{x}>0$ in $(0,1) \times(0, \infty)$.

The problem ( P ) with general boundary values (i.e., any $k>0$ ) has been studied extensively. We refer the reader to a recent work of one of the authors and Souplet [4] and the references cited therein. Recall that the region where $u=0$ is called the dead-core, the first time when $u$ reaches zero is called the dead-core time and the rate of convergence to zero in time is called the dead-core rate. In [4], we studied the case when the dead-core is developed in a finite time. In [4], it is proved that the finite time dead-core rate is always non-self-similar. Indeed, it is shown in [5] that there can be infinitely many different finite time dead-core rates depending on the initial data.

By taking the special constant $k_{p}$, we shall show that the solution of $(\mathrm{P})$ is always positive for all $t>0$ and tends to the unique steady state $U$ uniformly as $t \rightarrow \infty$. In particular, we have $u(0, t) \rightarrow 0$ as $t \rightarrow \infty$. This means that the deadcore occurs at time infinity.

A natural question arises, namely, how the solution $u$ tends to $U$. In particular, we shall investigate the dead-core rate, i.e., the exact convergence rate of $u(0, t)$ to zero as $t \rightarrow \infty$. For some related works, we refer the reader to [2, 3, 9]. We note that there is a singularity in the sense that the reaction rate $u^{p-1}$ tends to infinity when $u$ tends to zero. This causes a certain difficulty in dealing with the problem (P).

This paper is organized as follows. We first study some properties of the solution of $(\mathrm{P})$ in $\S 2$. In particular, we prove that the dead-core is developed at time infinity. In $\S 3$, some properties of the associated steady states to (1.1) are given and some further properties of the solution of $(\mathrm{P})$ in terms of these steady states are also derived. Section 4 is devoted to the spectrum analysis of the linearized operator around the unique steady state $U$ and the related approximated operators to this linearized operator. Then, in $\S 5$, we give some estimates for the dead-core rate(s). Unfortunately, we are unable to derive the exact dead-core rate. We suspect that the dead-core rate might depend on the initial data. We leave this important question as an open problem. Finally, the uniformly exponential rate of convergence of $u$ to $U$ over the whole domain as $t \rightarrow \infty$ is given in $\S 6$.

## 2. Dead-core at Time Infinity

In this section, we shall study some basic properties of the solution $u$ of $(\mathrm{P})$. First, we have the following result of positivity of $u$. This also implies that the dead-core can only be developed at time infinity.

Theorem 2.1. We have $u>0$ for all $0 \leq x \leq 1$ and $t>0$.

Proof. For contradiction, we may assume that

$$
T:=\sup \{\tau>0 \mid u(x, t)>0 \forall(x, t) \in[0,1] \times[0, \tau]\}<\infty
$$

By the maximum principle, we have $u>U$ in $(0,1) \times[0, T]$. In particular,

$$
\begin{equation*}
u(1 / 2, t)>U(1 / 2) \forall t \in[0, T] \tag{2.1}
\end{equation*}
$$

Let $\left\{u_{n}\right\}_{n \geq 1}$ be a sequence of functions defined on $[0,1]$ such that

$$
u_{n}^{\prime \prime}=u_{n}^{p} \quad \text { on }[0,1] ; \quad u_{n}(0)=0, u_{n}^{\prime}(0)=1 / n
$$

It is easy to see that $u_{n} \geq u_{n+1} \geq U$ on $[0,1]$ for all $n \geq 1$. Furthermore, $u_{n} \rightarrow U$ uniformly on $[0,1]$ as $n \rightarrow \infty$. It follows from (2.1) that $u(1 / 2, t)>U_{N}(1 / 2)$ for all $t \in[0, T]$ for some sufficiently large $N$. By choosing $N$ larger (if necessary), we also have

$$
u_{0}(x)>U_{N}(x) \quad \forall x \in[0,1 / 2]
$$

It follows from the maximum principle that $u \geq u_{N}$ on $[0,1 / 2] \times[0, T]$. Since $u(0, T)=0$, we obtain that $u_{x}(0, T) \geq u_{N}^{\prime}(0)>0$, a contradiction. Hence the theorem is proved.

The next theorem shows that $u$ converges to the unique steady state $U$ as $t \rightarrow \infty$. As a consequence, the dead-core does occur at time infinity.

Theorem 2.2. There holds $u(x, t) \rightarrow U(x)$ uniformly for $x \in[0,1]$ as $t \rightarrow \infty$.
Proof. First, we show that $u, u_{x}, u_{t}$ are bounded on $[0,1] \times[0, \infty)$. Indeed, the boundedness of $u$ follows from the maximum principle. Since the function $v:=u_{t}$ satisfies

$$
\begin{aligned}
& v_{t}=v_{x x}-p u^{p-1} v, 0<x<1, t>0 \\
& v_{x}(0, t)=0, v(1, t)=0, t>0 \\
& v(x, 0)=u_{0}^{\prime \prime}(x)-u_{0}^{p}(x), 0 \leq x \leq 1
\end{aligned}
$$

It follows from the maximum principle that $v$ (and so $u_{t}$ ) is bounded on $[0,1] \times$ $[0, \infty)$. Now, from (1.1) we see that $u_{x x}$ is bounded on $[0,1] \times[0, \infty)$. Consequently, $u_{x}$ is also bounded, since $u_{x}(0, t)=0$ for all $t>0$.

Now, we take any sequence $\left\{t_{j}\right\}$ with $t_{j} \rightarrow \infty$ as $j \rightarrow \infty$. We define $u_{j}(x, t):=$ $u\left(x, t+t_{j}\right)$ for any $j \in \mathbb{N}$. From the boundedness of $u$ and $u_{x}$ it follows that $\left\{u_{j}\right\}$ is uniformly bounded and equi-continuous on $[0,1] \times[0, \infty)$. It follows from the Arzela-Ascoli Theorem that there exists a subsequence, still denoted by $u_{j}$, such that $u_{j} \rightarrow w$ uniformly on $[0,1]$ as $j \rightarrow \infty$ for some function $w$ satisfying

$$
\begin{aligned}
& w_{t}=w_{x x}-w^{p}, 0<x<1, t>0 \\
& w_{x}(0, t)=0, w(1, t)=k_{p}, t>0
\end{aligned}
$$

We claim that $w_{t} \equiv 0$. To do this, we introduce the energy functional

$$
E(t):=\frac{1}{2} \int_{0}^{1} u_{x}^{2} d x+\frac{1}{p+1} \int_{0}^{1} u^{p+1} d x
$$

By a simple computation, we have

$$
E^{\prime}(t)=-\int_{0}^{1} u_{t}^{2} d x
$$

For any fixed $T>0$, an integration yields

$$
\int_{0}^{T} \int_{0}^{1} u_{t}^{2} d x d t=E(0)-E(T) \leq E(0)<\infty
$$

It follows that

$$
\int_{0}^{\infty} \int_{0}^{1} u_{t}^{2} d x d t<\infty
$$

This implies that

$$
\int_{0}^{\infty} \int_{0}^{1} u_{j, t}^{2} d x d t=\int_{t_{j}}^{\infty} \int_{0}^{1} u_{t}^{2} d x d t \rightarrow 0 \text { as } j \rightarrow \infty
$$

On the other hand, for any $T>0$, since $\left\{u_{j, t}\right\}_{j \in \mathbb{N}}$ is uniformly bounded in $L^{2}([0,1] \times[0, T])$, it follows that $u_{j, t}$ converges weakly to $w_{t}$ in $L^{2}([0,1] \times[0, T])$. This implies that

$$
\int_{0}^{T} \int_{0}^{1} w_{t}^{2} d x d t \leq \liminf _{j \rightarrow \infty} \int_{0}^{T} \int_{0}^{1} u_{j, t}^{2} d x d t=0
$$

Hence $w_{t} \equiv 0$ and so $w=U$.

Since the sequence $\left\{t_{j}\right\}$ is arbitrary, the theorem follows.
The following theorem implies that the convergence of $u(0, t)$ to zero is at least exponentially fast.

Theorem 2.3. There exist positive constants $C$ and $\beta$ such that

$$
\begin{equation*}
0<u(0, t) \leq C e^{-\beta t} \tag{2.2}
\end{equation*}
$$

for all $t>0$.
Proof. First, following an idea from [9], we derive the following estimate

$$
\begin{equation*}
\int_{0}^{1}[u(x, t)-U(x)]^{2} d x \leq C e^{-\gamma t} \tag{2.3}
\end{equation*}
$$

for all $t>0$ for some positive constants $C$ and $\gamma$. To this end, we set $w=u-U$. Then $w$ satisfies

$$
\begin{aligned}
& w_{t}=w_{x x}+U^{p}-u^{p} \leq w_{x x}, 0<x<1, t>0, \\
& w_{x}(0, t)=0=w(1, t), t>0 .
\end{aligned}
$$

It then follows that

$$
\int_{0}^{1} w w_{t} d x \leq \int_{0}^{1} w w_{x x} d x
$$

Using an integration by parts and applying the Poincare Inequality, we get

$$
\frac{1}{2} \frac{d}{d t} \int_{0}^{1} w^{2} d x \leq-\int_{0}^{1} w_{x}^{2} d x \leq-\frac{\pi^{2}}{4} \int_{0}^{1} w^{2} d x
$$

Hence (2.3) follows with $\gamma=\pi^{2} / 2$.
By a comparison, it suffices to consider the case when $u_{0}(x) \equiv k_{p}$. Recall that $u_{x}>0$ on $(0,1) \times(0, \infty)$. It implies that

$$
\begin{equation*}
u(x, t) \geq u(0, t) \geq U(x)=k_{p} x^{2 \alpha} \forall x \in[0, h(t)], \tag{2.4}
\end{equation*}
$$

where $h(t):=\left[u(0, t) / k_{p}\right]^{1 /(2 \alpha)} \leq 1$ for $t>0$. Then it follows from (2.3) and (2.4) that

$$
\begin{aligned}
C e^{-\gamma t} & \geq \int_{0}^{1}[u(x, t)-U(x)]^{2} d x \\
& \geq \int_{0}^{h(t)}[u(0, t)-U(x)]^{2} d x \\
& =\int_{0}^{h(t)} k_{p}^{2}\left[h(t)^{2 \alpha}-x^{2 \alpha}\right]^{2} d x \\
& =k_{p}^{2} h(t)^{4 \alpha+1} \int_{0}^{1}\left(1-s^{2 \alpha}\right)^{2} d s,
\end{aligned}
$$

by a change of variable $s:=x / h(t)$.
Hence the theorem follows by taking $\beta=2 \alpha \gamma /(4 \alpha+1)$.

## 3. Relations of the Solution to Steady States

Now, for any $\eta \geq 0$, let $U_{\eta}$ be the solution of

$$
\begin{equation*}
u^{\prime \prime}=u^{p}, u>0 \quad \forall y>0 ; \quad u(0)=\eta, u^{\prime}(0)=0 \tag{3.1}
\end{equation*}
$$

In particular, $U_{0}(y)=U(y)=k_{p} y^{2 \alpha}$ for $y \geq 0$. Note that, by a re-scaling, we have

$$
\begin{equation*}
U_{\eta}(y)=\eta U_{1}\left(\eta^{(p-1) / 2} y\right) \quad \forall \eta>0 \tag{3.2}
\end{equation*}
$$

Also, by a simple comparison, we have $U_{\eta_{1}}>U_{\eta_{2}}$ if $\eta_{1}>\eta_{2} \geq 0$. Moreover, $U_{\eta} \rightarrow U_{0}$ as $\eta \rightarrow 0^{+}$.

Concerning the asymptotic behavior of $U_{\eta}$ as $\eta \rightarrow 0^{+}$, we recall from [5] that
Lemma 3.1. As $\eta \rightarrow 0^{+}$,

$$
U_{\eta}(x)=U_{0}(x)+a \eta^{(1-p) / 2} x^{2 \alpha-1}(1+o(1))
$$

for any $x>0$, where $a$ is a positive constant.

In the sequel, for convenience we denote $\sigma(t):=u(0, t)$. The proof of the following lemma is based on a zero number argument (see also Theorem 4.1 of [9]).

Lemma 3.2. For all $t$ sufficiently large, $\sigma(t)$ is strictly decreasing and

$$
\begin{equation*}
u(x, t)<U_{\sigma(t)}(x) \text { in }(0,1] \tag{3.3}
\end{equation*}
$$

Proof. Define $z_{\eta}(x, t):=u(x, t)-U_{\eta}(x)$. Then $z_{\eta}$ satisfies

$$
\left(z_{\eta}\right)_{t}=\left(z_{\eta}\right)_{x x}+c_{\eta}(x, t) z_{\eta}
$$

for some function $c_{\eta}$. Since $z_{\eta}(1, t)<0$ and $\left(z_{\eta}\right)_{x}(0, t)=0$ for all $t>0$, we see that the zero number $J_{\eta}(t)$ of $z_{\eta}$ defined by $J_{\eta}(t):=\#\left\{x \in[0,1] \mid z_{\eta}(x, t)=0\right\}$ is non-increasing in $t$.

We first claim that there exists $\eta^{*}>0$ such that $J_{\eta}(1)=1$ for all $\eta \in\left(0, \eta^{*}\right]$. Indeed, since $z_{0, x}(1,1)<0$, there exists $\delta>0$ such that $z_{0, x}(x, 1)<0$ for all $x \in[1-\delta, 1]$. Since $z_{\eta, x}(x, 1) \rightarrow z_{0, x}(x, 1)$ uniformly on $[0,1]$ as $\eta \rightarrow 0^{+}$, there is $\eta_{0}>0$ such that

$$
\begin{equation*}
z_{\eta, x}(x, 1)<0 \quad \forall x \in[1-\delta, 1] \quad \forall \eta \in\left(0, \eta_{0}\right] \tag{3.4}
\end{equation*}
$$

On the other hand, since $u(x, 1)>U(x)$ on $[0,1-\delta]$ and $U_{\eta} \rightarrow U$ uniformly on $[0,1-\delta]$ as $\eta \rightarrow 0^{+}$, there exists an $\eta^{*} \in\left(0, \eta_{0}\right)$ such that

$$
\begin{equation*}
z_{\eta}(x, 1)>0 \quad \forall x \in[0,1-\delta] \quad \forall \eta \in\left(0, \eta^{*}\right] . \tag{3.5}
\end{equation*}
$$

Recall that $z_{\eta}(1,1)<0$ for all $\eta>0$. We conclude from (3.4) and (3.5) that $J_{\eta}(1)=1$ for all $\eta \in\left(0, \eta^{*}\right]$.

Next, we fix any $\eta \in\left(0, \eta^{*}\right]$. Note that $J_{\eta}(t) \leq 1$ for all $t>1$. We claim that $\sigma\left(t_{0}\right)>\eta$, if $J_{\eta}\left(t_{0}\right)=1$ for some $t_{0}>1$. For contradiction, we suppose that $\sigma\left(t_{0}\right) \leq \eta$, i.e., $u\left(0, t_{0}\right) \leq U_{\eta}(0)$. Note that $u(1, t)<U_{\eta}(1)$ for all $t>0$. If $u\left(0, t_{0}\right)=U_{\eta}(0)$, then $u\left(x, t_{0}\right)<U_{\eta}(x)$ for all $x \in(0,1]$, since $J_{\eta}\left(t_{0}\right)=1$. Since $J_{\eta}(t)=1$ for all $t \in\left[1, t_{0}\right]$, there exists $x(t) \in[0,1)$ such that $u(x(t), t)=U_{\eta}(x(t))$ and $u(x, t)<U_{\eta}(x)$ for $x \in(x(t), 1]$ for each $t \in\left[1, t_{0}\right]$. By Hopf's Lemma, $u_{x}\left(0, t_{0}\right)<U_{\eta}^{\prime}(0)=0$, a contradiction. On the other hand, if $u\left(0, t_{0}\right)<U_{\eta}(0)$, then there exists $t^{*} \in\left(1, t_{0}\right)$ such that $u(0, s)<U_{\eta}(0)$ for all $s \in\left[t^{*}, t_{0}\right]$. Since $u(1, s)<U_{\eta}(1)$, we can find $x(s) \in(0,1)$ such that $u(x(s), s)=U_{\eta}(x(s))$ and $u(x, s)<U_{\eta}(x)$ for $x \neq x(s)$ for all $s \in\left[t^{*}, t_{0}\right]$. This is a contradiction to the maximum principle. This proves that $\sigma\left(t_{0}\right)>\eta$, if $J_{\eta}\left(t_{0}\right)=1$ for some $t_{0}>1$.

Now, since $\sigma(t) \rightarrow 0$ as $t \rightarrow \infty$, there is $t_{1}$ sufficiently large such that $\sigma(t) \leq \eta^{*}$ for all $t \geq t_{1}$. Hence $J_{\sigma(t)}(t)=0$ for all $t \geq t_{1}$. This implies that

$$
u(x, t)<U_{\sigma(t)}(x) \quad \text { on }[0,1]
$$

for all $t \geq t_{1}$. Therefore, (3.3) follows. Moreover, $J_{\sigma(t)}(s)=0$ for all $s>t \geq t_{1}$. Then $u(x, s)<U_{\sigma(t)}(x)$ for $x \in[0,1]$. In particular,

$$
\sigma(s)=u(0, s)<U_{\sigma(t)}(0)=\sigma(t)
$$

and the lemma is proved.
Indeed, we have the convergence of $u(x, t)$ to $U_{\sigma(t)}(x)$ near $x=0$ as $t \rightarrow \infty$. To prove this, we make the following transformations:

$$
\begin{equation*}
u(x, t):=\sigma(t) \theta(\xi, \tau), \quad \xi:=\sigma(t)^{(p-1) / 2} x, \quad \tau:=\int_{0}^{t} \sigma(s)^{p-1} d s \tag{3.6}
\end{equation*}
$$

Then it is easy to check that $\theta$ satisfies the equation

$$
\begin{equation*}
\theta_{\tau}=\theta_{\xi \xi}-\theta^{p}-g(\tau)\left(\theta-\frac{1-p}{2} \xi \theta_{\xi}\right) \tag{3.7}
\end{equation*}
$$

where $g(\tau):=\sigma^{\prime}(t) \sigma(t)^{-p}$. Also, $\theta(0, \tau)=1$ and $\theta_{\xi}(0, \tau)=0$ for all $\tau>0$. Moreover, it follows from Lemma 3.2 and (3.2) that $\theta(\xi, \tau)<U_{1}(\xi)$.

We shall study the stabilization of the solution $\theta$ of (3.7). First, by considering the function

$$
J(x, t):=\frac{1}{2} u_{x}^{2}-C u^{p+1}
$$

for some positive constant $C$ and applying a maximum principle (cf. p. 660 of [4]), we can also derive the following estimate

$$
\begin{equation*}
0 \leq u_{x} \leq C u^{(p+1) / 2} \forall x \in[0,1], t>0 \tag{3.8}
\end{equation*}
$$

where $C$ is a positive constant. Consequently, by an integration, we deduce from (3.8) that

$$
\begin{equation*}
u(x, t) \leq\left[\sigma(t)^{(1-p) / 2}+c x\right]^{2 \alpha} \forall x \in[0,1], t>0 \tag{3.9}
\end{equation*}
$$

for some positive constant $c$.
Using (3.9), (3.6), and $u_{x}=\sigma^{(1+p) / 2} \theta_{\xi}$, we obtain the following estimate for the solution $\theta$ of (3.7):

$$
\begin{equation*}
0 \leq \xi \theta_{\xi}(\xi, \tau), \theta(\xi, \tau) \leq C(1+\xi)^{2 \alpha} \forall \xi \in\left[0, \sigma^{(p-1) / 2}(t)\right], \tau>0 \tag{3.10}
\end{equation*}
$$

for some positive constant $C$.
Next, it follows from the Hopf Lemma that $u_{x x}(0, t)>0$ and so $u_{t}(0, t)>$ $-u^{p}(0, t)$ by (1.1). Hence $g(\tau)>-1$ for all $\tau>0$. We conclude from Lemma 3.2 that $-1<g(\tau)<0$ for all $\tau \gg 1$. Note that

$$
\int_{0}^{\infty} g(\tau) d \tau=-\infty
$$

Nevertheless, we have the following lemma.
Lemma 3.3. There holds $\lim _{\tau \rightarrow \infty} g(\tau)=0$.
Proof. Otherwise, there is a sequence $\left\{\tau_{n}\right\} \rightarrow \infty$ such that $g\left(\tau_{n}\right) \rightarrow-\gamma$ as $n \rightarrow \infty$ for some constant $\gamma>0$. By using (3.10) and the standard regularity theory, we can show that there is a subsequence, still denote it by $\left\{\tau_{n}\right\}$, such that

$$
\theta\left(\xi, \tau+\tau_{n}\right) \rightarrow \tilde{\theta}(\xi, \tau) \text { as } n \rightarrow \infty
$$

uniformly on any compact subsets, where $\tilde{\theta}$ solves the equation

$$
\begin{equation*}
\tilde{\theta}_{\tau}=\tilde{\theta}_{\xi \xi}-\tilde{\theta}^{p}+\gamma\left(\tilde{\theta}-\frac{1-p}{2} \xi \tilde{\theta}_{\xi}\right), \xi>0, \tau>0 \tag{3.11}
\end{equation*}
$$

with $\tilde{\theta}(0, \tau)=1$ and $\tilde{\theta}_{\xi}(0, \tau)=0$. Moreover, it is easily to check that $\tilde{\theta} \leq U_{1}$ and $\tilde{\theta}_{\xi} \geq 0$.

Furthermore, it follows from the so-called energy argument (cf. the proof of Proposition 3.1 in [4]) that $\tilde{\theta}(\xi, \tau) \rightarrow V(\xi)$ as $\tau \rightarrow \infty$ for some $V$ satisfying

$$
\begin{aligned}
& V^{\prime \prime}-V^{p}+\gamma\left(V-\frac{1-p}{2} \xi V^{\prime}\right)=0, \xi>0, \\
& V^{\prime}(0)=0, V(0)=1 .
\end{aligned}
$$

Note that $V \leq U_{1}$ and $V^{\prime} \geq 0$. Set

$$
W(y):=\left(\frac{\gamma}{\alpha}\right)^{\alpha} V\left(\sqrt{\frac{\alpha}{\gamma}} y\right) .
$$

Then $W$ satisfies

$$
\begin{aligned}
& W^{\prime \prime}-W^{p}+\alpha\left(W-\frac{1-p}{2} y W^{\prime}\right)=0, y>0, \\
& W^{\prime}(0)=0, W(0)=(\gamma / \alpha)^{\alpha} .
\end{aligned}
$$

Since $W>0, W^{\prime} \geq 0$ for $y>0$, and $V \leq U_{1}$ gives the polynomial boundedness of $W$, it follows from Proposition 3.3 of [4] that either $W=U$ or $W \equiv \alpha^{-\alpha}$. The first case is impossible, since $U(0)=0$. The second case is also impossible, since $\theta$ is unbounded by Theorem 2.2. Hence the lemma follows.

Again, by the standard limiting process with the estimate (3.10) and Lemma 3.3, for any given sequence $\left\{\tau_{n}\right\} \rightarrow \infty$, we can show that there is a limit $\tilde{\theta}$ satisfying

$$
\begin{aligned}
& \tilde{\theta}_{\tau}=\tilde{\theta}_{\xi \xi}-\tilde{\theta}^{p}, \xi>0, \tau>0, \\
& \tilde{\theta}(0, \tau)=1, \tilde{\theta}_{\xi}(0, \tau)=0,
\end{aligned}
$$

such that $\theta\left(\xi, \tau+\tau_{n}\right) \rightarrow \tilde{\theta}(\xi, \tau)$ as $n \rightarrow \infty$ uniformly on compact subsets. Since we also have

$$
\tilde{\theta}(\xi, \tau) \leq U_{1}(\xi), \tilde{\theta}(0, \tau)=U_{1}(0), \tilde{\theta}_{\xi}(0, \tau)=\left(U_{1}\right)_{\xi}(0)
$$

the Hopf Lemma implies that $\tilde{\theta} \equiv U_{1}$. Since this limit is independent of the given sequence $\left\{\tau_{n}\right\}$, we see that $\theta(\xi, \tau) \rightarrow U_{1}(\xi)$ as $\tau \rightarrow \infty$ uniformly on any compact subsets. Returning to the original variables and using the relation (3.2), we thus have proved the following so-called inner expansion.

Theorem 3.4. As $t \rightarrow \infty$, we have

$$
u(x, t)=U_{\sigma(t)}(x)(1+o(1))
$$

uniformly in $\left\{0 \leq \sigma^{(p-1) / 2}(t) x \leq C\right\}$ for any positive constant $C$.

## 4. Spectrum Analysis

In this section, we shall study the following linearized operator

$$
\mathcal{L} v:=-v^{\prime \prime}+\frac{b}{x^{2}} v, b:=(2 \alpha-1)(2 \alpha-2)
$$

which is from the linearization of (1.1) around the steady state $U$.
Consider the eigenvalue problem

$$
\begin{equation*}
\mathcal{L} \phi=\lambda \phi, 0<x<1 ; \quad \phi^{\prime}(0)=0, \phi(1)=0 \tag{4.1}
\end{equation*}
$$

We introduce the following Hilbert space and quantities:

$$
\begin{aligned}
& \mathbb{H}:=\left\{\phi \in H^{1}([0,1]) \left\lvert\, \int_{0}^{1} \frac{\phi^{2}(x)}{x^{2}} d x<\infty\right., \phi(1)=0\right\} \\
& J(\phi):=\int_{0}^{1} \phi_{x}^{2}(x) d x+b \int_{0}^{1} \frac{\phi^{2}(x)}{x^{2}} d x, \quad I(\phi):=\int_{0}^{1} \phi^{2}(x) d x
\end{aligned}
$$

Then the principal eigenvalue $\lambda^{*}$ of (4.1) can be characterized by

$$
\begin{equation*}
\lambda^{*}:=\inf \{J(\phi) / I(\phi) \mid \phi \in \mathbb{H}, I(\phi)>0\} \tag{4.2}
\end{equation*}
$$

It is easy to see that $\lambda^{*}>b>0$. Also, by taking a minimization sequence, we can show that this $\lambda^{*}$ can be attained by a function $\phi^{*} \in \mathbb{H}$ which is the eigen-function of (4.1) such that

$$
\phi^{*}>0 \text { in }(0,1), \quad \int_{0}^{1}\left(\phi^{*}(x)\right)^{2} d x=1
$$

Note that $\phi^{*}(0)=0$. It is also easy to see that

$$
\begin{equation*}
\phi^{*}(x)=d x^{2 \alpha-1}(1+o(1)) \text { as } x \rightarrow 0 \tag{4.3}
\end{equation*}
$$

for some positive constant $d$.
On the other hand, it is easily seen that for any $\epsilon \in(0,1)$ there exists the principal eigen-pair $\left(\lambda_{\epsilon}, \phi_{\epsilon}\right)$ of the following eigenvalue problem ${ }^{1}$

$$
\begin{equation*}
\mathcal{L}_{\epsilon} \phi_{\epsilon}=\lambda_{\epsilon} \phi_{\epsilon}, 0<x<1 ; \quad \phi_{\epsilon}^{\prime}(0)=\phi_{\epsilon}(1)=0<\phi_{\epsilon}(x) \forall x \in(0,1) \tag{4.4}
\end{equation*}
$$

where

$$
\mathcal{L}_{\epsilon} v:=-v^{\prime \prime}+\frac{b(1-\epsilon)}{x^{2}} \chi_{[\epsilon, 1]}(x) v
$$

and $\chi$ is the indicator function. Note that $\phi_{\epsilon}$ is only a $C^{1}$ function on $[0,1]$ and $\phi_{\epsilon}^{\prime \prime}$ has a jump discontinuity at $x=\epsilon$.

This approximated eigenvalue problem was suggested by an anonymous referee which we would like to acknowledge here.

Lemma 4.1. There holds $\lambda_{\epsilon} \rightarrow \lambda^{*}$ as $\epsilon \rightarrow 0^{+}$.
Proof. By the characterization of the principal eigenvalue $\lambda_{\epsilon}$ of (4.4) and $I\left(\phi^{*}\right)=1$, we have

$$
\lambda_{\epsilon} \leq J_{\epsilon}\left(\phi^{*}\right),
$$

where

$$
J_{\epsilon}(\phi):=\int_{0}^{1} \phi_{x}^{2}(x) d x+b(1-\epsilon) \int_{\epsilon}^{1} \frac{\phi^{2}(x)}{x^{2}} d x
$$

It is clear that $J_{\epsilon}\left(\phi^{*}\right)<J\left(\phi^{*}\right)$. Hence $\lambda_{\epsilon}<\lambda^{*}$ for all $\epsilon>0$ and so

$$
\begin{equation*}
\limsup _{\epsilon \rightarrow 0^{+}} \lambda_{\epsilon} \leq \lambda^{*} \tag{4.5}
\end{equation*}
$$

On the other hand, we introduce a $C^{\infty}$-function $\theta$ by $\theta(s)=0$ for $s \leq 1 / 2$, $\theta(s)_{\tilde{\phi}_{\epsilon}}=1$ for $s \geq 1$, and $\theta^{\prime} \geq 0$ in $[1 / 2,1]$. Let $\theta_{\epsilon}(x):=\theta(x / \epsilon)$ for any $\epsilon \in(0,1)$. Set $\tilde{\phi}_{\epsilon}=\phi_{\epsilon}$ in $[\epsilon, 1]$ and $\tilde{\phi}_{\epsilon}=\epsilon$ in $[0, \epsilon]$. Then for $\psi_{\epsilon}:=\theta_{\epsilon} \tilde{\phi}_{\epsilon}$ we have

$$
\begin{aligned}
& J\left(\psi_{\epsilon}\right) \leq J_{\epsilon}\left(\phi_{\epsilon}\right)+b \epsilon \int_{\epsilon}^{1} \frac{\phi_{\epsilon}^{2}(x)}{x^{2}} d x+\epsilon\left(\int_{1 / 2}^{1}\left(\theta^{\prime}\right)^{2}(s) d s+b \int_{1 / 2}^{1} \frac{\theta^{2}(s)}{s^{2}} d s\right) \\
& I\left(\psi_{\epsilon}\right)=\int_{\epsilon}^{1} \phi_{\epsilon}^{2}(x) d x+\epsilon^{3} \int_{1 / 2}^{1} \theta^{2}(s) d s
\end{aligned}
$$

Since $\lambda^{*} \leq J\left(\psi_{\epsilon}\right) / I\left(\psi_{\epsilon}\right)$ for all $\epsilon \in(0,1)$, we conclude that

$$
\begin{equation*}
\lambda^{*} \leq \liminf _{\epsilon \rightarrow 0^{+}} \lambda_{\epsilon} \tag{4.6}
\end{equation*}
$$

Therefore, the lemma follows by combining (4.5) and (4.6).

## 5. Dead-core Rate Estimates

In this section, we shall give some estimates of the dead-core rate. First, the upper bound of dead-core rate can be derived from Theorem 2.3. that

$$
\limsup _{t \rightarrow \infty} \frac{\ln \sigma(t)}{t} \leq-2 \alpha \cdot \frac{\pi^{2}}{2(4 \alpha+1)}
$$

Next, we derive the following lower bound estimate for $u-U$.
Lemma 5.1. There exists a small positive constant $\delta$ such that

$$
\begin{equation*}
u(x, t)-U(x) \geq \delta e^{-\lambda^{*} t} \phi^{*}(x), x \in[0,1], t>1 \tag{5.1}
\end{equation*}
$$

Proof. Write $w=u-U$. Then $w(0, t)>0, w(1, t)=0$, and $w$ satisfies the equation

$$
\begin{equation*}
w_{t}=w_{x x}-\frac{b}{x^{2}} w+F(x, w) \tag{5.2}
\end{equation*}
$$

where

$$
\begin{equation*}
F(x, w):=U^{p}-(w+U)^{p}+\frac{b}{x^{2}} w=\frac{1}{2} p(1-p) \tilde{U}^{p-2} w^{2} \tag{5.3}
\end{equation*}
$$

for some $\tilde{U} \in(U, U+w)$. Note that $F \geq 0$. Set $\hat{w}(x, t):=\delta e^{-\lambda^{*} t} \phi^{*}(x)$, where $\delta$ is a positive constant to be determined later. Then

$$
\begin{aligned}
& \hat{w}_{t}=\hat{w}_{x x}-\frac{b}{x^{2}} \hat{w}, x \in(0,1), t>0 \\
& \hat{w}(0, t)=0, \hat{w}(1, t)=0, t>0
\end{aligned}
$$

Recall that $\left(\phi^{*}\right)^{\prime}(1)<0$. Also, note that $u_{x}(1,1)-U^{\prime}(1)<0$, by the Hopf Lemma. By the continuity, there exist positive constants $\delta$ and $\eta$ such that

$$
\begin{equation*}
u_{x}(x, 1)-U^{\prime}(x)-\delta e^{-\lambda^{*}}\left(\phi^{*}\right)^{\prime}(x)<0 \tag{5.4}
\end{equation*}
$$

for all $x \in[1-\eta, 1]$. It follows from (5.4) that $w(x, 1) \geq \hat{w}(x, 1)$ for all $x \in$ $[1-\eta, 1]$. Using $u(\cdot, 1)>U(\cdot)$ in $[0,1-\eta]$ and by choosing smaller positive $\delta$ (if necessary), we obtain that $w(x, 1) \geq \hat{w}(x, 1)$ for all $x \in[0,1]$. Therefore, by the comparison principle, the estimate (5.1) follows.

For the lower bound of dead-core rate, we recall from Lemmas 3.1 and 3.2 that for any $x>0$ :

$$
\begin{equation*}
u(x, t) \leq U_{\sigma(t)}(x)=U(x)+a \sigma^{(1-p) / 2}(t) x^{2 \alpha-1}(1+o(1)) \text { as } t \rightarrow \infty \tag{5.5}
\end{equation*}
$$

On the other hand, by (5.1) and (4.3), we have

$$
\begin{equation*}
u(x(t), t) \geq U(x(t))+d \delta e^{-2 \alpha \lambda^{*} t}(1+o(1)) \text { as } t \rightarrow \infty \tag{5.6}
\end{equation*}
$$

where $x(t):=e^{-\lambda^{*} t}$. Consequently, there exists a positive constants $d_{1}$ such that

$$
e^{-\lambda^{*} t} \leq d_{1} \sigma^{(1-p) / 2}(t)(1+o(1)) \text { as } t \rightarrow \infty
$$

Hence we obtain that

$$
\begin{equation*}
\sigma(t) \geq d_{2} e^{-2 \alpha \lambda^{*} t}(1+o(1)) \text { as } t \rightarrow \infty \tag{5.7}
\end{equation*}
$$

for some positive constant $d_{2}$. This implies that

$$
\liminf _{t \rightarrow \infty} \frac{\ln \sigma(t)}{t} \geq-2 \alpha \lambda^{*}
$$

## 6. Rate of Convergence

Recall the principal eigen-pair $\left(\lambda_{\epsilon}, \phi_{\epsilon}\right)$ of (4.4) for any $\epsilon \in(0,1)$. Hereafter we shall fix the eigenfunction $\phi_{\epsilon}$ so that

$$
\phi_{\epsilon}>0 \text { in }(0,1), \quad \int_{0}^{1} \phi_{\epsilon}^{2}(x) d x=1
$$

Then it is clear that $\phi_{\epsilon} \rightarrow \phi^{*}$ in $C^{0}([0,1])$ as $\epsilon \rightarrow 0^{+}$. Then we have the following lemma for the upper bound of $u-U$.

Lemma 6.1. For each $\epsilon \in(0,1)$, there exist positive constants $c_{\epsilon}$ and $t_{\epsilon}$ such that

$$
\begin{equation*}
u(x, t)-U(x) \leq c_{\epsilon} e^{-\lambda_{\epsilon} t} \phi_{\epsilon}(x), x \in[0,1], t \geq t_{\epsilon} \tag{6.1}
\end{equation*}
$$

Proof. Again, we set $w=u-U$. We first estimate $F$ as follows. Since $\tilde{U} \in(U, U+w)$, we compute from (5.3) that

$$
F(x, w) \leq \frac{1-p}{2}\left[U^{-1} w\right]\left[p U^{p-1} w\right]=\frac{1-p}{2}\left[U^{-1} w\right]\left(\frac{b}{x^{2}} w\right)
$$

By Theorem 2.2, there is $t_{\epsilon}$ sufficiently large such that

$$
\frac{1-p}{2}\left[U^{-1}(x) w(x, t)\right] \leq \epsilon \quad \forall x \in[\epsilon, 1], t \geq t_{\epsilon}
$$

Consequently, we obtain from (5.2) that $w$ satisfies the following inequality

$$
\begin{equation*}
w_{t} \leq w_{x x}-\frac{b(1-\epsilon)}{x^{2}} w \forall x \in[\epsilon, 1), t \geq t_{\epsilon} \tag{6.2}
\end{equation*}
$$

Note that $w_{x}(0, t)=w(1, t)=0$ for all $t>0$. Since $u>U$, we have $w_{t}-w_{x x} \leq 0$ for all $x \in[0,1]$.

Now, set $\hat{w}(x, t):=c_{\epsilon} e^{-\lambda_{\epsilon} t} \phi_{\epsilon}(x)$, where $c_{\epsilon}$ is a positive constant to be determined. Then

$$
\begin{aligned}
& \hat{w}_{t}=\hat{w}_{x x}-\frac{b(1-\epsilon)}{x^{2}} \chi_{[\epsilon, 1]}(x) \hat{w}, x \in(0,1), t>0 \\
& \hat{w}_{x}(0, t)=0, \hat{w}(1, t)=0, t>0
\end{aligned}
$$

Recall that $\left(\phi_{\epsilon}\right)^{\prime}(1)<0$. Then by the continuity there exist a small positive constant $\eta$ and a large positive constant $c_{\epsilon}$ such that

$$
\begin{equation*}
u_{x}\left(x, t_{\epsilon}\right)-U^{\prime}(x)-c_{\epsilon} e^{-\lambda_{\epsilon} t_{\epsilon}}\left(\phi_{\epsilon}\right)^{\prime}(x)>0 \quad \forall x \in[1-\eta, 1] \tag{6.3}
\end{equation*}
$$

It follows from (6.3) that $w\left(x, t_{\epsilon}\right) \leq \hat{w}\left(x, t_{\epsilon}\right)$ for $x \in[1-\eta, 1]$. Then, by choosing $c_{\epsilon}$ larger (if necessary), we obtain that $w\left(x, t_{\epsilon}\right) \leq \hat{w}\left(x, t_{\epsilon}\right)$ for $x \in[0,1]$. Therefore, the lemma follows by applying the comparison principle for weak solutions (cf. [7]).

Since $u>U$, we have the following uniformly exponential rate of convergence of $u$ to $U$ over the whole domain by using (5.1) and (6.1).

Theorem 6.2. For each $\epsilon>0$, there exist positive constants $d$ and $d_{\epsilon}$ such that

$$
\begin{align*}
& \|u(\cdot, t)-U\|_{C^{0}([0,1])} \geq d e^{-\lambda^{*} t} \text { for all } t>1  \tag{6.4}\\
& \|u(\cdot, t)-U\|_{C^{0}([0,1])} \leq d_{\epsilon} e^{-\lambda_{\epsilon} t} \text { for all } t>t_{\epsilon} \tag{6.5}
\end{align*}
$$

Indeed, the constants $d$ and $d_{\epsilon}$ in Theorem 6.2 can be taken as $d=\delta \phi^{*}(1 / 2)$ and $d_{\epsilon}=c_{\epsilon}\left\|\phi_{\epsilon}\right\|_{C^{0}([0,1])}$. Notice that $\lambda_{\epsilon}<\lambda^{*}$ for all $\epsilon>0$ and $\lambda_{\epsilon} \rightarrow \lambda^{*}$ as $\epsilon \rightarrow 0^{+}$.
