Aspects of Incompleteness

Springer

Editorial Policy

§1. Submissions are invited in the following categories:

- i) Research monographs
- ii) Lecture and seminar notes
- iii) Reports of meetings
- iv) Texts which are out of print.

Those considering a project which might be suitable for the series are strongly advised to contact the publisher or the series editors at an early stage.

§2. Categories i) and ii). These categories will be emphasized by Lecture Notes in Logic and are normally reserved for works written by one or two authors. The goal is to report new developments – quickly, informally, and in a way that will make them accessible to non-specialists. In the evaluation of submissions timeliness of the work is an important criterion. Texts should be well-rounded and reasonably self-contained. In most cases the work will contain results of others as well as those of the authors. In each case the author(s) should provide sufficient motivation, examples, and applications. In this respect, articles intended for a journal and Ph.D. theses will usually be deemed unsuitable for the Lecture Notes series. Proposals for volumes in this category should be submitted (preferably in duplicate) either to one of the series editors or to Springer-Verlag, Heidelberg, and will be refereed. A provisional judgment on the acceptability of a project can be based on partial information about the work: a detailed outline describing the contents of each chapter, the estimated length, a bibliography, and one or two sample chapters – or a first draft. A final decision whether to accept will rest on an evaluation of the completed work which should include

- at least 100 pages of text;
- a table of contents;
- an informative introduction perhaps with some historical remarks which should be accessible to readers unfamiliar with the topic treated;
- a subject index.

§3. Category iii). Reports of meetings will be considered for publication provided that they are both of exceptional interest and devoted to a single topic. In exceptional cases some other multi-authored volumes may be considered in this category. One (or more) expert participants will act as the scientific editor(s) of the volume. They select the papers which are suitable for inclusion and have them individually refereed as for a journal. Papers not closely related to the central topic are to be excluded. Organizers should contact Lecture Notes in Logic at the planning stage.

§4. Category iv). This category provides an avenue whereby books which have gone out of print but which are still in demand can be made available to the new generations of logicians.

§5. Format. Works in English are preferred. They should be submitted in camera-ready form according to Springer-Verlag's specifications. Technical instructions and/or TeX macros will be sent on request.

PREFACE

By Gödel's incompleteness theorem there is no complete axiomatization of mathematics, not even of first order arithmetic. This leads naturally to the project of investigating the family of, inevitably incomplete, arithmetical theories. In this book we present some of the results obtained in pursuing this aim. A brief summary of the contents of the book is given in the introduction.

Gödel's main idea was to translate metamathematical statements, concerning formulas, formal theories, provability in such theories etc., into arithmetic – the arithmetization of metamathematics. Combining this with the technique of self-reference, he was able to construct a (formal) sentence which is undecidable, neither provable nor disprovable, in a given theory T of arithmetic, thereby demonstrating, in an entirely novel way, that T is incomplete.

The ideas developed by Gödel proved fruitful far beyond their original application. Later essentially new ideas were added. Most important are the basic concepts (and results) of recursion theory – these are needed for a completely general formulation (and proof) of Gödel's theorem – notable are also the so called partial truth-definitions, the idea of formalizing the proof of the completeness of first order logic in arithmetic, and the general concept of interpretability.

In this book we shall be concerned almost exclusively with properties that are common to all sufficiently strong, axiomatizable theories. Thus, for example, investigations of particular theories such as, for example, Peano Arithmetic and its fragments, requiring special, model-theoretic or proof-theoretic, methods, fall outside the scope of the book. But even so, the choice of material in some respects reflects the author's preferences; this is particularly true of Chapter 7.

Credits for results, proofs, and exercises, remarks on alternative proofs, related results, etc. are given in the notes following each chapter. Results (exercises) not attributed to anyone are either easy, folklore, or due to the author.

The reader is assumed to be acquainted with (first order) predicate logic including Henkin's completeness proof. We also presuppose knowledge of the elements of recursion theory. Finally, the reader may find our presentation difficult to follow unless (s)he has previously seen a more detailed development of formal arithmetic, an explicitly defined arithmetization of metamathematics, and a full proof of Gödel's theorem.

I am grateful to Daniel Vallström and Rineke Verbrugge; they have very kindly and carefully read substantial portions of this book, pointed out numerous (minor) errors and suggested many improvements. The responsibility for the blemishes that remain is, of course, mine.

May 1997.
