§ 1. Introduction

In our previous paper [5], we have proposed the problem to determine characteristic classes of differentiable fibre bundles whose fibres are diffeomorphic to a given closed manifold $M$, in other words the problem to compute the cohomology group $H^*(B\text{Diff}M)$. The case when $M$ is a closed orientable surface of genus greater than or equal to two has been treated in [4][5]. In this paper we consider the case when $M$ is the 2-dimensional torus $T^2$. Let $\text{Diff}^+T^2$ be the group of all orientation preserving diffeomorphisms of $T^2$ equipped with the $C^\infty$ topology. Then our main result is

\textbf{Theorem 1.1.}

\[
\dim \tilde{H}^n(B\text{Diff}^+T^2; \mathbb{Q}) = \begin{cases} 
0 & n \not\equiv 1 \pmod{4} \\
2m - 1 & n = 24m + 1 \\
2m + 1 & n = 24m + 5, 24m + 9, 24m + 13 \\
2m + 3 & n = 24m + 21.
\end{cases}
\]

The first non-trivial group is $H^5(B\text{Diff}^+T^2; \mathbb{Q}) \cong \mathbb{Q}$ and $\dim H^{4k+1}(B\text{Diff}^+T^2; \mathbb{Q})$ is approximately $\frac{1}{8} k$. Obviously the ring structure on $H^*(B\text{Diff}^+T^2; \mathbb{Q})$ defined by the cup product is trivial. We can also obtain informations on the torsions and by making use of them we obtain

\textbf{Theorem 1.2.} Mod 2 and 3 torsions, we have

\[
\tilde{H}_n(B\text{Diff}^+T^2; \mathbb{Z}) = \begin{cases} 
torsion & n \equiv 0 \pmod{4} \\
free abelian group of rank indicated in Theorem 1.1 & n \equiv 1 \pmod{4} \\
0 & n \equiv 2, 3 \pmod{4}.
\end{cases}
\]

Received January 24, 1985.
Moreover it turns out that $p$-torsions appear in $H_{4i}(B \text{Diff}^+_T; \mathbb{Z})$ for any prime $p$ (see Remark 5.2 for more precise statements).

The proof of the above theorems consists of elementary but pleasant computations in linear algebra. Finally we remark that the remaining case when $M=S^2$ should be well-known because of Smale's theorem [7]: $\text{Diff}^+_S \cong SO(3)$.

§ 2. $T^2$-bundles

Let $\text{Diff}_0 T^2$ be the connected component of the identity of $\text{Diff}_+ T^2$. Then as is well-known the factor group $\text{Diff}_+ T^2 / \text{Diff}_0 T^2$, which is the mapping class group of $T^2$, can be naturally identified with $SL_2 \mathbb{Z}$. Therefore we have a fibration

$$B \text{Diff}_0 T^2 \longrightarrow B \text{Diff}_+ T^2 \longrightarrow K(SL_2 \mathbb{Z}, 1).$$

$T^2$ acts on itself by "translations" and hence it can be considered as a subgroup of $\text{Diff}_0 T^2$. It is easy to see that the action by conjugations of $SL_2 \mathbb{Z}$ on this subgroup $T^2 \subset \text{Diff}_0 T^2$ is the same as the standard one. Now Earle and Eells [3] proved that the inclusion $T^2 \subset \text{Diff}_0 T^2$ is a homotopy equivalence so that $B \text{Diff}_0 T^2$ has the homotopy type of $K(\mathbb{Z}, 2)$. Hence if we choose suitable elements $x, y \in H^2(B \text{Diff}_0 T^2; \mathbb{Z})$, we can write

$$H^*(B \text{Diff}_0 T^2; \mathbb{Z}) = \mathbb{Z}[x, y]$$
on which $SL_2 \mathbb{Z}$ acts through the automorphism of it given by $\gamma \mapsto \gamma^{-1}$ ($\gamma \in SL_2 \mathbb{Z}$).

Now let $\{E^*: t \in \mathbb{Z}^+ \}$ be the Serre spectral sequence for cohomology (with coefficients in a commutative ring $R$) of the fibration $(\ast)$. Then by the above argument, The $E_2$-term is given by

$$\bigoplus_{t \geq 0} E^2_{2t, t} = H^t(SL_2 \mathbb{Z}; R[x, y]).$$

As is well-known the abelianization $H_1(SL_2 \mathbb{Z})$ of $SL_2 \mathbb{Z}$ is a cyclic group of order 12 and the kernel of the natural surjection $SL_2 \mathbb{Z} \rightarrow H_1(SL_2 \mathbb{Z})$ is the commutator subgroup of $SL_2 \mathbb{Z}$, which in turn is isomorphic to a free group of rank 2 (see [6] for example). Hence applying the standard argument of group cohomology (see e.g. Proposition 10.1 of [1]), we obtain

**Proposition 2.1.** If $s \geq 2$, then $\bigoplus_{t \geq 0} E^s_{2t, t} = H^s(SL_2 \mathbb{Z}; R[x, y])$ is annihilated by 12. In particular if $R = \mathbb{Q}$ or $\mathbb{Z}/n$ with $(n, 12) = 1$, then

$$\bigoplus_{t \geq 0} E^s_{2t, t} = H^s(SL_2 \mathbb{Z}; R[x, y]) = 0 \quad \text{for } s \geq 2.$$
Corollary 2.2. Let \( k = \mathbb{Q} \) or \( \mathbb{Z}_p \) (\( p \) is a prime different from 2 and 3). Then

\[
H^n(B \text{Diff}_+ T^2; k) \cong E_2^n \oplus E_2^n - 1.
\]

§ 3. Lemmas

As is well-known \( SL_2 \mathbb{Z} \) has the following presentation (see [6])

\[
SL_2 \mathbb{Z} = \langle \alpha, \beta; \alpha^4 = \alpha^2 \beta^{-8} = 1 \rangle.
\]

Here, for the convenience of later computations, we choose two generators \( \alpha = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \) and \( \beta = \begin{pmatrix} 0 & 1 \\ -1 & 1 \end{pmatrix} \). The action of \( SL_2 \mathbb{Z} \) on \( H^*(B \text{Diff}_0 T^2; \mathbb{Z}) = \mathbb{Z}[x, y] \) is given by

\[
\alpha(x) = -y, \quad \alpha(y) = x
\]
\[
\beta(x) = x - y, \quad \beta(y) = x
\]

because \( t \alpha^{-1} = \alpha \) and \( t \beta^{-1} = \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix} \).

Now for each \( q \in \mathbb{N} \), let \( L_q \) be the submodule of \( \mathbb{Z}[x, y] \) consisting of homogeneous elements of degree \( 2q \). We choose a basis \( \{ x^q, x^{q-1}y, \ldots, xy^{q-1}, y^q \} \) for \( L_q \) and let

\[
A_q, B_q \in SL_{q+1} \mathbb{Z}
\]
be the matrix representations of the actions of \( \alpha \) and \( \beta \) on \( L_q \) with respect to the above basis. Let \( p \) denotes either a prime or 0. We write \( A_q(p) \) and \( B_q(p) \) for the corresponding elements of \( SL_{q+1} \mathbb{Z}_p \) if \( p \) is a prime or of \( SL_{q+1} \mathbb{Q} \) if \( p = 0 \). It is easy to prove

**Lemma 3.1.** (i) If \( q \) is odd, then \( A_q^2 = B_q^3 = -E \). Moreover the minimal polynomials of \( A_q \) and \( B_q \) are \( t^2 + 1 \) and \( t^3 + 1 \) respectively.

(ii) If \( q \) is even, then \( A_q^2 = B_q^3 = E \) and the minimal polynomials of \( A_q \) and \( B_q \) are \( t^2 - 1 \) and \( t^3 - 1 \) respectively.

**Corollary 3.2.** If \( q \) is odd, then both of \( A_q(p) + E \) and \( B_q(p) - E \) are invertible provided \( p \neq 2 \). In fact we have

\[
(A_q(p) + E)^{-1} = -\frac{1}{2}(A_q(p) - E) \quad \text{and} \quad (B_q(p) - E)^{-1} = -\frac{1}{2}(B_q^2(p) + B_q(p) + E).
\]
Now let $L_q(p)$ be either $L_q \otimes \mathbb{Z}_p$ if $p$ is a prime or $L_q \otimes \mathbb{Q}$ if $p=0$. $A_q(p)$ and $B_q(p)$ act on $L_q(p)$. We assume $q$ is even and define

$$L_q^-(p) = \{u \in L_q(p); A_q(p)u = -u\}$$
$$L_q^+(p) = \{u \in L_q(p); (B_q^2(p) + B_q(p) + E)u = 0\}.$$

**Lemma 3.2.** If $p \neq 2$ and $q=2r$, then

$$\dim L_q^- = \begin{cases} r+1 & r: \text{odd} \\ r & r: \text{even.} \end{cases}$$

**Proof.** It is easy to see that

$$\{x^r - y^r, x^{r-1}y + xy^{r-1}, x^{r-2}y^2 - x^2y^{r-2}, \ldots , x^{r+1}y^{r-1} - x^{r-1}y^{r+1}, x^r y^r\}$$

$(r: \text{odd})$ or

$$\{x^r - y^r, x^{r-1}y + xy^{r-1}, x^{r-2}y^2 - x^2y^{r-2}, \ldots , x^{r+1}y^{r-1} + x^{r-1}y^{r+1}\}$$

$(r: \text{even})$

forms a basis of $L_q^-$. 

Next we determine $\dim L_q^+$. We first consider the case $p=0$.

**Lemma 3.3.** Trace $B_q = 1, 1, 0, -1, -1, 0$ according as $q \equiv 0, 1, 2, 3, 4, 5 \pmod{6}$.

**Proof.** Observe that $B_q = (b_{ij}^q)$, where

$$b_{ij}^q = (-1)^{i+1} \binom{q-j+1}{i-1} (i, j = 1, \ldots , q+1).$$

(Here we understand that $\binom{s}{t} = 0$ if $t > s$). In other words the $j$-th column of $B_q$ consists of coefficients of the polynomial $(1-t)^{q-j+1}$. $B_q$ is naturally a minor matrix of $B_{q+1}$ and if we look at the "third quadrant infinite matrix" $B = \lim_{q \to \infty} B_q$ carefully, we find out that

Trace $B_q$ = the coefficient of $t^q$ in the power series

$$1 + t(1-t) + t^2(1-t)^2 + \cdots$$

But we have

$$\sum_{n=0}^{\infty} (t(1-t))^n = \frac{1}{1-t+t^2} = \frac{1}{(t-\omega)(t-\bar{\omega})}$$
where $\omega = \exp(2\pi i/6)$. From this we conclude

$$\text{Trace } B_q = \frac{1}{3}(\omega^q - \omega^{q+2} + \omega^{5q} - \omega^{5q+4}).$$

Then the desired result follows from a direct computation.

**Lemma 3.4.** If $q$ is even, then

$$\text{rank } (B_q^3 + B_q + E) = 2k + 1 \quad \text{for } q = 6k, 6k + 2 \text{ or } 6k + 4.$$

**Proof.** According to Lemma 3.1 (ii), the characteristic polynomial of $B_q$ is

$$(t - 1)^a(t^2 + t + 1)^b$$

for some $a, b \in \mathbb{N}$. But clearly

$$a + 2b = q + 1 \quad \text{and} \quad a - b = \text{Trace } B_q.$$

A simple computation using Lemma 3.3 implies the result.

Next we show that the above lemma also holds even if we replace $B_q$ by $B_q(p)$ ($p \neq 3$).

**Lemma 3.5.** Let $B_q = (b_{ij}^{(q)})$ and define $C_q = (c_{ij}^{(q)})$ by

$$c_{ij}^{(q)} = b_{q+2-i,q+2-j}^{(q)}.$$

Then we have $C_q = B_q^{-1}$. In other words, $B_q$ and $B_q^{-1}$ are mutually symmetric with respect to the "center" of them.

**Proof.** We use induction on $q$. If $q = 1$, then it is easy to check that $B_1C_1 = E$. We assume that $B_i C_i = E$ for $i = 1, \cdots, q - 1$. Now let $b_{i}^{(q)}$ be the $i$-th row of $B_q$ and let $c_{j}^{(q)}$ be the $j$-th column of $C_q$. We can write

$$B_q = \begin{pmatrix} * & B_{q-1} \\ (-1)^q & 0 \end{pmatrix}, \quad C_q = \begin{pmatrix} 0 & c_{q+1}^{(q)} \\ C_{q-1} & c_{q+1}^{(q)} \end{pmatrix}.$$

Hence by the induction assumption, it suffices to prove

$$b_{i}^{(q)} c_{q+1}^{(q)} = \delta_{i,q+1}$$

for $i = 1, \cdots, q+1$. Now it is easy to check that

$$\sum_{k=1}^{q} b_{k,j}^{(q)} = b_{i,j+1}^{(q)} = b_{i,j}^{(q-1)}$$
for any $i, j$ ($j \leq q$). Hence we have

$$b_i^{(q)} + b_{i+1}^{(q)} + \cdots + b_q^{(q)} = b_i^{(q-1)} 1 \quad (i = 1, \ldots, q)$$

and

$$b_1^{(q)} + b_2^{(q)} + \cdots + b_q^{(q)} = (0 1).$$

From this we can deduce

$$b_i^{(q)} = (b_i^{(q-1)} 1) - (b_{i-1}^{(q-1)} 1) \quad (i = 2, \ldots, q).$$

Similarly we have

$$c_{q+1}^{(q)} = c_q^{(q)} - \begin{pmatrix} c_{q}^{(q-1)} \\ 0 \end{pmatrix}.$$ 

Now it is easy to see that

$$b_1^{(q)} c_{q+1}^{(q)} = 0 \quad \text{and} \quad b_{q+1}^{(q)} c_{q+1}^{(q)} = 1.$$

On the other hand if $2 \leq i \leq q$, then

$$b_i^{(q)} c_{q+1}^{(q)} = b_i^{(q)} \left( c_q^{(q)} - \begin{pmatrix} c_{q}^{(q-1)} \\ 0 \end{pmatrix} \right)$$

$$= -b_i^{(q)} \begin{pmatrix} c_{q}^{(q-1)} \\ 0 \end{pmatrix}$$

$$= ((b_{i-1}^{(q-1)} 1) - (b_{i-2}^{(q-1)} 1)) \begin{pmatrix} c_{q}^{(q-1)} \\ 0 \end{pmatrix}$$

$$= 0$$

by the induction assumption (the first equality follows from the fact that $b_i^{(q)} c_{q}^{(q)} = b_i^{(q-1)} c_{q}^{(q-1)}$). This completes the proof.

**Lemma 3.6.** For each $q$, let $B_{q,s}^{(r)}$ ($1 \leq r \leq q+1, 1 \leq s \leq q+2-r$) be the matrix defined by

$$B_{q,s}^{(r)} = \begin{pmatrix} b_1^{(q)} & b_2^{(q)} & \cdots & b_q^{(q)} \\ b_{r+1}^{(q)} & b_{r+2}^{(q)} & \cdots & b_{r+s}^{(q)} \\ \vdots & \vdots & \ddots & \vdots \\ b_{q-s+1}^{(q)} & b_{q-s+2}^{(q)} & \cdots & b_{q+1}^{(q)} \end{pmatrix}.$$

Then we have $\det B_{q,s}^{(r)} = 1$ for all $r, s$.

**Proof.** First observe that $B_{q,s}^{(r)} = B_{q-s+1,1}^{(r)}$. Hence we may assume that $s=1$ and we simply write $B_q^{(r)}$ instead of $B_{q,s}^{(r)}$. If $r = q+1$, then $\det B_q^{(q+1)} = \det B_q = 1$. So assume that $r < q+1$. As in the proof of Lemma 3.5, we have

$$\sum_{k=1}^{q} b_k^{(q)} = b_i^{(q-1)}$$
for any $i, j$ $(j \leq q)$. Hence if we define $B_q^{(r)}$ to be the matrix obtained from $B_q^{(r)}$ by the following rule:

the $i$-th row of $B_q^{(r)} = \sum_{k=1}^{r} B_q^{(r)}$ (the $k$-th row of $B_q^{(r)})$,

then we have

$$B_q^{(r)} = B_q^{(r-1)}$$

and clearly $\det B_q^{(r)} = \det B_q^{(r)} = \det B_q^{(r-1)}$. Hence inductively we have

$$\det B_q^{(r)} = \det B_q^{(r-1)} = \cdots = \det B_q^{(r-

This completes the proof.

**Lemma 3.7.** Assume that $q$ is even and $p \neq 3$. Then we have

$$\text{rank } (B_q^{(p)} + B_q(p) + E) = 2k + 1$$

if $q = 6k, 6k + 2$ or $6k + 4$.

**Proof.** Clearly we have

$$\text{rank } (B_q^{(p)} + B_q(p) + E) \leq \text{rank } (B_q^{(p)} + B_q + E).$$

Hence, in view of Lemma 3.4, we have only to show the existence of a minor determinant of $(B_q^{(p)} + B_q + E)$ of degree $2k + 1$ (for $q = 6k, 6k + 2$ or $6k + 4$), which is a power of 3. Now observe that if $i + j > q + 2$, then

$$b_{ij}^{(q)} = 0.$$ 

We are assuming that $q$ is even so that $B_q^{(p)} = B_q^{(p)}$ (see Lemma 3.1 (ii)). Hence by Lemma 3.5, if $i + j < q + 2$, then

$$c_{ij}^{(q)} = 0.$$ 

Therefore the $(i, j)$-component of $B_q^{(p)} + B_q + E$ coincides with that of $B_q$ if $(i, j)$ belongs to the set

$$K = \{(i, j); i + j < q + 2 \text{ and } j > i\}.$$ 

If $q = 6k + 2$ or $6k + 4$, then it is easy to see that the minor matrix $B_q^{(2k+1)}$ of $B_q$ is completely contained in the region of $B_q$ corresponding to $K$ so that $B_q^{(2k+1)}$ can also be considered to be a minor matrix of $B_q^{2} + B_q + E$. But we have

$$\det B_q^{(2k+1)} = 1$$

by Lemma 3.6. Now if $q = 6k$, then the bottom elements of the first
and the last columns of $B_{q,2k+1}^{(2k+1)}$ are not contained in the region of $B_q$ corresponding to $K$. If we denote $D_{q,2k+1}^{(2k+1)} = (d_{ij})$ for the corresponding minor matrix of $B_q^2 + B_q + E$, then all the entries of $D_{q,2k+1}^{(2k+1)}$ coincide with those of $B_{q,2k+1}^{(2k+1)}$ except the following two components:

$$d_{2k+1,1} = b_{2k+1,1,2k+1}^{(q)} + 1$$
$$d_{2k+1,2k+1} = b_{2k+1,1,4k+1}^{(q)} + 1 = 2.$$

Here we have used Lemma 3.5 to deduce the second equality. Then by Lemma 3.6, we conclude that

$$\det D_{q,2k+1}^{(2k+1)} = 3.$$

This completes the proof.

§ 4. $H^*(SL_2Z; k[x, y])$

In this section we compute $H^*(SL_2Z; k[x, y])$ for $k = \mathbb{Q}$ or $\mathbb{Z}_p$ ($p \neq 2, 3$).

Recall that we denote $L_q(p)$ for $L_q \otimes \mathbb{Z}_p$ if $p$ is a prime or for $L_q \otimes \mathbb{Q}$ if $p = 0$. Now let $Z^1(SL_2Z; L_q(p))$ be the set of all 1-cocycles of $SL_2Z$ with values in $L_q(p)$, namely it is the set of all crossed homomorphisms $f: SL_2Z \rightarrow L_q(p)$.

Since $SL_2Z$ is generated by two elements $\alpha$ and $\beta$, a crossed homomorphism $f: SL_2Z \rightarrow L_q(p)$ is completely determined by two values $f(\alpha)$ and $f(\beta)$. Moreover the two relations $\alpha^2 = 1$ and $\alpha^3 = \beta^3$ imply

$$(A_q^2(p) + A_q(p) + A_q(p) + E)f(\alpha) = 0$$
$$(A_q(p) + E)f(\alpha) = (B_q^2(p) + B_q(p) + E)f(\beta).$$

Conversely if two elements $f(\alpha)$ and $f(\beta)$ of $L_q(p)$ satisfy the above two equations, then there is defined the associated crossed homomorphism $f: SL_2Z \rightarrow L_q(p)$ with prescribed values at $\alpha, \beta$. If we combine the above argument with Lemma 3.1, we can conclude

**Lemma 4.1.** (i) If $q$ is odd, then

$$Z^1(SL_2Z; L_q(p)) = \{(u, v) \in L_q(p) \times L_q(p); (A_q(p) + E)u = (B_q^2(p) + B_q(p) + E)v\}.$$

(ii) If $q$ is even, then

$$Z^1(SL_2Z; L_q(p)) = \{(u, v) \in L_q(p) \times L_q(p); (A_q(p) + E)u = 0, (B_q^2(p) + B_q(p) + E)v = 0\}.$$
Now let
\[ \delta : L_q(p) \to \mathbb{Z}^1(SL_2 \mathbb{Z}; L_q(p)) \]
be the homomorphism defined by
\[ \delta(u)(r) = (r^{-1})u \quad (u \in L_q(p), \ r \in SL_2 \mathbb{Z}). \]
Then by the definition of cohomology of groups, we have
\[ H^0(SL_2 \mathbb{Z}; L_q(p)) = \text{Ker} \ \delta \]
\[ = \{ u \in L_q(p); A_q(p)u - u = B_q(p)u - u = 0 \} \quad \text{and} \]
\[ H^1(SL_2 \mathbb{Z}; L_q(p)) = \text{Cok} \ \delta. \]

**Proposition 4.2.** \( H^0(SL_2 \mathbb{Z}; \mathbb{Q}[x, y]) = \mathbb{Q}. \)

**Proof.** It suffices to prove that the only polynomials in \( \mathbb{Q}[x, y] \) which are left invariant under the action of \( SL_2 \mathbb{Z} \) are constants. This follows from a direct computation details of which are omitted.

**Remark 4.3.** According to a classical result of Dickson [2] (see also Tezuka [8]), the subring of \( \mathbb{Z}_p[x, y] \) consisting of those elements which are invariant by the action of \( SL_2 \mathbb{Z} \), namely \( H^0(SL_2 \mathbb{Z}; \mathbb{Z}_p[x, y]) \), is the polynomial ring generated by the following two elements
\[ x^p y - xy^p \quad \text{and} \quad \frac{x^{p^2} y - xy^{p^2}}{x^py - xy^p} = y^p(x^{p-1}) + (xy^{p-1})^{p-1}. \]
Hence if we write \( d_q(p) \) for \( \dim H^0(SL_2 \mathbb{Z}; L_q(p)) \), then we have
\[ \sum_{q=0}^{\infty} d_q(p)t^q = \frac{1}{(1 - t^{p+1})(1 - t^{p(p-1)})}. \]

**Proposition 4.4.** If \( q \) is odd and \( p \neq 2 \), then
\[ H^0(SL_2 \mathbb{Z}; L_q(p)) = H^1(SL_2 \mathbb{Z}; L_q(p)) = 0. \]

**Proof.** According to Corollary 3.2, \( B_q(p) - E \) is invertible and so the homomorphism \( \delta : L_q(p) \to \mathbb{Z}^1(SL_2 \mathbb{Z}; L_q(p)) \) is injective. Hence \( H^0(SL_2 \mathbb{Z}; L_q(p)) = 0. \) Next let \( (u, v) \in \mathbb{Z}^1(SL_2 \mathbb{Z}; L_q(p)) \) be any element (see Lemma 4.1 (i)) so that
\[ (A_q(p) + E)u = (B_q^2(p) + B_q(p) + E)v. \]

\[ ^{(*)} \] I owe this remark to M. Tezuka. I would like to express my hearty thanks to him.
By Corollary 3.2, we have
\[ u = -\frac{1}{2} (A_q(p) - E)(B^2_q(p) + B_q(p) + E)v. \]

Since \( B_q(p) - E \) is invertible, there is an element \( w \in L_q(p) \) such that \( v = (B_q(p) - E)w \). Then
\[ u = (A_q(p) - E)w. \]

Therefore
\[ (u, v) = ((A_q(p) - E)w, (B_q(p) - E)w) = \delta w \]
and hence \( H^1(SL_2Z; L_q(p)) = 0 \). This completes the proof.

Henceforth we assume that \( q \) is even and consider \( H^1(SL_2Z; L_q(p)) \). According to Lemma 4.1 (ii), we have an identification
\[ Z^1(SL_2Z; L_q(p)) = L_q^-(p) \oplus L_q'(p) \quad (p \neq 2) \]
where \( L_q^-(p) \) and \( L_q'(p) \) have been defined in Section 3.

**Proposition 4.5.** If \( q \) is even, then
\[
\dim H^1(SL_2Z; L_q(0)) = \begin{cases} 
2m - 1 & q = 12m \\
2m + 1 & q = 12m + 2, 12m + 4, 12m + 6, \text{ or } 12m + 8 \\
2m + 3 & q = 12m + 10.
\end{cases}
\]

**Proof.** We know that the homomorphism \( \delta; L_q(0) \rightarrow Z^1(SL_2Z; L_q(0)) \) is injective (Proposition 4.2). Hence we have
\[
\dim H^1(SL_2Z; L_q(0)) = \dim Z^1(SL_2Z; L_q(0)) - (q + 1)
\]
\[ = \dim L_q^-(0) + \dim L_q'(0) - (q + 1). \]
Then the result follows from Lemma 3.2 and Lemma 3.4.

**Proposition 4.6.** Assume \( q \) is even and let \( d_q(p) = \dim H^0(SL_2Z; L_q(p)) \) (see Remark 4.3). Then for \( p \neq 2, 3 \), we have
\[
\dim H^1(SL_2Z; L_q(p)) = \dim H^1(SL_2Z; L_q(0)) + d_q(p).
\]

**Proof.** By a similar argument as in the proof of Proposition 4.5, we have
\[
\dim H^1(SL_2Z; L_q(p)) = \dim L_q^-(p) + \dim L_q'(p) - (q + 1) + d_q(p).
\]
Characteristic Classes of $T^2$-bundles

Then the result follows because we have

$$\dim L_\xi(p) = \dim L_\xi(0) \quad (p \neq 2)$$

by Lemma 3.2 and also we have

$$\dim L'_\xi(p) = \dim L'_\xi(0) \quad (p \neq 3)$$

by Lemma 3.4 and Lemma 3.7. This completes the proof.

§ 5. Proof of Theorems

Theorem 1.1 follows from Corollary 2.2, Proposition 4.2 and Proposition 4.5. Also, if $p \neq 2, 3$, Corollary 2.2, Proposition 4.4 and Proposition 4.6 imply

$$\dim H^*(B \text{Diff}_+ T^2; \mathbb{Z}_p) = \begin{cases} 
\begin{aligned}
&d_q(p) \\
&\dim H^*(B \text{Diff}_+ T^2; \mathbb{Q}) + d_q(p)
\end{aligned}
\end{cases} \quad \begin{aligned}
n &= 2q \quad (q: \text{even}) \\
n &= 2q + 1 \quad (q: \text{even}) \\
\end{aligned}$$

Hence if $n \equiv 2, 3 \pmod 4$, then

$$H_n(B \text{Diff}_+ T^2; \mathbb{Z}) = 0 \quad \text{mod 2, 3 torsions}$$

by the universal coefficient theorem. Similarly it is easy to deduce that $H_n(B \text{Diff}_+ T^2; \mathbb{Z})$ has no $p$-torsions ($p \neq 2, 3$) if $n \equiv 1 \pmod 4$. This completes the proof of Theorem 1.2.

Remark 5.1. $H_*(B \text{Diff}_+ T^2; \mathbb{Z})$ has actually 2 and 3 torsions. This follows from the following argument. The projection $B \text{Diff}_+ T^2 \to K(SL_2 \mathbb{Z}, 1)$ has a right inverse because $SL_2 \mathbb{Z}$ can be naturally considered as a subgroup of $\text{Diff}_+ T^2$. Hence the homology

$$H_*(SL_2 \mathbb{Z}; \mathbb{Z}) \cong H_*(K(\mathbb{Z}_{12}, 1); \mathbb{Z})$$

embeds into $H_*(B \text{Diff}_+ T^2; \mathbb{Z})$ as a direct summand. It is easy to check that $H_1(B \text{Diff}_+ T^2; \mathbb{Z}) \cong \mathbb{Z}_{12}$ and $H_*(B \text{Diff}_+ T^2; \mathbb{Z}) = 0$.

Remark 5.2. By Theorem 1.1 and Theorem 1.2, we have an isomorphism

$$H^{4k}(B \text{Diff}_+ T^2; \mathbb{Z}_p) \cong \text{Hom} (H_{4k}(B \text{Diff}_+ T^2; \mathbb{Z}), \mathbb{Z}_p) \quad (p \neq 2, 3).$$

On the other hand we have

$$H^{4k}(B \text{Diff}_+ T^2; \mathbb{Z}_p) \cong L_{2k}(p)^{SL_2 \mathbb{Z}}$$
by Corollary 2.2, where the right hand side denotes the subspace of $L_{2k}(p)$ consisting of those elements which are left invariant by the action of $SL_2\mathbb{Z}$. Then in view of Remark 4.3, we can conclude that the $p$-primary part of $H_{4k}(B\text{Diff}_+, T^2; \mathbb{Z})$ is non-trivial provided $2k$ can be expressed as a linear combination of $p+1$ and $p(p-1)$ with coefficients in non-negative integers. Also it can be shown that mod 2 and 3 torsions we have an isomorphism

$$H_{4k}(B\text{Diff}_+, T^2; \mathbb{Z}) \cong L_{2k}/K_{2k}$$

where $K_{2k}$ denotes the submodule of $L_{2k}$ generated by elements $\tilde{r}(u)-u$ ($u \in L_{2k}$, $\tilde{r} \in SL_2\mathbb{Z}$).

**Example 5.3.** We construct an element of $H_4(B\text{Diff}_+, T^2; \mathbb{Z})$ which has infinite order. First it can be shown by a direct computation that the crossed homomorphism

$$f: SL_2\mathbb{Z} \rightarrow L_2(0)$$

given by $f(\alpha)=x^2 - y^2$ and $f(\beta)=0$ represents a non-zero element of $H^1(SL_2\mathbb{Z}; L_2(0)) \cong \mathbb{Q}$ (see Proposition 4.5). We write $[f] \in H^2(B\text{Diff}_+, T^2; \mathbb{Q})$ for the corresponding element (see Corollary 2.2). Now let $\eta$ be the canonical line bundle over $CP^2$ and let $T^2 \rightarrow E(k, l) \rightarrow CP^2$ be the $T^2$-bundle associated to the complex 2-plane bundle $\eta^k \oplus \eta^l$ on $CP^2$, $(k, l \in \mathbb{Z})$. Let $T^2 \rightarrow E'(k, l) \rightarrow CP^1$ be the restriction of $E(k, l)$ to $CP^1 \subset CP^2$. Then we can write

$$E'(k, l) = D^2 \times S^1 \times S^1 \bigcup_{g_{k, l}} D^3 \times S^1 \times S^1$$

where the pasting map $g_{k, l}: \partial D^2 \times S^1 \times S^1 \rightarrow \partial D^2 \times S^1 \times S^1$ is given by

$$g_{k, l}(z_1, z_2, z_3) = (z_1^{-k}, z_1^k z_2, z_1^l z_3)$$

($z_1, z_2, z_3 \in S^1$). Now for an element $\tilde{r} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2\mathbb{Z}$, let $h_\tilde{r}: D^2 \times S^1 \times S^1 \rightarrow D^2 \times S^1 \times S^1$ be the diffeomorphism defined by

$$h_\tilde{r}(z_1, z_2, z_3) = (z_1, z_1^a z_2^c, z_1^b z_3^d)$$

($z_1, z_2, z_3 \in S^1$). It is easy to show that if two relations:

$$ak + bl = k \quad \text{and} \quad ck + dl = l$$

are satisfied, then $h_\tilde{r}$ extends to a diffeomorphism $h'_\tilde{r}: E'(k, l) \rightarrow E'(k, l)$ which is an automorphism as a $T^2$-bundle. Then since $\pi_1(\text{Diff}_+, T^2)=0$, we can extend $h'_\tilde{r}$ to an automorphism $H_\tilde{r}: E(k, l) \rightarrow E(k, l)$. $H_\tilde{r}$ is nothing but the automorphism of $E(k, l)$ as a principal $T^2$-bundle defined by the
Characteristic Classes of $T^2$-bundles

automorphism of $T^2$ given by $\gamma$. Let $M_\gamma(k, l)$ be the mapping torus of $H_\gamma$. The natural projection

$$M_\gamma(k, l) \to S^1 \times CP^2$$

has the structure of a $T^2$-bundle. Clearly the classifying map of this $T^2$-bundle is given by

$$CP^2 \to S^1 \times CP^2 \to S^1$$

$$i_0 \downarrow \quad i \downarrow \quad i \downarrow$$

$$B \text{Diff}_0 T^2 \to B \text{Diff}_+ T^2 \to K(SL_2 Z, 1)$$

where $i_0$ is characterized by the induced map $i_0^*: H^2(B \text{Diff}_0 T^2; Z) \to H^2(CP^2; Z)$ which is given by $i_0^*(x)=k \beta$, $i_0^*(y)=l \alpha (\epsilon \in H^2(CP^2; Z)$ is the first Chern class of $\gamma)$ and the map $i$ represents $\gamma^{-1} \in \pi_1(K(SL_2 Z, 1))=SL_2 Z$. Therefore we conclude that

$$\langle [S^1 \times CP^2], i^*([f]) \rangle = i_0^*(f(\gamma^{-1})) \in H^4(CP^2; Q) \cong Q.$$ 

If we choose $\gamma = \begin{pmatrix} 2 & -1 \\ 1 & 0 \end{pmatrix}$ and $k = l = 1$, then $\gamma = \beta^{-1} \alpha \beta^{-1}$ so that $f(\gamma^{-1})=y^2 - 2xy$ and hence $i_0^*(f(\gamma^{-1}))=-\beta^2$. This proves that the corresponding $T^2$-bundle represents a non-zero element of $H_5(B \text{Diff}_+ T^2; Q)$. Similarly we can construct non-zero elements of $H_{4k+1}(B \text{Diff}_+ T^2; Q) (k > 1)$ explicitly, but we stop here.
