# SIMULATION OF BSDES BY WIENER CHAOS EXPANSION 

By Philippe Briand and Céline Labart<br>Université de Savoie

#### Abstract

We present an algorithm to solve BSDEs based on Wiener chaos expansion and Picard's iterations. We get a forward scheme where the conditional expectations are easily computed thanks to chaos decomposition formulas. We use the Malliavin derivative to compute $Z$. Concerning the error, we derive explicit bounds with respect to the number of chaos and the discretization time step. We also present numerical experiments. We obtain very encouraging results in terms of speed and accuracy.

1. Introduction. In this paper, we are interested in the numerical approximation of solutions $(Y, Z)$ to backward stochastic differential equations (BSDEs for short in the sequel). BSDEs were introduced by Bismut in [5] in the linear case, whereas the nonlinear case was considered later by Pardoux and Peng in [21]. A BSDE is an equation of the following form:

$$
\begin{equation*}
Y_{t}=\xi+\int_{t}^{T} f\left(s, Y_{s}, Z_{s}\right) d s-\int_{t}^{T} Z_{s} \cdot d B_{s}, \quad 0 \leq t \leq T \tag{1.1}
\end{equation*}
$$

where $B$ is a $d$-dimensional standard Brownian motion, the terminal condition $\xi$ is a real-valued $\mathcal{F}_{T}$-measurable random variable where $\left\{\mathcal{F}_{t}\right\}_{0 \leq t \leq T}$ stands for the augmented filtration of the Brownian motion $B$ and the generator $f$ is a map from $[0, T] \times \mathbb{R} \times \mathbb{R}^{d}$ into $\mathbb{R}$. A solution to this equation is a pair of processes $\left\{\left(Y_{t}, Z_{t}\right)\right\}_{0 \leq t \leq T}$ which is required to be adapted to the filtration $\left\{\mathcal{F}_{t}\right\}_{0 \leq t \leq T}$. We will assume the conditions of Pardoux and Peng to ensure existence and uniqueness of solutions.

Our main objective in this study is the numerical approximation of the solution ( $Y, Z$ ) to $\operatorname{BSDE}$ (1.1) (even though there exists a large literature on this subject). The first two contributions to this topic are due to Chevance [9], who considered generators independent of $Z$ and Bally [1], who used a random time mesh. Ma and Yong [18] proposed numerical schemes based on the link between Markovian BSDEs and semilinear partial differential equations (PDEs). Another approach, based on Donsker's theorem and close to [9], was proposed by Coquet, Mackevicius and Mémin [10] in the case of a generator $f$ independent of $Z$; the general case was treated by Briand, Delyon and Mémin in [7], who later extended it to a

[^0]more general framework [8], including the case of a "stepwise constant Brownian motion." This extension led to the formulas
$$
Y_{t}=\mathbb{E}\left(Y_{t+h} \mid \mathcal{F}_{t}\right)+h f\left(t, Y_{t}, Z_{t}\right), \quad Z_{t}=h^{-1} \mathbb{E}\left(Y_{t+h}\left(B_{t+h}-B_{t}\right) \mid \mathcal{F}_{t}\right)
$$
known as the dynamic programming algorithm. Even though the convergence was proved in the case of path-dependent terminal condition $\xi$, the rate of convergence was left as an open question in [8]. This problem was solved by Zhang [23] and Bouchard and Touzi [6] in the case of Markovian BSDE, namely in the case of a terminal condition $\xi=g\left(X_{T}\right)$ where $X$ is the solution to a stochastic differential equation; in [23], the author considers the path-dependent case as well. Their result was generalized by Gobet and Labart [13] and also by Gobet and Makhlouf [16].

From a numerical point of view, the main difficulty in solving BSDEs is to efficiently compute conditional expectations. Several approaches have been proposed using various tools: the Malliavin calculus [6], regression methods [15, 17] and quantization technics [2].

Finally, let us mention that there exist some works dealing with the discretization of solutions to BSDEs in a more general framework: forward-backward SDEs [11] and quadratic BSDEs [22].

Let us now describe briefly the main points of our approach in the case of a real-valued Brownian motion. Already used in several quoted papers (see also [3, $4,14]$ ), our starting point is the use of Picard's iterations, $\left(Y^{0}, Z^{0}\right)=(0,0)$ and for $q \in \mathbb{N}$,

$$
Y_{t}^{q+1}=\xi+\int_{t}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s-\int_{t}^{T} Z_{s}^{q+1} \cdot d B_{s}, \quad 0 \leq t \leq T
$$

It is well known that the sequence $\left(Y^{q}, Z^{q}\right)$ converges exponentially fast toward the solution $(Y, Z)$ to BSDE (1.1). We write this Picard scheme in a forward way,

$$
\begin{aligned}
Y_{t}^{q+1} & =\mathbb{E}\left(\xi+\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s \mid \mathcal{F}_{t}\right)-\int_{0}^{t} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s \\
Z_{t}^{q+1} & =D_{t} Y_{t}^{q+1}=D_{t} \mathbb{E}\left(\xi+\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s \mid \mathcal{F}_{t}\right)
\end{aligned}
$$

where $D_{t} X$ stands for the Malliavin derivative of the random variable $X$.
In order to compute the previous conditional expectation, we use a Wiener chaos expansion of the random variable

$$
F^{q}=\xi+\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s
$$

More precisely, we use the following orthogonal decomposition of the random variable $F^{q}$ :

$$
F^{q}=\mathbb{E}\left[F^{q}\right]+\sum_{k \geq 1} \sum_{|n|=k} d_{k}^{n} \prod_{i \geq 1} K_{n_{i}}\left(\int_{0}^{T} g_{i}(s) d B_{s}\right),
$$

where $K_{l}$ denotes the Hermite polynomial of degree $l,\left(g_{i}\right)_{i \geq 1}$ is an orthonormal basis of $\mathrm{L}^{2}(0, T)$ and, if $n=\left(n_{i}\right)_{i \geq 1}$ is a sequence of integers, $|n|=\sum_{i \geq 1} n_{i}$. $\left(d_{k}^{n}\right)_{k \geq 1,|n|=k}$ is the sequence of coefficients ensuing from the decomposition of $F^{q}$. Of course, from a practical point of view, we only keep a finite number of terms in this expansion:

- we work with a finite number of chaos, $p$;
- we choose a finite number of functions $g_{1}, \ldots, g_{N}$.

This leads to the following approximation with $n=\left(n_{1}, \ldots, n_{N}\right)$ :

$$
F^{q} \simeq \mathbb{E}\left[F^{q}\right]+\sum_{1 \leq k \leq p} \sum_{|n|=k} d_{k}^{n} \prod_{1 \leq i \leq N} K_{n_{i}}\left(\int_{0}^{T} g_{i}(s) d B_{s}\right) .
$$

One of the key points in using such a decomposition is that, for choices of simple functions $g_{1}, \ldots, g_{N}$, there exist explicit formulas for both

$$
\begin{equation*}
\mathbb{E}\left(F^{q} \mid \mathcal{F}_{t}\right) \quad \text { and } \quad Z_{t}^{q+1}=D_{t} \mathbb{E}\left(F^{q} \mid \mathcal{F}_{t}\right) \tag{1.2}
\end{equation*}
$$

this plays a crucial role in our algorithm. Using these formulas and starting from $M$ trajectories of the underlying Brownian motion, we are able to construct $M$ trajectories of the solution $(Y, Z)$ to the BSDE.

In the following, the functions $g_{i}$ are chosen as step functions:

$$
g_{i}=\mathbf{1}_{\left[\bar{t}_{i-1}, \bar{t}_{i}\right]}(t) / \sqrt{h}, \quad i=1, \ldots, N, \text { where } \bar{t}_{i}:=i h, h=\frac{T}{N}
$$

and the previous formulas are really simple; see (2.8)-(2.9) and Proposition 2.7. Eventually, the main advantage of this method is that only one decomposition has to be computed per Picard iteration: the decomposition of $F^{q}$. Therein lies the main difference between our approach and the approach based on regression technique developed by Bender and Denk in [3]. In their paper, for a given Picard iteration $q$ and for each time $t_{i}$ of the mesh grid, two projections have to be computed, one for $Y_{t_{i}}^{q}$ and one for $Z_{t_{i}}^{q}$. The second difference comes from the way of computing $Z^{q}$. In our method, once the decomposition of $F^{q}$ is computed, $Z^{q}$ is given explicitly as the Malliavin derivative of $Y^{q}$. Let us also point out that our algorithm can handle fully path dependent terminal conditions.

The rest of the paper is organized as follows. Section 2 contains the notation and the preliminary results, Section 3 describes precisely the algorithm, Section 4 is devoted to the study of the convergence of the algorithm and finally Section 5 contains some numerical experiments. Some technical proofs are postponed to the Appendix.

## 2. Preliminaries.

2.1. Definitions and notation. Given a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and an $\mathbb{R}^{d^{-}}$ valued Brownian motion $B$, we consider:

- $\left\{\left(\mathcal{F}_{t}\right) ; t \in[0, T]\right\}$, the filtration generated by the Brownian motion $B$ and augmented.
- $\mathrm{L}^{p}\left(\mathcal{F}_{T}\right):=\mathrm{L}^{p}\left(\Omega, \mathcal{F}_{T}, \mathbb{P}\right), p \in \mathbb{N}^{*}$, the space of all $\mathcal{F}_{T}$-measurable random variables (r.v. in the following) $X: \Omega \longmapsto \mathbb{R}^{d}$ satisfying $\|X\|_{p}^{p}:=\mathbb{E}\left(|X|^{p}\right)<\infty$.
- $\mathbb{E}_{t}(X)$ denotes $\mathbb{E}\left(X \mid \mathcal{F}_{t}\right)$ for any $X$ in $\mathrm{L}^{1}\left(\mathcal{F}_{T}\right)$.
- $\mathrm{S}_{T}^{p}\left(\mathbb{R}^{d}\right), p \in \mathbb{N}, p \geq 2$, the space of all càdlàg predictable processes $\phi: \Omega \times$ $[0, T] \longmapsto \mathbb{R}^{d}$ such that $\|\phi\|_{\mathrm{S}^{p}}^{p}=\mathbb{E}\left(\sup _{t \in[0, T]}\left|\phi_{t}\right|^{p}\right)<\infty$.
- $\mathrm{H}_{T}^{p}\left(\mathbb{R}^{d}\right), p \in \mathbb{N}, p \geq 2$, the space of all predictable processes $\phi: \Omega \times[0, T] \longmapsto$ $\mathbb{R}^{d}$ such that $\|\phi\|_{\mathrm{H}_{T}^{p}}^{p}=\mathbb{E} \int_{0}^{T}\left|\phi_{t}\right|^{p} d t<\infty$.
- $\mathrm{L}^{2}(0, T)$, the space of all square integrable functions on $[0, T]$.
- $C^{k, l}$, the set of continuously differentiable functions $\phi:(t, x) \in[0, T] \times \mathbb{R}^{d}$ with continuous derivatives w.r.t. $t$ (resp., w.r.t. $x$ ) up to order $k$ (resp., up to order $l$ ).
- $C_{b}^{k, l}$, the set of continuously differentiable functions $\phi:(t, x) \in[0, T] \times \mathbb{R}^{d}$ with continuous and uniformly bounded derivatives w.r.t. $t$ (resp., w.r.t. $x$ ) up to order $k$ (resp., up to order $l$ ). The function $\phi$ is also bounded.
- $\left\|\partial_{\mathrm{sp}}^{j} f\right\|_{\infty}^{2}$, the norm of the derivatives of $f\left([0, T] \times \mathbb{R}^{d}, \mathbb{R}\right)$ w.r.t. all the space variables $x$ which sum equals $j:\left\|\partial_{\text {sp }}^{j} f\right\|_{\infty}^{2}:=\sum_{|k|=j}\left\|\partial_{x_{1}}^{k_{1}} \cdots \partial_{x_{d}}^{k_{d}} f\right\|_{\infty}^{2}$, where $|k|=k_{1}+\cdots+k_{d}$.
- $C_{p}^{\infty}$, the set of smooth functions $f: \mathbb{R}^{n} \longmapsto \mathbb{R}$ with partial derivatives of polynomial growth.
- $\|(\cdot, \cdot)\|_{\mathrm{L}^{p}}^{p}, p \in \mathbb{N}, p \geq 2$, the norm on the space $\mathrm{S}_{T}^{p}(\mathbb{R}) \times \mathrm{H}_{T}^{p}\left(\mathbb{R}^{d}\right)$ defined by

$$
\begin{equation*}
\|(Y, Z)\|_{L^{p}}^{p}:=\mathbb{E}\left(\sup _{t \in[0, T]}\left|Y_{t}\right|^{p}\right)+\int_{0}^{T} \mathbb{E}\left(\left|Z_{t}\right|^{p}\right) d t \tag{2.1}
\end{equation*}
$$

We also recall some useful definitions related to Malliavin calculus. We use the notation of [19].

- $\mathcal{S}$ denotes the class of random variables of the form $F=f\left(W\left(h_{1}\right), \ldots, W\left(h_{n}\right)\right)$, where $f \in C_{p}^{\infty}\left(\mathbb{R}^{n \times d}, \mathbb{R}\right)$, for all $j \leq n h_{j}=\left(h_{j}^{1}, \ldots, h_{j}^{d}\right) \in \mathrm{L}^{2}\left([0, T] ; \mathbb{R}^{d}\right)$ and for all $i \leq d W^{i}\left(h_{j}^{i}\right)=\int_{0}^{T} h_{j}^{i}(t) d W_{t}^{i}$.
- $\mathbb{D}^{r, 2}$ denotes the closure of $\mathcal{S}$ w.r.t. the following norm on $\mathcal{S}$

$$
\|F\|_{\mathbb{D}^{r}, 2}^{2}:=\mathbb{E}|F|^{2}+\sum_{q=1}^{r} \sum_{|\alpha|_{1}=q} \mathbb{E}\left(\int_{0}^{T} \cdots \int_{0}^{T}\left|D_{\left(t_{1}, \ldots, t_{q}\right)}^{\alpha} F\right|^{2} d t_{1} \cdots d t_{q}\right),
$$

where $\alpha$ is a multi-index $\left(\alpha_{1}, \ldots, \alpha_{q}\right) \in\{1, \ldots, d\}^{q}|\alpha|_{1}:=\sum_{i=1}^{q} \alpha_{i}=q$, and $D^{\alpha}$ represents the multi-index Malliavin derivative operator. We recall $\mathbb{D}^{\infty, 2}=$ $\bigcap_{r=1}^{\infty} \mathbb{D}^{r, 2}$.

REMARK 2.1. When $d=1,\|F\|_{\mathbb{D}^{r}, 2}^{2}:=\mathbb{E}|F|^{2}+\sum_{q=1}^{r} \mathbb{E}\left(\int_{0}^{T} \cdots\right.$ $\left.\int_{0}^{T}\left|D_{\left(t_{1}, \ldots, t_{q}\right)}^{(q)} F\right|^{2} d t_{1} \cdots d t_{q}\right)=\mathbb{E}|F|^{2}+\sum_{q=1}^{r}\left\|D^{(q)} F\right\|_{\mathrm{L}^{2}\left(\Omega \times[0, T]^{q}\right)}^{2}$.

Let $m \in \mathbb{N}^{*}$ and $j \in \mathbb{N}, j \geq 2$. We also introduce the following notation:

- $\mathcal{D}^{m, j}$ denotes the space of all $\mathcal{F}_{T}$-measurable r.v. such that

$$
\|F\|_{m, j}^{j}:=\sum_{1 \leq l \leq m} \sum_{|\alpha|_{1}=l} \sup _{t_{1} \leq \cdots \leq t_{l}} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{\alpha} F\right|^{j}\right]<\infty
$$

where $\sup _{t_{1} \leq \cdots \leq t_{l}}$ means $\sup _{\left(t_{1}, \ldots, t_{l}\right): t_{1} \leq \cdots \leq t_{l}}$.

- $\mathcal{S}^{m, j}$ denotes the space of all couple of processes $(Y, Z)$ belonging to $\mathrm{S}_{T}^{j}(\mathbb{R}) \times$ $\mathrm{H}_{T}^{j}\left(\mathbb{R}^{d}\right)$ and such that

$$
\|(Y, Z)\|_{m, j}^{j}:=\sum_{1 \leq l \leq m} \sum_{|\alpha|_{1}=l} \sup _{t_{1} \leq \cdots \leq t_{l}}\left\|\left(D_{t_{1}, \ldots, t_{l}}^{\alpha} Y, D_{t_{1}, \ldots, t_{l}}^{\alpha} Z\right)\right\|_{L^{j}}^{j}<\infty .
$$

We recall

$$
\begin{aligned}
\|(Y, Z)\|_{m, j}^{j}=\sum_{1 \leq l \leq m} \sum_{|\alpha|_{1}=l} \sup _{t_{1} \leq \cdots \leq t_{l}} & \left\{\mathbb{E}\left[\sup _{t_{l} \leq r \leq T}\left|D_{t_{1}, \ldots, t_{l}}^{\alpha} Y_{r}\right|^{j}\right]\right. \\
& \left.+\int_{t_{l}}^{T} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{\alpha} Z_{r}\right|^{j}\right] d r\right\}
\end{aligned}
$$

We also denote $\mathcal{S}^{m, \infty}:=\bigcap_{j \geq 2} \mathcal{S}^{m, j}$.

### 2.2. Wiener chaos expansion.

2.2.1. Notation and useful results. We refer to [19] for more details on this section. Let us briefly recall the Wiener chaos expansion in the simple case of a real-valued Brownian motion. It is well known that every random variable $F \in$ $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right)$ has an expansion of the following form:

$$
\begin{align*}
F= & \mathbb{E}[F]+\int_{0}^{T} u_{1}\left(s_{1}\right) d B_{s_{1}} \\
& +\int_{0}^{T} \int_{0}^{s_{2}} u_{2}\left(s_{2}, s_{1}\right) d B_{s_{1}} d B_{s_{2}}+\cdots  \tag{2.2}\\
& +\int_{0}^{T} \int_{0}^{s_{n}} \cdots \int_{0}^{s_{2}} u_{n}\left(s_{n}, \ldots, s_{1}\right) d B_{s_{1}} \cdots d B_{s_{n}}+\cdots,
\end{align*}
$$

where the functions ( $u_{n}, n \geq 1$ ) are deterministic functions. There is an ambiguity for the definition of these functions $u_{n}$. We adopt in this paper the following point of view: the function $u_{n}$ is defined on the simplex

$$
\mathcal{S}_{n}(T):=\left\{\left(s_{1}, \ldots, s_{n}\right) \in[0, T]^{n}: 0<s_{1}<\cdots<s_{n}<T\right\} .
$$

We define the iterated integral for a deterministic function $f \in \mathrm{~L}^{2}\left(\mathcal{S}_{n}(T)\right)$ as

$$
J_{n}(f):=\int_{0}^{T} \int_{0}^{s_{n}} \cdots \int_{0}^{s_{2}} f\left(s_{n}, \ldots, s_{1}\right) d B_{s_{1}} \cdots d B_{s_{n}}
$$

Due to the Itô isometry, $\left\|J_{n}(f)\right\|^{2}=\|f\|_{\mathrm{L}^{2}\left(\mathcal{S}_{n}(T)\right)}^{2}$ and $\mathbb{E}\left[J_{n}(f) J_{m}(g)\right]=$ $\delta_{n m}\langle f, g\rangle_{\mathrm{L}^{2}\left(\mathcal{S}_{n}(T)\right)}$. Then $\|F\|^{2}=\sum_{n \geq 0}\left\|u_{n}\right\|_{\mathrm{L}^{2}\left(\mathcal{S}_{n}(T)\right)}^{2}$.

Definition. Let $F$ be a random variable in $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right)$ whose chaos expansion is given by (2.2). We introduce:

- $P_{n}(F):=J_{n}\left(u_{n}\right)$ the Wiener chaos of order $n$ of $F$.
- $\mathcal{C}_{p}(F):=\sum_{n \leq p} P_{n}(F)$ the chaos decomposition of $F$ up to order $p$, that is,

$$
\begin{align*}
\mathcal{C}_{p}(F)= & \mathbb{E}[F]+\int_{0}^{T} u_{1}\left(s_{1}\right) d B_{s_{1}}+\int_{0}^{T} \int_{0}^{s_{2}} u_{2}\left(s_{2}, s_{1}\right) d B_{s_{1}} d B_{s_{2}} \\
& +\cdots+\int_{0}^{T} \int_{0}^{s_{p}} \cdots \int_{0}^{s_{2}} u_{p}\left(s_{p}, \ldots, s_{1}\right) d B_{s_{1}} \cdots d B_{s_{p}} \tag{2.3}
\end{align*}
$$

We state two lemmas useful for the sequel.
LEMMA 2.2 (Nualart). $\quad F \in \mathbb{D}^{m, 2}$ if and only if $\left\|D^{m} F\right\|_{\mathrm{L}^{2}\left(\Omega \times[0, T]^{m}\right)}^{2}=$ $\sum_{n \geq 0}(n+m-1) \times \cdots \times n \times \mathbb{E}\left[\left|P_{n}(F)\right|^{2}\right]<\infty$. In this case, we have

$$
\sum_{n \geq 0}(n+m-1) \times \cdots \times n \times \mathbb{E}\left[\left|P_{n}(F)\right|^{2}\right] \leq\|F\|_{\mathbb{D}^{m, 2}}^{2} .
$$

From Lemma 2.2, we deduce the following:
Lemma 2.3. Let $F \in \mathbb{D}^{m, 2}$. We have

$$
\mathbb{E}\left[\left|F-\mathcal{C}_{p}(F)\right|^{2}\right] \leq \frac{\left\|D^{m} F\right\|_{\mathrm{L}^{2}\left(\Omega \times[0, T]^{m}\right)}^{2}}{(p+m) \cdots(p+1)}
$$

Proof.

$$
\begin{aligned}
\mathbb{E}\left[\left|F-\mathcal{C}_{p}(F)\right|^{2}\right] & =\sum_{k \geq p+1} \mathbb{E}\left[P_{k}(F)^{2}\right] \\
& =\sum_{k \geq p+1}(k+m-1) \cdots k \times \frac{1}{(k+m-1) \cdots k} \times \mathbb{E}\left[\left|P_{k}(F)\right|^{2}\right] \\
& \leq \frac{1}{(p+m) \cdots(p+1)} \sum_{k \geq p+1}(k+m-1) \cdots k \mathbb{E}\left[\left|P_{k}(F)\right|^{2}\right]
\end{aligned}
$$

The following lemma gives some useful properties of the chaos decomposition.

## Lemma 2.4

- Let $F$ be a r.v. in $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right) . \forall p \geq 1$, we have $\mathbb{E}\left(\left|\mathcal{C}_{p}(F)\right|^{2}\right) \leq \mathbb{E}\left(|F|^{2}\right)$. If $F$ belongs to $\mathrm{L}^{j}\left(\mathcal{F}_{T}\right), \forall j>2, \mathbb{E}\left(\left|\mathcal{C}_{p}(F)\right|^{j}\right) \leq\left(1+p(j-1)^{p / 2}\right)^{j} \mathbb{E}\left(|F|^{j}\right)$.
- Let $H$ be in $\mathrm{H}_{T}^{2}(\mathbb{R})$. We have $\mathcal{C}_{p}\left(\int_{0}^{T} H_{s} d s\right)=\int_{0}^{T} \mathcal{C}_{p}\left(H_{s}\right) d s$.
- For all $F \in \mathbb{D}^{1,2}$ and for all $t \leq r, D_{t} \mathbb{E}_{r}\left[\mathcal{C}_{p}(F)\right]=\mathbb{E}_{r}\left[\mathcal{C}_{p-1}\left(D_{t} F\right)\right]$.

The first result ensues from the fact that for $j>2\left\|P_{n}(F)\right\|_{j} \leq(j-1)^{n / 2}\|F\|_{j}$; see [19], page 63.
2.2.2. Wiener chaos expansion and Hermite polynomials. Another approach to Wiener chaos expansion uses Hermite polynomials. This approach can be easily generalized when considering $d$-dimensional Brownian motions, and so this is the one we consider in the following. We present it for $d=1$. Let $\left\{g_{i}\right\}_{i \geq 1}$ be an orthonormal basis of $\mathrm{L}^{2}(0, T)$. The Wiener chaos of order $n, P_{n}(F)$, is the $\mathrm{L}^{2-}$ closure of the vector field spanned by

$$
\left\{\prod_{i \geq 1} \sqrt{n_{i}!} K_{n_{i}}\left(\int_{0}^{T} g_{i}(s) d B_{s}\right):\left|\left(n_{i}\right)_{i \geq 1}\right|:=\sum n_{i}=n\right\}
$$

where $K_{n}$ is the Hermite polynomial of order $n$ defined by the expansion

$$
e^{x t-t^{2} / 2}=\sum_{n \geq 0} K_{n}(x) t^{n}
$$

with the convention $K_{-1} \equiv 0$. With this normalization, we have $K_{n}^{\prime}(x)=K_{n-1}(x)$ for any integer $n$. It is well known that $\left(K_{n}\right)_{n \geq 0}$ is a sequence of orthogonal polynomials in $\mathrm{L}^{2}(\mathbb{R}, \mu)$, where $\mu$ denotes the reduced centered Gaussian measure. Moreover, we have

$$
\int_{\mathbb{R}} K_{n}^{2}(x) \mu(d x)=\frac{1}{n!}
$$

Every square integrable random variable $F$, measurable with respect to $\mathcal{F}_{T}$, admits the following orthogonal decomposition:

$$
\begin{equation*}
F=d_{0}+\sum_{k \geq 1} \sum_{|n|=k} d_{k}^{n} \prod_{i \geq 1} K_{n_{i}}\left(\int_{0}^{T} g_{i}(s) d B_{s}\right), \tag{2.4}
\end{equation*}
$$

where $n=\left(n_{i}\right)_{i \geq 1}$ is a sequence of positive integers, and where $|n|$ stands for $\sum_{i \geq 1} n_{i}$. Taking into account the normalization of the Hermite polynomials we use, we get

$$
d_{0}=\mathbb{E}[F], \quad d_{k}^{n}=n!\mathbb{E}\left[F \times \prod_{i \geq 1} K_{n_{i}}\left(\int_{0}^{T} g_{i}(s) d B_{s}\right)\right],
$$

where $n!=\prod_{i \geq 1} n_{i}$ !. Before describing the chaos decomposition formulas we use in the algorithm, we give a lemma useful in the sequel.

Lemma 2.5. Let $g \in \mathrm{~L}^{2}(0, T)$, and let $U_{t}=\int_{0}^{t} g^{2}(s) d s$. For $n \in \mathbb{N}$, let us define

$$
M_{t}^{n}=U_{t}^{n / 2} K_{n}\left(B(g)_{t} / \sqrt{U_{t}}\right), \quad B(g)_{t}=\int_{0}^{t} g(s) d B_{s}
$$

Then $\left\{M_{t}^{n}\right\}_{0 \leq t \leq T}$ is a martingale and

$$
d M_{t}^{n}=g(t) M_{t}^{n-1} d B_{t}
$$

2.3. Chaos decomposition formulas. These formulas are based on the decomposition (2.4). To get tractable formulas, we consider a finite number of chaos and a finite number of functions $\left(g_{1}, \ldots, g_{N}\right)$. The $\left(g_{i}\right)_{1 \leq i \leq N}$ functions are chosen such that we can quickly compute $\mathbb{E}\left(F \mid \mathcal{F}_{t}\right)$ and $D_{t} \mathbb{E}\left(F \mid \mathcal{F}_{t}\right)$ [as required in (1.2)]. We develop in this section the case $d=1$, and we refer to Section B. 2 when $d>1$.

The first step consists in considering a finite number of chaos. In order to approximate the random variable $F$, we consider its projection $\mathcal{C}_{p}(F)$ onto the first $p$ chaos, namely

$$
\begin{equation*}
\mathcal{C}_{p}(F)=d_{0}+\sum_{1 \leq k \leq p} \sum_{|n|=k} d_{k}^{n} \prod_{i \geq 1} K_{n_{i}}\left(\int_{0}^{T} g_{i}(s) d B_{s}\right) \tag{2.5}
\end{equation*}
$$

Of course, we still have an infinite number of terms in the previous sum and the second step consists in working with only the first $N$ functions $g_{1}, \ldots, g_{N}$ of an orthonormal basis of $\mathrm{L}^{2}(0, T)$.

Let us consider a regular mesh grid of $N$ time steps $\mathcal{T}=\left\{\bar{t}_{i}=i \frac{T}{N}, i=0, \ldots, N\right\}$ and the $N$ step functions

$$
\begin{equation*}
g_{i}=\mathbf{1}_{\left[\bar{t}_{i-1}, \bar{t}_{i}\right]}(t) / \sqrt{h}, \quad i=1, \ldots, N, \text { where } h:=\frac{T}{N} . \tag{2.6}
\end{equation*}
$$

We complete these $N$ functions $g_{1}, \ldots, g_{N}$ into an orthonormal basis of $\mathrm{L}^{2}(0, T)$, $\left(g_{i}\right)_{i \geq 1}$. For instance, one can consider the Haar basis on each interval $\left(\bar{t}_{i-1}, \bar{t}_{i}\right)$, $i=1, \ldots, N$. We implicitly assume that $N \geq p$. This leads to the following approximation:

$$
\begin{equation*}
\mathcal{C}_{p}^{N}(F)=d_{0}+\sum_{1 \leq k \leq p} \sum_{|n|=k} d_{k}^{n} \prod_{1 \leq i \leq N} K_{n_{i}}\left(\int_{0}^{T} g_{i}(s) d B_{s}\right), \tag{2.7}
\end{equation*}
$$

where $n=\left(n_{1}, \ldots, n_{N}\right)$ and $|n|=n_{1}+\cdots+n_{N}$. Due to the simplicity of the functions $g_{i}, i=1, \ldots, N$, we can compute explicitly

$$
\int_{0}^{T} g_{i}(s) d B_{s}=G_{i} \quad \text { where } G_{i}=\frac{B_{\bar{t}_{i}}-B_{\bar{t}_{i-1}}}{\sqrt{h}}
$$

Roughly speaking this means that $P_{k}$, the $k$ th chaos, is generated by

$$
\left\{K_{n_{1}}\left(G_{1}\right) \cdots K_{n_{N}}\left(G_{N}\right): n_{1}+\cdots+n_{N}=k\right\} .
$$

Thus the approximation we will use for the random variable $F$ is

$$
\begin{align*}
\mathcal{C}_{p}^{N}(F) & =d_{0}+\sum_{k=1}^{p} \sum_{|n|=k} d_{k}^{n} K_{n_{1}}\left(G_{1}\right) \cdots K_{n_{N}}\left(G_{N}\right) \\
& =d_{0}+\sum_{k=1}^{p} \sum_{|n|=k} d_{k}^{n} \prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}\right) \tag{2.8}
\end{align*}
$$

where the coefficients $d_{0}$ and $d_{k}^{n}$ are given by

$$
\begin{equation*}
d_{0}=\mathbb{E}[F], \quad d_{k}^{n}=n!\mathbb{E}\left[F K_{n_{1}}\left(G_{1}\right) \cdots K_{n_{N}}\left(G_{N}\right)\right] \tag{2.9}
\end{equation*}
$$

The following lemma, similar to Lemma 2.4, gives some useful properties of the operator $\mathcal{C}_{p}^{N}$.

Lemma 2.6. Let $F$ be a r.v. in $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right)$ and $H$ be in $\mathrm{H}_{T}^{2}(\mathbb{R})$. Then:

- $\forall(p, N) \in\left(\mathbb{N}^{\star}\right)^{2}, \mathbb{E}\left(\left|\mathcal{C}_{p}^{N}(F)\right|^{2}\right) \leq \mathbb{E}\left(\left|\mathcal{C}_{p}(F)\right|^{2}\right) \leq \mathbb{E}\left(|F|^{2}\right)$.
- $\mathcal{C}_{p}^{N}\left(\int_{0}^{T} H_{s} d s\right)=\int_{0}^{T} \mathcal{C}_{p}^{N}\left(H_{s}\right) d s$.
- For all $t \leq r, D_{t} \mathbb{E}_{r}\left[\mathcal{C}_{p}^{N}(F)\right]=\mathbb{E}_{r}\left[\mathcal{C}_{p-1}^{N}\left(D_{t} F\right)\right]$.

From (2.8), we deduce the expressions of $\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)$ and $D_{t} \mathbb{E}_{t}\left(\mathcal{C}_{p}^{N}(F)\right)$, useful for the approximation of $(Y, Z)$ by the chaos decomposition; see (1.2).

Proposition 2.7. Let $F$ be a real random variable in $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right)$, and let $r$ be an integer in $\{1, \ldots, N\}$. For all $\bar{t}_{r-1}<t \leq \bar{t}_{r}$, we have

$$
\begin{aligned}
& \mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)=d_{0}+ \sum_{k=1}^{p} \sum_{|n(r)|=k} d_{k}^{n} \prod_{i<r} K_{n_{i}}\left(G_{i}\right) \\
& \times\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{n_{r} / 2} K_{n_{r}}\left(\frac{B_{t}-B_{\bar{t}_{r-1}}}{\sqrt{t-\bar{t}_{r-1}}}\right), \\
& D_{t} \mathbb{E}_{t}\left(\mathcal{C}_{p}^{N}(F)\right)=h^{-1 / 2} \sum_{k=1}^{p} \sum_{\substack{|n(r)|=k \\
n_{r}>0}} d_{k}^{n} \prod_{i<r} K_{n_{i}}\left(G_{i}\right) \\
& \times\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{\left(n_{r}-1\right) / 2} K_{n_{r}-1}\left(\frac{B_{t}-B_{\bar{t}_{r-1}}}{\sqrt{t-\bar{t}_{r-1}}}\right),
\end{aligned}
$$

where, if $r \leq N$ and $n=\left(n_{1}, \ldots, n_{N}\right), n(r)$ stands for $\left(n_{1}, \ldots, n_{r}\right)$.

The proof of Proposition 2.7 is postponed to Section B.1.

REMARK 2.8. For $t=\bar{t}_{r}$ and $r \geq 1$, Proposition 2.7 leads to

$$
\begin{aligned}
\mathbb{E}_{\bar{t}_{r}}\left(\mathcal{C}_{p}^{N} F\right) & =d_{0}+\sum_{k=1}^{p} \sum_{|n(r)|=k} d_{k}^{n} \prod_{i \leq r} K_{n_{i}}\left(G_{i}\right), \\
D_{\bar{t}_{r}} \mathbb{E}_{\bar{t}_{r}}\left(\mathcal{C}_{p}^{N} F\right) & =h^{-1 / 2} \sum_{k=1}^{p} \sum_{\substack{|n(r)|=k \\
n_{r}>0}} d_{k}^{n} \prod_{i<r} K_{n_{i}}\left(G_{i}\right) \times K_{n_{r}-1}\left(G_{r}\right) .
\end{aligned}
$$

When $r=0$, we get $\mathbb{E}_{\bar{t}_{0}}\left(\mathcal{C}_{p}^{N} F\right)=d_{0}$, and we define $D_{\bar{t}_{0}} \mathbb{E}_{\bar{t}_{0}}\left(\mathcal{C}_{p}^{N} F\right)=\frac{1}{\sqrt{h}} d_{1}^{e_{1}}[$ which is the limit of $D_{t} \mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)$ when $t$ tends to 0].

Let us end this subsection by some examples.
EXAMPLE 2.9 (Case $p=2$ ). From (2.8)-(2.9), we have

$$
\mathcal{C}_{2}^{N}(F)=d_{0}+\sum_{j=1}^{N} d_{1}^{e_{j}} K_{1}\left(G_{j}\right)+\sum_{j=1}^{N} \sum_{i=1}^{j-1} d_{2}^{e_{i j}} K_{1}\left(G_{i}\right) K_{1}\left(G_{j}\right)+\sum_{j=1}^{N} d_{2}^{2 e_{j}} K_{2}\left(G_{j}\right)
$$

where $e_{j}$ denotes the unit vector whose $j$ th component is one, and $e_{i j}=e_{i}+e_{j}$. For $j=1, \ldots, N$ and $i=1, \ldots, j-1$, it holds

$$
\begin{aligned}
d_{1}^{e_{j}} & =\mathbb{E}\left(F K_{1}\left(G_{j}\right)\right), \quad d_{2}^{e_{i j}}=\mathbb{E}\left(F K_{1}\left(G_{i}\right) K_{1}\left(G_{j}\right)\right), \\
d_{2}^{2 e_{j}} & =2 \mathbb{E}\left(F K_{2}\left(G_{j}\right)\right)
\end{aligned}
$$

Remark 2.8 leads to

$$
\begin{aligned}
\mathbb{E}_{\bar{t}_{r}}\left(\mathcal{C}_{2}^{N} F\right)= & d_{0}+\sum_{j=1}^{r} d_{1}^{e_{j}} K_{1}\left(G_{j}\right)+\sum_{j=1}^{r} \sum_{i=1}^{j-1} d_{2}^{e_{i j}} K_{1}\left(G_{i}\right) K_{1}\left(G_{j}\right) \\
& +\sum_{j=1}^{r} d_{2}^{2 e_{j}} K_{2}\left(G_{j}\right), \\
D_{\bar{t}_{r}} \mathbb{E}_{\bar{t}_{r}}\left(\mathcal{C}_{2}^{N} F\right)= & h^{-1 / 2}\left(d_{1}^{e_{r}}+d_{2}^{2 e_{r}} K_{1}\left(G_{r}\right)+\sum_{i=1}^{r-1} d_{2}^{e_{i r}} K_{1}\left(G_{i}\right)\right) .
\end{aligned}
$$

3. Description of the algorithm. The algorithm is based on four types of approximations: Picard's iterations, a Wiener chaos expansion up to a finite order, the truncation of an $\mathrm{L}^{2}(0, T)$ basis in order to apply formulas of Proposition 2.7, and a Monte Carlo method to approximate the coefficients $d_{0}$ and $d_{k}^{n}$ defined in (2.9). We present the first three steps of the approximation procedure in Section 3.1. The Monte Carlo method and the practical implementation are presented in Section 3.2.

### 3.1. Approximation procedure.

3.1.1. Picard's iterations. The first step consists in approximating $(Y, Z)$ the solution to (1.1)—by Picard's sequence $\left(Y^{q}, Z^{q}\right)_{q}$, built as follows: $\left(Y^{0}=\right.$ $0, Z^{0}=0$ ) and for all $q \geq 1$

$$
\begin{equation*}
Y_{t}^{q+1}=\xi+\int_{t}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s-\int_{t}^{T} Z_{s}^{q+1} \cdot d B_{s}, \quad 0 \leq t \leq T \tag{3.1}
\end{equation*}
$$

From (3.1), under the assumptions that $\xi \in \mathbb{D}^{1,2}$ and $f \in C_{b}^{0,1,1}$, we express $\left(Y^{q+1}, Z^{q+1}\right)$ as a function of the processes $\left(Y^{q}, Z^{q}\right)$,

$$
\begin{equation*}
Y_{t}^{q+1}=\mathbb{E}_{t}\left(\xi+\int_{t}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s\right), \quad Z_{t}^{q+1}=D_{t} Y_{t}^{q+1} \tag{3.2}
\end{equation*}
$$

which can also be written

$$
\begin{align*}
Y_{t}^{q+1} & =\mathbb{E}_{t}\left(\xi+\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s\right)-\int_{0}^{t} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s \\
Z_{t}^{q+1} & =D_{t} Y_{t}^{q+1} \tag{3.3}
\end{align*}
$$

As we recalled in the Introduction, the computation of the conditional expectation is the cornerstone in the numerical resolution of BSDEs. Chaos decomposition formulas enable us to circumvent this problem.
3.1.2. Wiener Chaos expansion. Computing the chaos decomposition of the r.v. $F=\xi+\int_{t}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s$ [appearing in (3.2)] in order to compute $Y_{t}^{q+1}$ is not judicious. $F$ depends on $t$, and then the computation of $Y^{q+1}$ on the grid $\mathcal{T}=\left\{\bar{t}_{i}=i \frac{T}{N}, i=0, \ldots, N\right\}$ would require $N+1$ calls to the chaos decomposition function. To build an efficient algorithm, we need to call the chaos decomposition function as infrequently as possible, since each call is computationally demanding and brings an approximation error due to the truncation and to the Monte Carlo approximation (see next sections). Then we look for a r.v. $F^{q}$ independent of $t$ such that $Y_{t}^{q+1}$ and $Z_{t}^{q+1}$ can be expressed as functions of $\mathbb{E}_{t}\left(F^{q}\right), D_{t} \mathbb{E}_{t}\left(F^{q}\right)$ and of $Y^{q}$ and $Z^{q}$. Equation (3.3) gives a more tractable expression of $Y^{q+1}$. Let $F^{q}$ be defined by $F^{q}:=\xi+\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s$. Then

$$
\begin{equation*}
Y_{t}^{q+1}=\mathbb{E}_{t}\left(F^{q}\right)-\int_{0}^{t} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s, \quad Z_{t}^{q+1}=D_{t} \mathbb{E}_{t}\left(F^{q}\right) \tag{3.4}
\end{equation*}
$$

The second type of approximation consists of computing the chaos decomposition of $F^{q}$ up to order $p$. Since $F^{q}$ does not depend on $t$, the chaos decomposition function $\mathcal{C}_{p}$ is called only once per Picard's iteration.

Let $\left(Y^{q, p}, Z^{q, p}\right)$ denote the approximation of $\left(Y^{q}, Z^{q}\right)$ built at step $q$ using a chaos decomposition with order $p:\left(Y^{0, p}, Z^{0, p}\right)=(0,0)$ and

$$
\begin{align*}
Y_{t}^{q+1, p} & =\mathbb{E}_{t}\left[\mathcal{C}_{p}\left(F^{q, p}\right)\right]-\int_{0}^{t} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right) d s \\
Z_{t}^{q+1, p} & =D_{t} \mathbb{E}_{t}\left[\mathcal{C}_{p}\left(F^{q, p}\right)\right] \tag{3.5}
\end{align*}
$$

where $F^{q, p}=\xi+\int_{0}^{T} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right) d s$. In the sequel, we also use the following equality:

$$
\begin{equation*}
Z_{t}^{q+1, p}=\mathbb{E}_{t}\left[D_{t} \mathcal{C}_{p}\left(F^{q, p}\right)\right] \tag{3.6}
\end{equation*}
$$

3.1.3. Truncation of the basis. The third type of approximation comes from the truncation of the orthonormal $\mathrm{L}^{2}(0, T)$ basis used in the definition of $\mathcal{C}_{p}(2.5)$. Instead of considering a basis of $\mathrm{L}^{2}(0, T)$, we only keep the first $N$ functions $\left(g_{1}, \ldots, g_{N}\right)$ defined by (2.6) to build the chaos decomposition function $\mathcal{C}_{p}^{N}$ (2.7). Proposition 2.7 gives us explicit formulas for $\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)$ and $D_{t} \mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)$. From (3.5), we build $\left(\left(Y^{q, p, N}, Z^{q, p, N}\right)_{q}\right.$ in the following way: $\left(\left(Y^{0, p, N}, Z^{0, p, N}\right)=(0,0)\right.$ and

$$
\begin{align*}
Y_{t}^{q+1, p, N} & =\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N}\left(F^{q, p, N}\right)\right)-\int_{0}^{t} f\left(s, Y_{s}^{q, p, N}, Z_{s}^{q, p, N}\right) d s  \tag{3.7}\\
Z_{t}^{q+1, p, N} & =D_{t}\left(\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N}\left(F^{q, p, N}\right)\right)\right)
\end{align*}
$$

where $F^{q, p, N}:=\xi+\int_{0}^{T} f\left(s, Y_{s}^{q, p, N}, Z_{s}^{q, p, N}\right) d s$.
Equation (3.7) is tractable as soon as we know closed formulas for the coefficients $d_{k}^{n}$ of the chaos decomposition of $\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N}\left(F^{q, p, N}\right)\right)$ and $D_{t}\left(\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N}\left(F^{q, p, N}\right)\right)\right)$; see Proposition 2.7. When it is not the case, we need to use a Monte Carlo method to approximate these coefficients. The next section is devoted to this method and to the practical implementation. In particular, we give the pseudo-code of the algorithm.
3.2. Implementation. In this section, we first explain how to practically compute the chaos decomposition $\mathcal{C}_{p}^{N}(F)$ of a r.v. $F$. Then we give the pseudo-code of the algorithm.
3.2.1. Monte Carlo simulations of the chaos decomposition. Let $F$ denote a r.v. of $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right)$. Practically, when we are not able to compute exactly $d_{0}$ and/or the coefficients $d_{k}^{n}$ of the chaos decomposition (2.8)-(2.9) of $F$, we use Monte Carlo simulations to approximate them. Let $\left(F^{m}\right)_{1 \leq m \leq M}$ be a $M$ i.i.d. sample of $F$ and $\left(G_{1}^{m}, \ldots, G_{N}^{m}\right)_{1 \leq m \leq M}$ be a $M$ i.i.d. sample of $\left(G_{1}, \ldots, G_{N}\right)$. We recall
that $d_{0}$ and the coefficients $\left(d_{k}^{n}\right)_{1 \leq k \leq p,|n|=k}$ are given by $d_{0}=\mathbb{E}[F]$ and $d_{k}^{n}=$ $n!\mathbb{E}\left[F K_{n_{1}}\left(G_{1}\right) \cdots K_{n_{N}}\left(G_{N}\right)\right]$; see (2.9). Then they are solutions of

$$
\begin{equation*}
\underset{\mathbf{c}=\left(c_{0},\left(c_{k}^{n}\right)_{1 \leq k \leq p,|n|=k}^{\arg \min }\right.}{ } \mathbb{E}\left[|F-\psi(c, G)|^{2}\right], \tag{3.8}
\end{equation*}
$$

where $\psi:(\mathbf{c}, G) \longmapsto c_{0}+\sum_{k=1}^{p} \sum_{|n|=k} c_{k}^{n} \prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}\right)$. We propose two methods to approximate $\mathbf{d}:=\left(d_{0},\left(d_{k}^{n}\right)_{1 \leq k \leq p,|n|=k}\right)$ :

- the first one consists in approximating the expectations of (2.9) by empirical means $\widehat{\mathbf{d}_{\mathbf{M}}}:=\left(\hat{d}_{0}, \hat{d}_{k}^{n} \quad 1 \leq k \leq p,|n|=k\right)$ where

$$
\begin{equation*}
\widehat{d_{0}}:=\frac{1}{M} \sum_{m=1}^{M} F^{m}, \quad \widehat{d_{k}^{n}}:=\frac{n!}{M} \sum_{m=1}^{M} F^{m} K_{n_{1}}\left(G_{1}^{m}\right) \cdots K_{n_{N}}\left(G_{N}^{m}\right) \tag{3.9}
\end{equation*}
$$

- the second one is based on a sample average approximation

$$
\overline{\mathbf{d}_{\mathbf{M}}}:=\left(\overline{d_{0}}, \overline{d_{k}^{n}} 1 \leq k \leq p,|n|=k\right)=\underset{c_{0},\left(c_{k}^{n}\right)_{1 \leq k \leq p,|n|=k}^{\arg \min }}{ } \frac{1}{M} \sum_{m=1}^{M}\left|F^{m}-\psi\left(\mathbf{c}, G^{m}\right)\right|^{2}
$$

REMARK 3.1. In terms of computation time, the first method is much faster than the second one.

- The first method requires $O(M \times p)$ computations per coefficient. Since we are looking for $O\left(N^{p}\right)$ coefficients, its computational cost is $O\left(M \times p \times N^{p}\right)$.
- The second method requires $O\left(M \times p \times N^{p}\right)$ computations to evaluate $\frac{1}{M} \sum_{m=1}^{M}\left|F^{m}-\psi\left(c, G^{m}\right)\right|^{2}$ (in fact, it requires the same number of computations as the first method, since the function $\psi$ contains as many additions as coefficients, and each addition contains as many products as the associated coefficient). We still have to compute the argmin, the computational cost of which depends on the method we use.

From a theoretical point of view, the second method gives better convergence results than the first one. For the first method, we only know that $\widehat{\mathbf{d}_{\mathbf{M}}}$ converges to $\mathbf{d}$ a.s. Concerning the second method, we know that $\overline{\mathbf{d}_{\mathbf{M}}}$ converges to $\mathbf{d}$ a.s., and under regularity assumptions on $\psi$, the uniform strong law of large numbers gives the a.s. convergence of $\frac{1}{M} \sum_{m=1}^{M}\left|F^{m}-\psi\left(\overline{\mathbf{d}_{\mathbf{M}}}, G^{m}\right)\right|^{2}$ to $\mathbb{E}\left[|F-\psi(\mathbf{d}, G)|^{2}\right]$.

In the following, $\mathcal{C}_{p}^{N, M}(F)$ denotes the approximation of the chaos decomposition of order $p$ of $F$ when using the first method to approximate the coefficients $d_{k}^{n}$ :

$$
\begin{equation*}
\mathcal{C}_{p}^{N, M}(F)=\widehat{d_{0}}+\sum_{k=1}^{p} \sum_{|n|=k} \widehat{d_{k}^{n}} \prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}\right) \tag{3.10}
\end{equation*}
$$

$\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M}(F)\right)$ and $D_{t}\left(\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M}(F)\right)\right)$ denote the conditional expectations obtained in Proposition 2.7 when $\left(d_{0}, d_{k}^{n}\right)_{1 \leq k \leq p,|n|=k}$ are replaced by $\left(\widehat{d_{0}}, \widehat{d_{k}^{n}}\right)_{1 \leq k \leq p,|n|=k}$,

$$
\begin{aligned}
& \mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M} F\right):= \widehat{d_{0}}+ \\
& \sum_{k=1}^{p} \sum_{|n(r)|=k} \widehat{d}_{k}^{n} \prod_{i<r} K_{n_{i}}\left(G_{i}\right) \\
& \times\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{n_{r} / 2} K_{n_{r}}\left(\frac{B_{t}-B_{\bar{t}_{r-1}}}{\sqrt{t-\bar{t}_{r-1}}}\right), \\
& D_{t} \mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M}(F)\right):=h^{-1 / 2} \sum_{k=1}^{p} \sum_{\substack{n(r) \mid=k \\
n_{r}>0}} \widehat{d_{k}^{n}} \prod_{i<r} K_{n_{i}}\left(G_{i}\right) \\
& \times\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{\left(n_{r}-1\right) / 2} K_{n_{r}-1}\left(\frac{B_{t}-B_{\bar{t}_{r-1}}}{\sqrt{t-\bar{t}_{r-1}}}\right) .
\end{aligned}
$$

REMARK 3.2. When $M$ samples of $\mathcal{C}_{p}^{N, M}(F)$ are needed, we can either use the same samples as the ones used to compute $\widehat{d_{0}}$ and $\widehat{d_{k}^{n}}:\left(\widehat{\mathcal{C}_{p}^{N}}(F)\right)^{m}=$ $\widehat{d_{0}}+\sum_{k=1}^{p} \sum_{|n|=k} \widehat{d_{k}^{n}} \prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}^{m}\right)$, or use new ones. In the first case, we only require $M$ samples of $F$ and $\left(G_{1}, \ldots, G_{N}\right)$. The coefficients $\widehat{d_{k}^{n}}$ and $\widehat{d_{0}}$ are not independent of $\prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}^{m}\right)$. The notation $\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M}(F)\right)$ introduced above cannot be linked to $\mathbb{E}\left(\mathcal{C}_{p}^{N, M} F \mid \mathcal{F}_{t}\right)$. In the second case, the coefficients $\widehat{d_{k}^{n}}$ and $\widehat{d_{0}}$ are independent of $\prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}^{m}\right)$, and we have $\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M} F\right)=\mathbb{E}\left(\mathcal{C}_{p}^{N, M} F \mid \mathcal{F}_{t}\right)$. This second approach requires $2 M$ samples of $F$ and $\left(G_{1}, \ldots, G_{N}\right)$, and its variance increases with $N$. Practically, we use the first technique.

We introduce the processes $\left(Y^{q+1, p, N, M}, Z^{q+1, p, N, M}\right)$, which is useful in the following. It corresponds to the approximation of $\left(Y^{q+1, p, N}, Z^{q+1, p, N}\right)$ when we use $\mathcal{C}_{p}^{N, M}$ instead of $\mathcal{C}_{p}^{N}$, that is, when we use a Monte Carlo procedure to compute the coefficients $d_{k}^{n}$.

$$
\begin{align*}
Y_{t}^{q+1, p, N, M} & =\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M}\left(F^{q, p, N, M}\right)\right)-\int_{0}^{t} f\left(\theta_{s}^{q, p, N, M}\right) d s, Z_{t}^{q+1, p, N, M} \\
& =D_{t}\left(\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N, M}\left(F^{q, p, N, M}\right)\right)\right) \tag{3.11}
\end{align*}
$$

where $F^{q, p, N, M}:=\xi+\int_{0}^{T} f\left(\theta_{s}^{q, p, N, M}\right) d s$ and $\theta_{s}^{q, p, N, M}=\left(s, Y_{s}^{q, p, N, M}\right.$, $\left.Z_{S}^{q, p, N, M}\right)$.
3.2.2. Pseudo-code of the algorithm. In this section, we describe in details the algorithm. We aim at computing $M$ trajectories of an approximation of $(Y, Z)$ on the grid $\mathcal{T}=\left\{\bar{t}_{i}=i \frac{T}{N}, i=0, \ldots, N\right\}$. Starting from $\left(Y^{0, p, N, M}, Z^{0, p, N, M}\right)=$
$(0,0),(3.11)$ enables to get $\left(Y^{q, p, N, M}, Z^{q, p, N, M}\right)$ for each of Picard's iterations $q$ on $\mathcal{T}$. Practically, we discretize the integral $\int_{0}^{t} f\left(\theta_{s}^{q, p, N, M}\right) d s$ which leads to approximated values of $\left(Y^{q, p, N, M}, Z^{q, p, N, M}\right)$ computed on a grid.

Let us introduce $\left(\bar{Y}_{\bar{t}_{i}}^{q+1, p, N, M}, \bar{Z}_{\bar{t}_{i}}^{q+1, p, N, M}\right)_{1 \leq i \leq N}$, defined by $\left(\bar{Y}^{0, p, N, M}\right.$, $\left.\bar{Z}^{0, p, N, M}\right)=(0,0)$ and for all $q \geq 0$

$$
\begin{align*}
& \bar{Y}_{\bar{t}_{i}}^{q+1, p, N, M}=\mathbb{E}_{\bar{t}_{i}}\left(\mathcal{C}_{p}^{N, M}\left(\bar{F}^{q, p, N, M}\right)\right)-h \sum_{j=1}^{i} f\left(\bar{t}_{j}, \bar{Y}_{\bar{t}_{j}}^{q, p, N, M}, \bar{Z}_{\bar{t}_{j}}^{q, p, N, M}\right), \\
& \bar{Z}_{\bar{t}_{i}}^{q+1, p, N, M}=D_{\bar{t}_{i}}\left(\mathbb{E}_{\bar{t}_{i}}\left(\mathcal{C}_{p}^{N, M}\left(\bar{F}^{q, p, N, M}\right)\right)\right), \tag{3.12}
\end{align*}
$$

where $\bar{F}^{q, p, N, M}:=\xi+h \sum_{i=1}^{N} f\left(\bar{t}_{i}, \bar{Y}_{\bar{t}_{i}}^{q, p, N, M}, \bar{Z}_{\bar{t}_{i}}^{q, p, N, M}\right)$. Here is the notation we use in the algorithm:

- $d$ : dimension of the Brownian motion;
- $q$ : index of Picard's iteration;
- $K_{i t}$ : number of Picard's iterations;
- $M$ : number of Monte Carlo samples;
- $N$ : number of time steps used for the discretization of $Y$ and $Z$;
- $p$ : order of the chaos decomposition;
- $\mathbf{Y}^{q} \in \mathcal{M}_{N+1, M}(\mathbb{R})$ represents $M$ paths of $\bar{Y}^{q, p, N, M}$ computed on the grid $\mathcal{T}$;
- for all $l \in\{1, \ldots, d\},\left(\mathbf{Z}^{q}\right)_{l} \in \mathcal{M}_{N+1, M}(\mathbb{R})$ represents $M$ paths of $\left(\bar{Z}^{q, p, N, M}\right)_{l}$ computed on the $\operatorname{grid} \mathcal{T}$.

Since $\xi \in \mathrm{L}^{2}\left(\mathcal{F}_{T}\right), \xi$ can be written as a measurable function of the Brownian path. Then one gets one sample of $\xi$ from one sample of $\left(G_{1}, \ldots, G_{N}\right)$ (where $G_{i}$ represents $\frac{B_{\bar{t}_{i}}-B_{\bar{t}_{i-1}}}{\sqrt{h}}$.

For the sake of clarity, we detail the algorithm for $d=1$.
Let us now deal with the complexity of the algorithm:
For each $q$ :

- the computation of the vector $F^{q}$ (loop line 5) requires $O(M \times N)$ computations;
- the computation of the vector $\mathbf{d}$ (line 8 ) requires $O\left(M \times p \times(N \times d)^{p}\right)$ computations [in dimension $d$ we have $O\left((N \times d)^{p}\right)$ coefficients, and the computation of each coefficient requires $O(M \times p)$ computations (see Remark 3.1)];
- for each $N$ and $M$ (lines 10-11):
- the computation of $\left(\mathbb{E}_{\bar{t}_{j}}\left(\mathcal{C}_{p}^{N, M} F^{q}\right)\right)^{m}$ and of $\left(D_{\bar{t}_{j}}^{l}\left(\mathbb{E}_{\bar{t}_{j}}\left(\mathcal{C}_{p}^{N, M} F^{q}\right)\right)\right)_{1 \leq l \leq d}^{m}$ (line 12) requires $O\left(d \times p \times(N \times d)^{p}\right)$ computations
- the computation of $\left(\mathbf{Y}^{q+1}\right)_{j, m}$ (loop line 13) requires $O(N)$ computations and the computation of $\left(\left(\mathbf{Z}^{q+1}\right)_{j, m}^{l}\right)_{1 \leq l \leq d}$ requires $O(d)$ computations.
The complexity of the algorithm is then $O\left(K_{i t} \times M \times p \times(N \times d)^{p+1}\right)$.

```
Algorithm 1 Iterative algorithm
    Pick at random \(N \times M\) values of standard Gaussian r.v. stored in \(\mathbf{G}\).
    Using G, compute \(\left(\xi^{m}\right)_{0 \leq m \leq M-1}\).

```

4. Convergence results. We aim at bounding the error between $(Y, Z)$-the solution of (1.1)—and ( $Y^{q, p, N, M}, Z^{q, p, N, M}$ ) defined by (3.11). Before stating the main result of the paper, we introduce some hypotheses.

In the following, $\left(t_{1}, \ldots, t_{n}\right)$ and $\left(s_{1}, \ldots, s_{n}\right)$ denote two vectors such that

$$
0 \leq t_{1} \leq \cdots \leq t_{n} \leq T, 0 \leq s_{1} \leq \cdots \leq s_{n} \leq T \text { and } \forall i, s_{i} \leq t_{i} .
$$

Hypothesis 4.1 (Hypothesis $\mathcal{H}_{m}$ ). Let $m \in \mathbb{N}^{*}$. We say that $F$ satisfies Hypothesis $\mathcal{H}_{m}$ if $F$ satisfies the two following hypotheses:

- $\mathcal{H}_{m}^{1}: \forall j \geq 2 F \in \mathcal{D}^{m, j}$, that is, $\|F\|_{m, j}^{j}<\infty$;
- $\mathcal{H}_{m}^{2}: \forall j \geq 2, \forall i \in\{1, \ldots, m\}, \forall l_{0} \leq i-1, \forall l_{1} \leq m-i, \forall l \in\{1, \ldots, d\}$ and for all multi-indices $\alpha_{0}$ and $\alpha_{1}$ such that $\left|\alpha_{0}\right|=l_{0}$ and $\left|\alpha_{1}\right|=l_{1}+1$, there exist two positive constants $\beta_{F}$ and $k_{l}^{F}$ such that

$$
\begin{aligned}
& \sup _{t_{1} \leq \cdots \leq t_{0}} \sup _{s_{i+1} \leq \cdots \leq s_{i+l_{1}}} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{0}}^{\alpha_{0}}\left(D_{t_{i}, s_{i+1}, \ldots, s_{i+l_{1}}^{\alpha_{1}}} F-D_{s_{i}, \ldots, s_{i+l_{1}}^{\alpha_{1}}}^{\alpha_{1}} F\right)\right|^{j}\right] \\
& \quad \leq k_{l}^{F}(j)\left(t_{i}-s_{i}\right)^{j \beta_{F}}
\end{aligned}
$$

where $l=l_{0}+l_{1}+1$. In the following, we denote $K_{m}^{F}(j)=\sup _{l \leq m} k_{l}^{F}(j)$.

REMARK 4.2. If $F$ satisfies $\mathcal{H}_{m}^{2}$, for all multi-index $\alpha$ such that $|\alpha|=l$, we have

$$
\begin{equation*}
\left|\mathbb{E}\left(D_{t_{1}, \ldots, t_{l}}^{\alpha} F\right)-\mathbb{E}\left(D_{s_{1}, \ldots, s_{l}}^{\alpha} F\right)\right| \leq K_{l}^{F}\left(\left(t_{1}-s_{1}\right)^{\beta_{F}}+\cdots+\left(t_{l}-s_{l}\right)^{\beta_{F}}\right) \tag{4.1}
\end{equation*}
$$

where $K_{l}^{F}$ is a constant.
Hypothesis 4.3 (Hypothesis $\mathcal{H}_{p, N}^{3}$ ). $\quad$ Let $(p, N) \in \mathbb{N}^{2}$. We say that an r.v. $F$ satisfies $\mathcal{H}_{p, N}^{3}$ if

$$
V_{p, N}(F):=\mathbb{V}(F)+\sum_{k=1}^{p} \sum_{|n|=k} n!\mathbb{V}\left(F \prod_{i=1}^{N} K_{n_{i}}\left(G_{i}\right)\right)<\infty
$$

REMARK 4.4. If $F$ is bounded by $K$, we get $V_{p, N}(F) \leq K^{2} \sum_{k=0}^{p}\binom{N}{k}$. Then every bounded r.v. satisfies $\mathcal{H}_{p, N}^{3}$.

This remark ensues from $\mathbb{E}\left(\prod_{i=1}^{N} K_{n_{i}}^{2}\left(G_{i}\right)\right)=\frac{1}{n!}$.
REMARK 4.5. Let $X$ be the $\mathbb{R}^{n}$-valued process solution of

$$
X_{t}=x+\int_{0}^{t} b\left(s, X_{s}\right) d s+\int_{0}^{t} \sigma\left(s, X_{s}\right) d B_{s}
$$

where $B$ is a $d$-dimensional Brownian motion and $b:[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ and $\sigma:[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n \times d}$ are two $C^{0, m}$ functions uniformly Lipschitz w.r.t. $x$ and Hölder continuous of parameter $\frac{1}{2}$ w.r.t. $t$, with linear growth in $x$ and with bounded derivatives. Then, every random variable $\xi$ of type $g\left(X_{T}\right)$ or $g\left(\int_{0}^{T} X_{S} d s\right)$ with $g: \mathbb{R}^{n} \rightarrow \mathbb{R}$ in $C_{p}^{\infty}$ satisfies $\mathcal{H}_{m}$ and $\mathcal{H}_{p, N}^{3}$, for all $p$ and $N$.

We refer to Section A. 1 for the proof of Remark 4.5.
THEOREM 4.6. Let $k$ be an integer s.t. $k \leq p$. Assume that $\xi$ satisfies $\mathcal{H}_{p+q}$ and $\mathcal{H}_{p, N}^{3}$ and $f \in C_{b}^{0, p+q-1, p+q-1}$. We have

$$
\begin{aligned}
\|(Y & \left.-Y^{q, p, N, M}, Z-Z^{q, p, N, M}\right) \|_{\mathrm{L}^{2}}^{2} \\
& \leq \frac{A_{0}}{2^{q}}+\frac{A_{1}(q, k)}{(p+1)^{k}}+A_{2}(q, p)\left(\frac{T}{N}\right)^{2 \beta_{\xi} \wedge 1}+\frac{A_{3}(q, p, N)}{M}
\end{aligned}
$$

where $A_{0}$ is given in Section 4.1, $A_{1}$ is given in Proposition 4.11, $A_{2}$ is given in Proposition 4.15, and $A_{3}$ is given in Proposition 4.17.

If $f \in C_{b}^{0, \infty, \infty}$ and $\xi$ satisfies $\mathcal{H}_{\infty}$ and $\mathcal{H}_{\infty, \infty}^{3}$, we get

$$
\lim _{q \rightarrow \infty} \lim _{p \rightarrow \infty} \lim _{N \rightarrow \infty} \lim _{M \rightarrow \infty}\left\|\left(Y-Y^{q, p, N, M}, Z-Z^{q, p, N, M}\right)\right\|_{\mathrm{L}^{2}}^{2}=0
$$

REMARK 4.7. If $f$ is a path-dependent generator, Theorem 4.6 still holds true under the following hypotheses: $\forall l \leq p, \forall j \geq 2$, for all multi-index $\alpha$ in $\{1, \ldots, d+1\}^{l}(d$ is the dimension of the Brownian motion) s.t. $a(i)=d+1$ means that the Malliavin derivative w.r.t. $t_{i}$ concerns the path-dependent component, and we assume

$$
\begin{aligned}
& \int_{0}^{T}\left\|D_{t_{1}, \ldots, t_{l}}^{\alpha} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right\|_{L^{2}\left(\Omega \times[0, T]^{m}\right)}^{2} d s<\infty \\
& \int_{0}^{T} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{\alpha} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right|^{j}\right] d s<\infty \\
& \int_{0}^{T} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{\alpha} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right)\right|^{j}\right] d s<\infty \quad \text { and } \\
& \left|\mathbb{E}\left(D_{t_{1}, \ldots, t_{l}}^{\alpha} I_{q, p}\right)-\mathbb{E}\left(D_{s_{1}, \ldots, s_{l}}^{\alpha} I_{q, p}\right)\right| \\
& \quad \leq K_{l}^{I_{q, p}}\left(\left(t_{1}-s_{1}\right)^{\beta_{I_{q, p}}}+\cdots+\left(t_{l}-s_{l}\right)^{\beta_{q, p}}\right),
\end{aligned}
$$

where $I_{q, p}=\int_{0}^{T} f\left(\theta_{r}^{q, p}\right) d r$, and $K_{l}^{I_{q, p}}$ and $\beta_{I_{q, p}}$ are two positive constants.
REMARK 4.8. Given the complexity $C_{0}$ of the algorithm (and a given value of $d$ ), we can choose the parameters $p, q, N$ and $M$ such that they minimize the error $\frac{A_{0}}{2^{q}}+\frac{A_{1}(q, p)}{(p+1)^{p}}+A_{2}(q, p)\left(\frac{T}{N}\right)^{a}+\frac{A_{3}(q, p, N)}{M}$, where $a:=2 \beta_{\xi} \wedge 1$. This boilds down to solving the following constrained minimization problem:

$$
\min _{q, p, N, M \text { s.t. } q p M N^{p+1}=C_{0}}\left(\frac{1}{2^{q}}+\frac{C^{q}}{(p+1)^{p}}+\frac{C^{q}}{N^{a}}+\frac{C^{q} N^{p}}{M}\right) .
$$

The Karush-Kuhn-Tucker theorem gives $M \sim \frac{2 p}{a}(p+1)^{p+p^{2} / a}, N \sim(p+$ 1) ${ }^{p / a}, q \sim \frac{1}{\ln (2 C)} p \ln (p+1)$ and $p$ such that $(p+1)^{2 p(1+p / a)} p^{3} \ln (p+1) \sim$ $a \log (2 C) C_{0}$.

Proof of Theorem 4.6. We split the error into 4 terms:
(1) Picard's iterations. $\mathcal{E}^{q}=\left\|\left(Y-Y^{q}, Z-Z^{q}\right)\right\|_{\mathrm{L}^{2}}^{2}$, where $\left(Y^{q}, Z^{q}\right)$ is defined by (3.1);
(2) the truncation of the chaos decomposition. $\mathcal{E}^{q, p}=\|\left(Y^{q}-Y^{q, p}, Z^{q}-\right.$ $\left.Z^{q, p}\right) \|_{\mathrm{L}^{2}}^{2}$, where $\left(Y^{q, p}, Z^{q, p}\right)$ is defined by (3.5);
(3) the truncation of the $\mathrm{L}^{2}(0, T)$ basis. $\mathcal{E}^{q, p, N}=\|\left(Y^{q, p}-Y^{q, p, N}, Z^{q, p}-\right.$ $\left.Z^{q, p, N}\right) \|_{\mathrm{L}^{2}}^{2}$, where $\left(Y^{q, p, N}, Z^{q, p, N}\right)$ is defined by (3.7);
(4) the Monte Carlo approximation to compute the expectations. $\mathcal{E}^{q, p, N, M}=$ $\left\|\left(Y^{q, p, N}-Y^{q, p, N, M}, Z^{q, p, N}-Z^{q, p, N, M}\right)\right\|_{\mathrm{L}^{2}}^{2}$, where $\left(Y^{q, p, N, M}, Z^{q, p, N, M}\right)$ is defined by (3.11).

We have

$$
\left\|\left(Y-Y^{q, p, N, M}, Z-Z^{q, p, N, M}\right)\right\|_{\mathrm{L}^{2}}^{2} \leq 4\left(\mathcal{E}^{q}+\mathcal{E}^{q, p}+\mathcal{E}^{q, p, N}+\mathcal{E}^{q, p, N, M}\right)
$$

It remains to combine (4.2), Propositions 4.11, 4.15 and 4.17 to get the first result.
4.1. Picard's iterations. The first type of error has already been studied in [20] and [12], and we only recall the main result.

HYPOTHESIS 4.9. We assume:

- the generator $f: \mathbb{R}^{+} \times \mathbb{R} \times \mathbb{R}^{d} \longrightarrow \mathbb{R}$ is Lipschitz continuous: there exists a constant $L_{f}$ such that for all $t \in \mathbb{R}^{+}, y_{1}, y_{2} \in \mathbb{R}$ and $z_{1}, z_{2} \in \mathbb{R}^{d}$

$$
\left|f\left(t, y_{1}, z_{1}\right)-f\left(t, y_{2}, z_{2}\right)\right| \leq L_{f}\left(\left|y_{1}-y_{2}\right|+\left|z_{1}-z_{2}\right|\right)
$$

- $\mathbb{E}\left[|\xi|^{2}+\int_{0}^{T}|f(s, 0,0)|^{2} d s\right]<\infty$.

From [12], Corollary 2.1, we know that under Hypothesis 4.9, the sequence $\left(Y^{q}, Z^{q}\right)_{q}$ defined by (3.1) converges to $(Y, Z) d \mathbb{P} \times d t$ a.s. and in $\mathrm{S}_{T}^{2}(\mathbb{R}) \times$ $\mathrm{H}_{T}^{2}\left(\mathbb{R}^{d}\right)$. Moreover, we have

$$
\begin{equation*}
\mathcal{E}^{q}:=\left\|\left(Y-Y^{q}, Z-Z^{q}\right)\right\|_{\mathrm{L}^{2}}^{2} \leq \frac{A_{0}}{2^{q}} \tag{4.2}
\end{equation*}
$$

where $A_{0}$ depends on $T,\|\xi\|^{2}$ and on $\|f(\cdot, 0,0)\|_{\mathrm{L}_{(0, T)}^{2}}^{2}$.
4.2. Error due to the truncation of the chaos decomposition. We assume that the integrals are computed exactly, as well as expectations. The error is only due to the truncation of the chaos decomposition $\mathcal{C}_{p}$ introduced in (2.3).

For the sequel, we also need the following lemma. We postpone its proof to the Appendix A.2.

Lemma 4.10. Assume that $\xi$ satisfies $\mathcal{H}_{m+q}^{1}$ and $f \in \mathcal{C}_{b}^{0, m+q-1, m+q-1}$. Then $\forall q^{\prime} \leq q, \forall p \in \mathbb{N},\left(Y^{q^{\prime}}, Z^{q^{\prime}}\right)$ and $\left(Y^{q^{\prime}, p}, Z^{q^{\prime}, p}\right)$ belong to $\mathcal{S}^{m, \infty}$. Moreover

$$
\begin{aligned}
& \left\|\left(Y^{q}, Z^{q}\right)\right\|_{m, j}^{j}+\left\|\left(Y^{q, p}, Z^{q, p}\right)\right\|_{m, j}^{j} \\
& \quad \leq C\left(\|\xi\|_{m+q,((m+q-1)!/ m!) j},\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{k \leq m+q-1}\right)
\end{aligned}
$$

where $C$ is a constant depending on $\|\xi\|_{m+q,((m+q-1)!/ m!) j}$ and on $\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{k \leq m+q-1}$.

Proposition 4.11. Let $m \in \mathbb{N}^{\star}$. Assume that $\xi$ satisfies $\mathcal{H}_{m+q}^{1}$ and $f \in$ $C_{b}^{0, m+q-1, m+q-1}$. We recall $\mathcal{E}^{q, p}=\left\|\left(Y^{q}-Y^{q, p}, Z^{q}-Z^{q, p}\right)\right\|_{\mathrm{L}^{2}}^{2}$. We get

$$
\begin{equation*}
\mathcal{E}^{q+1, p} \leq C_{1} T(T+1) L_{f}^{2} \mathcal{E}^{q, p}+\frac{K_{1}(q, m)}{(p+1) \cdots(p+m)}, \tag{4.3}
\end{equation*}
$$

where $C_{1}$ is a scalar and $K_{1}(q, m)$ depends on $T, m,\|\xi\|_{m+q, 2(m+q-1)!/(m-1)!}$ and on $\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{1 \leq k \leq m+q-1}$.

Since $\mathcal{E}^{0, p}=0$, we deduce from (4.3) that $\mathcal{E}^{q, p} \leq \frac{A_{1}(q, m)}{(p+1)^{m}}$ where $A_{1}(q, m):=$ $\frac{\left(C_{1} T(T+1) L_{f}^{2}\right)^{q}-1}{C_{1} T(T+1) L_{f}^{2}-1} K_{1}(q, m)$. Then, $\left(Y^{p, q}, Z^{p, q}\right)$ converges to $\left(Y^{q}, Z^{q}\right)$ when $p$ tends to $\infty$ in $\|(\cdot, \cdot)\|_{L^{2}}$; see (2.1) for the definition of the norm.

REMARK 4.12. We deduce from Proposition 4.11 that for all $T$ and $L_{f}$, we have $\lim _{p \rightarrow \infty} \mathcal{E}^{q, p}=0$. When $C_{1} T(T+1) L_{f}^{2}<1$, that is, for $T$ small enough, we also get $\lim _{p \rightarrow \infty} \lim _{q \rightarrow \infty} \mathcal{E}^{q, p}=0$.

Proof of Proposition 4.11. For the sake of clearness, we assume $d=1$. In the following, one notes $\Delta Y_{t}^{q, p}:=Y_{t}^{q, p}-Y_{t}^{q}, \Delta Z_{t}^{q, p}:=Z_{t}^{q, p}-Z_{t}^{q}$ and $\Delta f_{t}^{q, p}:=$ $f\left(t, Y_{t}^{q, p}, Z_{t}^{q, p}\right)-f\left(t, Y_{t}^{q}, Z_{t}^{q}\right)$. First, we deal with $\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p}\right|^{2}\right]$. From (3.4) and (3.5) we get

$$
\begin{aligned}
\Delta Y_{t}^{q+1, p}= & \mathbb{E}_{t}\left[\mathcal{C}_{p}\left(F^{q, p}\right)-F^{q}\right]-\int_{0}^{t} \Delta f_{s}^{q, p} d s \\
= & \mathbb{E}_{t}\left[\mathcal{C}_{p}(\xi)-\xi\right] \\
& +\mathbb{E}_{t}\left[\mathcal{C}_{p}\left(\int_{0}^{T} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right) d s\right)-\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s\right] \\
& -\int_{0}^{t} \Delta f_{s}^{q, p} d s
\end{aligned}
$$

We introduce $\pm \mathcal{C}_{p}\left(\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s\right)$ in the second conditional expectation. This leads to

$$
\begin{aligned}
\Delta Y_{t}^{q+1, p}= & \mathbb{E}_{t}\left[\mathcal{C}_{p}(\xi)-\xi\right]+\mathbb{E}_{t}\left[\mathcal{C}_{p}\left(\int_{0}^{T} \Delta f_{s}^{q, p} d s\right)\right] \\
& +\mathbb{E}_{t}\left[\int_{0}^{T} \mathcal{C}_{p}\left(f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right)-f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s\right] \\
& -\int_{0}^{t} \Delta f_{s}^{q, p} d s,
\end{aligned}
$$

where we have used the second property of Lemma 2.4 to rewrite the third term.

From the previous equation, we bound $\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p}\right|^{2}\right]$ by using Doob's inequality and the Lipschitz property of $f$

$$
\begin{aligned}
\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p}\right|^{2}\right] \leq & 16 \mathbb{E}\left[\left|\mathcal{C}_{p}(\xi)-\xi\right|^{2}\right]+16 \mathbb{E}\left[\left|\mathcal{C}_{p}\left(\int_{0}^{T} \Delta f_{s}^{q, p} d s\right)\right|^{2}\right] \\
& +16 T \int_{0}^{T} \mathbb{E}\left[\left|\mathcal{C}_{p}\left(f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right)-f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right|^{2}\right] d s \\
& +8 T L_{f}^{2} \int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p}\right|^{2}+\left|\Delta Z_{s}^{q, p}\right|^{2}\right] d s
\end{aligned}
$$

To bound the second expectation of the previous inequality, we use the first property of Lemma 2.4 and the Lispchitz property of $f$. Then we bring together this term with the last one to get

$$
\begin{align*}
\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p}\right|^{2}\right] \leq & 16 \mathbb{E}\left[\left|\mathcal{C}_{p}(\xi)-\xi\right|^{2}\right] \\
& +16 T \int_{0}^{T} \mathbb{E}\left[\left|\mathcal{C}_{p}\left(f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right)-f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right|^{2}\right] d s  \tag{4.4}\\
& +40 T L_{f}^{2} \int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p}\right|^{2}+\left|\Delta Z_{s}^{q, p}\right|^{2}\right] d s
\end{align*}
$$

Let us now upper bound $\mathbb{E}\left[\int_{0}^{T}\left|\Delta Z_{s}^{q+1, p}\right|^{2} d s\right]$. To do so, we use the Itô isometry $\mathbb{E}\left[\int_{0}^{T}\left|\Delta Z_{s}^{q+1, p}\right|^{2} d s\right]=\mathbb{E}\left[\left(\int_{0}^{T} \Delta Z_{s}^{q+1, p} d B_{s}\right)^{2}\right]$. Using the definitions (3.4)-(3.6) of $Z_{t}^{q+1}$ and $Z_{t}^{q+1, p}$ and the Clark-Ocone theorem leads to

$$
\begin{aligned}
\int_{0}^{T} \Delta Z_{s}^{q+1, p} d B_{s}= & F^{q}-\mathbb{E}\left(F^{q}\right)-\left(\mathcal{C}_{p}\left(F^{q, p}\right)-\mathbb{E}\left(\mathcal{C}_{p}\left(F^{q, p}\right)\right)\right) \\
= & Y_{T}^{q+1}+\int_{0}^{T} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right) d s \\
& -Y_{0}^{q+1}-\left(Y_{T}^{q+1, p}+\int_{0}^{T} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right) d s-Y_{0}^{q+1, p}\right)
\end{aligned}
$$

Rearranging this summation makes $\Delta Y_{T}^{q+1, p}-\left(\Delta Y_{0}^{q+1, p}\right)$ appear. We get

$$
\begin{align*}
& \mathbb{E}\left[\int_{0}^{T}\left|\Delta Z_{s}^{q+1, p}\right|^{2} d s\right] \\
& \quad \leq 6 \mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p}\right|^{2}\right]  \tag{4.5}\\
& \quad+6 T L_{f}^{2} \int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p}\right|^{2}+\left|\Delta Z_{s}^{q, p}\right|^{2}\right] d s
\end{align*}
$$

Since $\int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p}\right|^{2}+\left|\Delta Z_{s}^{q, p}\right|^{2}\right] d s \leq(T+1) \mathcal{E}^{q, p}$, by computing $7 \times(4.4)+$ (4.5) we obtain

$$
\begin{aligned}
\mathcal{E}^{q+1, p} \leq & 112 \mathbb{E}\left[\left|\mathcal{C}_{p}(\xi)-\xi\right|^{2}\right] \\
& +112 T \int_{0}^{T} \mathbb{E}\left[\left|\mathcal{C}_{p}\left(f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right)-f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right|^{2}\right] d s \\
& +286 T(T+1) L_{f}^{2} \mathcal{E}^{q, p} .
\end{aligned}
$$

Since $\xi$ and $f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)$ belong to $\mathbb{D}^{m, 2}\left(\xi\right.$ satisfies $\mathcal{H}_{m+q}^{1}, f \in C_{b}^{0, m+q-1, m+q-1}$ and $\left(Y^{q}, Z^{q}\right) \in \mathcal{S}^{m, \infty}$ [see Lemma 4.10)], Lemma 2.3 gives

$$
\begin{aligned}
\mathcal{E}^{q+1, p} \leq & \frac{112}{(p+1) \cdots(p+m)}\left\|D^{m} \xi\right\|_{\mathrm{L}^{2}\left(\Omega \times[0, T]^{m}\right)}^{2} \\
& +\frac{112 T}{(p+1) \cdots(p+m)}\left(\int_{0}^{T}\left\|D^{m} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right\|_{\mathrm{L}^{2}\left(\Omega \times[0, T]^{m}\right)}^{2} d s\right) \\
& +286 T(T+1) L_{f}^{2} \mathcal{E}^{q, p} .
\end{aligned}
$$

Since $\quad \int_{0}^{T}\left\|D^{m} f\left(s, Y_{s}^{q}, Z_{s}^{q}\right)\right\|_{\mathrm{L}^{2}\left(\Omega \times[0, T]^{m}\right)}^{2} d s \quad$ is bounded $\quad$ by $\quad C(T, m$, $\left.\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{k \leq m},\left\|\left(Y^{q}, Z^{q}\right)\right\|_{m, 2 m}^{2 m}\right)$, Lemma 4.10 gives the result.
4.3. Error due to the truncation of the basis. We are now interested in bounding the error between $\left(Y^{q, p}, Z^{q, p}\right)$ [defined by (3.5)] and ( $Y^{q, p, N}, Z^{q, p, N}$ ) [defined by (3.7)].

Before giving an upper bound for the error, we measure the error between $\mathcal{C}_{p}$ and $\mathcal{C}_{p}^{N}$ for a r.v. satisfying (4.1) when $r=p$.

REMARK 4.13. Let $r \in \mathbb{N}^{\star}, \xi$ satisfies $\mathcal{H}_{r+q}$ and $f \in C_{b}^{0, r+q-1, r+q-1}$. Then, for all integers $p$ and $q, I_{q, p}:=\int_{0}^{T} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right) d s$ satisfies (4.1); that is, for all multi-index $\alpha$ such that $|\alpha|=r$, we have

$$
\left|\mathbb{E}\left(D_{t_{1}, \ldots, t_{r}}^{\alpha} I_{q, p}\right)-\mathbb{E}\left(D_{s_{1}, \ldots, s_{r}}^{\alpha} I_{q, p}\right)\right| \leq K_{r}^{I_{q, p}}\left(\left(t_{1}-s_{1}\right)^{\beta_{q, p}}+\cdots+\left(t_{r}-s_{r}\right)^{\beta_{I_{q, p}}}\right),
$$

where $\beta_{I_{q, p}}=\frac{1}{2} \wedge \beta_{\xi}$ and $K_{r}^{I_{q, p}}$ depends on $K_{r}^{\xi},\|\xi\|_{r+q, 2(r+q-1)!/(r-1)!}, T$ and on $\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{1 \leq k \leq r+q-1}$.

We refer to Section A. 3 for the proof of Remark 4.13.
Lemma 4.14. Let $F$ denote a r.v. in $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right)$ satisfying (4.1) for $r=p$. We have

$$
\mathbb{E}\left(\left|\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}\right)(F)\right|^{2}\right) \leq\left(K_{p}^{F}\right)^{2}\left(\frac{T}{N}\right)^{2 \beta_{F}} \sum_{i=1}^{p} i^{2} \frac{T^{i}}{i!} \leq\left(K_{p}^{F}\right)^{2}\left(\frac{T}{N}\right)^{2 \beta_{F}} T(1+T) e^{T}
$$

where $K_{p}^{F}$ and $\beta_{F}$ are defined in Hypothesis 4.1.

We refer to Section A. 4 for the proof of the lemma.
Proposition 4.15. Assume that $\xi$ satisfies $\mathcal{H}_{p+q}$ and $f \in C_{b}^{0, p+q-1, p+q-1}$. We recall $\mathcal{E}^{q, p, N}:=\left\|\left(Y^{q, p}-Y^{q, p, N}, Z^{q, p}-Z^{q, p, N}\right)\right\|_{\mathrm{L}^{2}}^{2}$. We get

$$
\begin{equation*}
\mathcal{E}^{q+1, p, N} \leq C_{2} T(T+1) L_{f}^{2} \mathcal{E}^{q, p, N}+K_{2}(q, p)\left(\frac{T}{N}\right)^{1 \wedge 2 \beta_{\xi}}, \tag{4.6}
\end{equation*}
$$

where $C_{2}$ is a scalar and $K_{2}(q, p)$ depends on $K_{p}^{\xi}, T,\|\xi\|_{p+q, 2(p+q-1)!/(p-1)!}$ and on $\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{1 \leq k \leq p+q-1}$.

Since $\mathcal{E}^{0, p, N}=0$, we deduce from (4.6) that $\mathcal{E}^{q, p, N} \leq A_{2}(q, p)\left(\frac{T}{N}\right)^{1 \wedge 2 \beta_{\xi}}$, where $A_{2}(q, p):=K_{2}(q, p) T(T+1) e^{T} \frac{\left(C_{2} T(T+1) L_{f}^{2} q^{q}-1\right.}{C_{2} T(T+1) L_{f}^{2}-1}$. Then, $\left(Y^{p, q, N}, Z^{p, q, N}\right)$ converges to $\left(Y^{q, p}, Z^{q, p}\right)$ when $N$ tends to $\infty$ in $\|(\cdot, \cdot)\|_{L^{2}}$.

Proof of Proposition 4.15. For the sake of clarity, we assume $d=1$. In the following, we note $\Delta Y_{t}^{q, p, N}:=Y_{t}^{q, p, N}-Y_{t}^{q, p}, \Delta Z_{t}^{q, p, N}:=Z_{t}^{q, p, N}-Z_{t}^{q, p}$ and $\Delta f_{t}^{q, p, N}:=f\left(t, Y_{t}^{q, p, N}, Z_{t}^{q, p, N}\right)-f\left(t, Y_{t}^{q, p}, Z_{t}^{q, p}\right)$. First, we deal with $\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p, N}\right|^{2}\right]$. From (3.5) and (3.7) we get

$$
\Delta Y_{t}^{q+1, p, N}=\mathbb{E}_{t}\left[\mathcal{C}_{p}^{N}\left(F^{q, p, N}\right)-\mathcal{C}_{p}\left(F^{q, p}\right)\right]+\int_{0}^{t} \Delta f_{s}^{q, p, N} d s
$$

Following the same steps as in the proof of Proposition 4.11, we get

$$
\begin{aligned}
& \mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p, N}\right|^{2}\right] \\
& \leq
\end{aligned}
$$

Let us now upper bound $\mathbb{E}\left[\int_{0}^{T}\left|\Delta Z_{s}^{q+1, p, N}\right|^{2} d s\right]$. Following the same steps as in the proof of Proposition 4.11, we get

$$
\begin{aligned}
& \mathbb{E}\left[\int_{0}^{T}\left|\Delta Z_{s}^{q+1, p, N}\right|^{2} d s\right] \\
& \quad \leq 6 \mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p, N}\right|^{2}\right] \\
& \quad+6 T L_{f}^{2} \int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p, N}\right|^{2}+\left|\Delta Z_{s}^{q, p, N}\right|^{2}\right] d s
\end{aligned}
$$

Adding $7 \times(4.7)$ and (4.8) gives

$$
\begin{aligned}
\mathcal{E}^{q+1, p, N} \leq & 112 \mathbb{E}\left[\left|\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}\right)(\xi)\right|^{2}\right] \\
& +112 \mathbb{E}\left[\left|\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}\right)\left(\int_{0}^{T} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right) d s\right)\right|^{2}\right] \\
& +286 T(T+1) L_{f}^{2} \mathcal{E}^{q, p, N}
\end{aligned}
$$

Since $\xi$ and $I_{q, p}$ satisfy (4.1) (see Remarks 4.4 and 4.13), Lemma 4.14 gives

$$
\begin{aligned}
\mathcal{E}^{q+1, p, N} \leq & 112\left(\frac{T}{N}\right)^{2 \alpha_{\xi} \wedge 1} T(T+1) e^{T}\left(\left(K_{p}^{\xi}\right)^{2}+\left(K_{p}^{I_{q, p}}\right)^{2}\right) \\
& +286 T(T+1) L_{f}^{2} \mathcal{E}^{q, p, N}
\end{aligned}
$$

and (4.6) follows.
4.4. Error due to the Monte Carlo approximation. We are now interested in bounding the error between $\left(Y^{q, p, N}, Z^{q, p, N}\right)$ defined by (3.7) and ( $Y^{q, p, N, M}$, $\left.Z^{q, p, N, M}\right)$ defined by (3.11). $\mathcal{C}_{p}^{N, M}$ is defined by (3.9) and (3.10). In this section, we assume that the coefficients $\hat{d_{k}^{n}}$ are independent of the vector $\left(G_{1}, \ldots, G_{N}\right)$, which corresponds to the second approach proposed in Remark 3.2.

Before giving an upper bound for the error, we measure the error between $\mathcal{C}_{p}^{N}$ and $\mathcal{C}_{p}^{N, M}$ for a r.v. satisfying $\mathcal{H}_{p, N}^{3}$ (see Hypothesis 4.3).

Lemma 4.16. Let $F$ be a r.v. satisfying Hypothesis $\mathcal{H}_{p, N}^{3}$. We have

$$
\mathbb{E}\left(\left|\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}^{N, M}\right)(F)\right|^{2}\right)=\frac{1}{M} V_{p, N}(F)
$$

Moreover, we have $\mathbb{E}\left(\left|\mathcal{C}_{p}^{N, M}(F)\right|^{2}\right) \leq \mathbb{E}\left(|F|^{2}\right)+\frac{1}{M} V_{p, N}(F)$.
We refer to Section A. 5 for the proof of the lemma.
Proposition 4.17. Let $\xi$ satisfy Hypothesis $\mathcal{H}_{p, N}^{3}$ and $f$ be a bounded function. Let $\mathcal{E}^{q, p, N, M}:=\left\|\left(Y^{q, p, N}-Y^{q, p, N, M}, Z^{q, p, N}-Z^{q, p, N, M}\right)\right\|_{\mathrm{L}^{2}}^{2}$. We get

$$
\mathcal{E}^{q+1, p, N, M} \leq C_{3} T(T+1) L_{f}^{2} \mathcal{E}^{q, p, N, M}+\frac{K_{3}(q, p, N)}{M}
$$

where $C_{3}$ is a scalar and $K_{3}(q, p, N):=168\left(V_{p, N}(\xi)+T^{2}\|f\|_{\infty}^{2} \sum_{k=0}^{p}\binom{N}{k}\right)$.
Since $\mathcal{E}^{0, p, N, M}=0$, we deduce from the previous inequality that $\mathcal{E}^{q, p, N, M} \leq$ $\frac{A_{3}(q, p, N)}{M}$, where $A_{3}(q, p, N):=K_{3}(q, p, N) \frac{\left(C_{3} T(T+1) L_{f}^{2}\right)^{q}-1}{C_{3} T(T+1) L_{f}^{2}-1}$. Then $\left(Y^{p, q, N, M}\right.$, $\left.Z^{p, q, N, M}\right)$ converges to $\left(Y^{q, p, N}, Z^{q, p, N}\right)$ when $M$ tends to $\infty$ in $\|(\cdot, \cdot)\|_{L^{2}}$.

Proof of Proposition 4.17. For the sake of clarity, we assume $d=1$. In the following, note that $\Delta Y_{t}^{q, p, N, M}:=Y_{t}^{q, p, N, M}-Y_{t}^{q, p, N}, \Delta Z_{t}^{q, p, N, M}:=$ $Z_{t}^{q, p, N, M}-Z_{t}^{q, p, N}$ and $\Delta f_{t}^{q, p, N, M}:=f\left(t, Y_{t}^{q, p, N, M}, Z_{t}^{q, p, N, M}\right)-f\left(t, Y_{t}^{q, p, N}\right.$, $\left.Z_{t}^{q, p, N}\right)$. First, we deal with $\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p, N, M}\right|^{2}\right]$. From (3.7) and (3.11) we get

$$
\Delta Y_{t}^{q+1, p, N, M}=\mathbb{E}_{t}\left[\mathcal{C}_{p}^{N, M}\left(F^{q, p, N, M}\right)-\mathcal{C}_{p}^{N}\left(F^{q, p, N}\right)\right]+\int_{0}^{t} \Delta f_{s}^{q, p, N, M} d s
$$

By introducing $\pm \mathcal{C}_{p}^{N}\left(F^{q, p, N, M}\right)$ and by using Lemma 2.6, we obtain

$$
\begin{aligned}
\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p, N, M}\right|^{2}\right] \leq & 12 \mathbb{E}\left[\left|\left(\mathcal{C}_{p}^{N, M}-\mathcal{C}_{p}^{N}\right)\left(F^{q, p, N, M}\right)\right|^{2}\right] \\
& +12 \mathbb{E}\left(\left|F^{q, p, N, M}-F^{q, p, N}\right|^{2}\right) \\
& +6 T L_{f}^{2} \int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p, N, M}\right|^{2}+\left|\Delta Z_{s}^{q, p, N, M}\right|^{2}\right] d s
\end{aligned}
$$

From Lemma 4.16, we get $\mathbb{E}\left[\left|\left(\mathcal{C}_{p}^{N, M}-\mathcal{C}_{p}^{N}\right)\left(F^{q, p, N, M}\right)\right|^{2}\right] \leq \frac{2}{M}\left(V_{p, N}(\xi)+\right.$ $\left.V_{p, N}\left(\int_{0}^{T} f\left(\theta_{s}^{q, p, N, M}\right) d s\right)\right)$. Then

$$
\mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p, N, M}\right|^{2}\right]
$$

$$
\begin{align*}
\leq & \frac{24}{M}\left(V_{p, N}(\xi)+T^{2}\|f\|_{\infty}^{2} \sum_{k=0}^{p}\binom{N}{k}\right)  \tag{4.9}\\
& +30 T L_{f}^{2} \int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p, N, M}\right|^{2}+\left|\Delta Z_{s}^{q, p, N, M}\right|^{2}\right] d s
\end{align*}
$$

Let us now upper bound $\mathbb{E}\left[\int_{0}^{T}\left|\Delta Z_{s}^{q+1, p, N, M}\right|^{2} d s\right]$. Following the same steps as in the proof of Proposition 4.11, we get

$$
\begin{align*}
& \mathbb{E}\left[\int_{0}^{T}\left|\Delta Z_{s}^{q+1, p, N, M}\right|^{2} d s\right] \\
& \quad \leq 6 \mathbb{E}\left[\sup _{0 \leq t \leq T}\left|\Delta Y_{t}^{q+1, p, N, M}\right|^{2}\right]  \tag{4.10}\\
& \quad+6 T L_{f}^{2} \int_{0}^{T} \mathbb{E}\left[\left|\Delta Y_{s}^{q, p, N, M}\right|^{2}+\left|\Delta Z_{s}^{q, p, N, M}\right|^{2}\right] d s
\end{align*}
$$

Adding $7 \times(4.9)$ and (4.10) gives the result.
5. Numerical examples. The computations have been done on a PC INTEL Core 2 Duo P9600 2.53 GHz with 4Gb of RAM.

TABLE 1
Evolution of $\bar{Y}_{0}^{q, p, N, M}$ w.r.t. Picard's iterations, $M=10^{5}, N=20$ and CPU time

| Iterations | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | CPU time |
| :--- | :---: | :---: | :---: | :---: | :---: | ---: | ---: |
| $p=2$ | 1.656357 | 1.017117 | 1.237135 | 1.186691 | 1.195462 | 1.194256 | 14.06 |
| $p=3$ | 1.656357 | 1.012091 | 1.234398 | 1.183544 | 1.192367 | 1.191173 | 174.09 |

5.1. Nonlinear driver and path-dependent terminal condition. We consider the case $d=1, f(t, y, z)=\cos (y)$ and $\xi=\sup _{0 \leq t \leq 1} B_{t}$.

- Convergence in $p$. Tables 1 and 2 represent the evolution of $\bar{Y}_{0}^{q, p, N, M}$ and $\bar{Z}_{0}^{q, p, N, M}$ w.r.t $q$ (Picard's iteration index), when $p=2$ and $p=3$. We also give the CPU time needed to get $\bar{Y}_{0}^{6, p, N, M}$ and $\bar{Z}_{0}^{6, p, N, M}$. We fix $M=10^{5}$ and $N=20$. The seed of the generator is also fixed.

Note that the difference between the values of $\bar{Y}_{0}^{q, 2, N, M}$ and $\bar{Y}_{0}^{q, 3, N, M}$ (resp., $\bar{Z}_{0}^{q, 2, N, M}$ and $\bar{Z}_{0}^{q, 3, N, M}$ ) does not exceed $0.2 \%$ (resp., $0.6 \%$ ). This is due to the fast convergence of the algorithm in $p$. The CPU time is 12 times higher when $p=3$ than when $p=2$. Then, the use of order 3 in the chaos decomposition is not necessary. In the following, we take $p=2$.

- Convergence in $M$. Figure 1 illustrates the evolution of $\bar{Y}_{0}^{q, p, N, M}$ and $\bar{Z}_{0}^{q, p, N, M}$ w.r.t. $q$ when $p=2$ and $N=20$ for different values of $M$. The seed of the generator is random. When $M$ equals $10^{4}$ and $10^{5}$ the algorithm stabilizes after very few iterations. When $M=10^{3}$, there is no convergence.
- Convergence in $N$. Figure 2 illustrates the evolution of $\bar{Y}_{0}^{q, p, N, M}$ and $\bar{Z}_{0}^{q, p, N, M}$ w.r.t. $q$ when $p=2$ and $M=10^{5}$ for different values of $N$. The seed of the generator is random. The algorithm converges even when $N=10$, but $\bar{Y}_{0}^{6, p, 10, M}$ is quite below $\bar{Y}_{0}^{6, p, 40, M}$.
5.2. Linear driver-financial benchmark. We consider the case of pricing and hedging a discrete down and out barrier call option, that is, $f(t, y, z)=-r y$ and

TABLE 2
Evolution of $\bar{Z}_{0}^{q, p, N, M}$ w.r.t. Picard's iterations, $M=10^{5}, N=20$ and CPU time

| Iterations | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | CPU time |
| :--- | :---: | :---: | :---: | :---: | :---: | ---: | ---: |
| $p=2$ | 0.969128 | 0.249148 | 0.525273 | 0.459326 | 0.470069 | 0.469117 | 14.06 |
| $p=3$ | 0.969128 | 0.242977 | 0.523846 | 0.455827 | 0.466903 | 0.465939 | 174.09 |

FIG. 1. Evolution of $\bar{Y}_{0}^{q, p, N, M}$ and $\bar{Z}_{0}^{q, p, N, M}$ w.r.t. $q$ and $M$ when $\quad N=20$, $p=2-\xi=\sup _{0 \leq t \leq 1} B_{t}, f(t, y, z)=\cos (y)$.
$\xi:=\left(S_{T}-K\right)_{+} \mathbf{1}_{\forall n \in[0, N] S_{t_{n}} \geq L}$, where $S$ represents the Black-Scholes diffusion

$$
S_{t}=S_{0} e^{\left(r-(1 / 2) \sigma^{2}\right) t+\sigma W_{t}} \quad \forall t \in[0, T]
$$

The option parameters are $r=0.01, \sigma=0.2, T=1, K=0.9, L=0.85, S_{0}=1$ and $N=20$ ( $N$ is also the number of time discretizations of the chaos decomposition).

We can get a benchmark for $Y_{0}$ and $Z_{0}$ by using a variance reduction Monte Carlo method. For this set of parameters, the reference values are $Y_{0}=0.134267$ with a confidence interval $7.9468 e-05$ and $\delta_{0}=\frac{Z_{0}}{\sigma S_{0}}=0.8327$. We compare them with $\bar{Y}_{0}^{q, p, N, M}$ and $\frac{\bar{Z}_{0}^{q, p, N, M}}{\sigma S_{0}}$ when $N=20, p=2, q=5$ (we choose the first value of $q$ from which the algorithm has converged) for different values of $M$. Figure 3

FIG. 2. Evolution of $\bar{Y}_{0}^{q, p, N, M}$ and $\bar{Z}_{0}^{q, p, N, M}$ w.r.t. $N$ when $M=10^{5}, p=2-\xi=\sup _{0 \leq t \leq 1} B_{t}$, $f(t, y, z)=\cos (y)$.

FIG. 3. Evolution of $\bar{Y}_{0}^{q, p, N, M}$ and $\delta_{0}:=\frac{\bar{Z}_{0}^{q, p, N, M}}{\sigma S_{0}}$ w.r.t. $\log (M)$ when $N=20, p=2, q=5$, discrete down and out barrier call option.
represents the evolution of $\bar{Y}_{0}^{5, p, N, M}$ and $\delta_{0}^{5, p, N, M}$ w.r.t. $\log (M)$. Notice that for $M=10^{6}$ the computed values are very close to the reference values.
5.3. Nonlinear driver in dimension 5, financial benchmark. We consider the pricing and hedging of a put basket option in dimension 5, that is, $\xi=(K-$ $\left.\frac{1}{5} \sum_{i=1}^{5} S_{T}^{i}\right)_{+}$, where

$$
\forall i=1, \ldots, 5 \quad S_{t}^{i}=S_{0}^{i} e^{\left(\mu^{i}-\left(\sigma^{i}\right)^{2} / 2\right) t+\sigma^{i} B_{t}^{i}} .
$$

$\mu^{i}$ (resp., $\sigma^{i}$ ) represents the trend (resp., the volatility) of the $i$ th asset. $B=$ $\left(B^{1}, \ldots, B^{5}\right)$ is a 5-dimensional Brownian motion such that $\left\langle B^{i}, B^{j}\right\rangle_{t}=\rho t \mathbf{1}_{i \neq j}+$ $t \mathbf{1}_{i=j}$. We suppose that $\rho \in\left(-\frac{1}{4}, 1\right)$, which ensures that the matrix $C=\left(\rho \mathbf{1}_{i \neq j}+\right.$ $\left.\mathbf{1}_{i=j}\right)_{1 \leq i, j \leq 5}$ is positive definite. We also assume that the borrowing rate $R$ is higher than the bond rate $r$. In such a case, pricing and hedging the put basket option is equivalent to solving a BSDE with terminal condition $\xi$ and with driver $f$ defined by $f(t, y, z)=-r y-\theta \cdot z+(R-r)\left(y-\sum_{i=1}^{5}\left(\Sigma^{-1} z\right)_{i}\right)^{-}$, where $\theta:=\Sigma^{-1}(\mu-r \mathbf{1})(\mathbf{1}$ is the vector whose every component is one), and $\Sigma$ is the matrix defined by $\Sigma_{i j}=\sigma^{i} L_{i j}$ ( $L$ denote the lower triangular matrix involved in the Cholesky decomposition $C=L L^{*}$ ). We refer to [12], Example 1.1, for more details.

The option parameters are $r=0.02, R=0.1, T=1, K=95, \rho=0.1$, and for all $i=1, \ldots, 5, S_{0}^{i}=100, \mu_{0}^{i}=0.05$ and $\sigma_{0}^{i}=0.2$. Figure 4 represents the evolution of $\bar{Y}_{0}^{5, p, N, M}$, the approximated price at time 0 and the relative error on $\delta_{0}^{1}:=\frac{\left(\Sigma^{-1} \bar{Z}_{0}^{5, p, N, M}\right)^{1}}{S_{0}^{1}}$-the quantity of asset 1 to possess at time 0 -w.r.t. $\log (M)$. We compare our results with the ones obtained using the Algorithm proposed in [14] (cited here as reference values). The CPU time needed to compute price

Fig. 4. Evolution of $\bar{Y}_{0}^{q, p, N, M}$ and $\delta_{0}(1)$ w.r.t. $\log (M)$ when $N=20, p=2, q=5, d=5$, basket put option with different interest and borrowing rates.
and delta when $M=50,000$ and $N=20$ is 161 s . Notice that the convergence is very fast and quite accurate for $M=50,000$.

Conclusion. In this paper, we use Wiener chaos expansions together with the Picard procedure to compute the solution to (1.1). Once the chaos decomposition of $F^{q}$ is computed, we get explicit formulas for both conditional expectations and the Malliavin derivative of conditional expectations. This enables us to easily compute $\left(Y^{q}, Z^{q}\right)$. Numerically, we obtain fast and accurate results, which encourage us to extend these results to other type of BSDEs, like 2-BSDEs. It is also possible to couple these Wiener chaos expansions together with the dynamic programming approach. This will be the subject of a forthcoming publication.

## APPENDIX A: TECHNICAL RESULTS OF SECTION 4

In the following, for any regular r.v. $F \in \mathcal{F}_{T}, D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} F$ denotes $D_{t_{1}, \ldots, t_{0}}^{\left(l_{0}\right)} \times$ $\left(D_{t_{i}, s_{i+1}, \ldots, s_{i+l_{1}}}^{\left(l_{1}+1\right)} F-D_{s_{i}, \ldots, s_{i+l_{1}}}^{\left(l_{1}+1\right)} F\right)$.
A.1. Proof of Remark 4.5. Before proving Remark 4.5, we prove the following lemma.

Lemma A.1. Let $X$ be the $\mathbb{R}^{n}$-valued process solution of

$$
X_{t}=x+\int_{0}^{t} b\left(s, X_{s}\right) d s+\int_{0}^{t} \sigma\left(s, X_{s}\right) d B_{s}
$$

where $B$ is a d-dimensional Brownian motion and $b:[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ and $\sigma:[0, T] \times \mathbb{R}^{n} \rightarrow \mathbb{R}^{n \times d}$ are two $C^{0, m}$ functions uniformly lipschitz, w.r.t. $x$ and Hölder continuous of parameter $\frac{1}{2}$ w.r.t. $t$, with linear growth in $x$ (of constant $K$ ) and with bounded derivatives. Then:

- $\forall l \leq m, \forall j \geq 2$ we have

$$
\begin{equation*}
M_{l}^{j}:=\sup _{t_{1} \leq \cdots \leq t_{l}} \mathbb{E}\left(\sup _{r \in\left[t_{l}, T\right]}\left|D_{t_{1}, \ldots, t_{l}}^{(l)} X_{r}\right|^{j}\right)<\infty \tag{A.1}
\end{equation*}
$$

the upper bound depends on $\left(\left\|b^{\left(l^{\prime}\right)}\right\|_{\infty}\right)_{l^{\prime} \leq l},\left(\left\|\sigma^{\left(l^{\prime}\right)}\right\|_{\infty}\right)_{l^{\prime} \leq l}, x$ and $K$,

- $\forall j \geq 2, \forall i \in\{1, \ldots, m\}, \forall l_{0} \leq i-1, \forall l_{1} \leq m-i$, we have
(A.2) $\sup _{t_{1} \leq \cdots \leq t_{0}} \sup _{s_{i+1} \leq \cdots \leq s_{i+l_{1}}} \mathbb{E}\left(\sup _{r \in\left[s_{i+l_{1}}, T\right]}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} X_{r}\right|^{j}\right)<k_{l}^{X}(j)\left(t_{i}-s_{i}\right)^{j / 2}$,
where $l:=l_{0}+l_{1}+1$ and $k_{l}^{X}$ depends on $T,\left(M_{l^{\prime}}^{j^{\prime}}\right)_{l^{\prime} \leq l, j^{\prime} \leq l j},\left(\left\|b^{\left(l^{\prime}\right)}\right\|_{\infty}\right)_{l^{\prime} \leq l}$, and on $\left(\left\|\sigma^{\left(l^{\prime}\right)}\right\|_{\infty}\right)_{l^{\prime} \leq l}$.

Proof of Lemma A.1. The first point is proved in [19], Theorem 2.2.2. For the sake of clarity, we prove the second result for $d=1$. We also assume that the vectors $\left(t_{1}, \ldots, t_{n}\right)$ and $\left(s_{1}, \ldots, s_{n}\right)$ are such that $0 \leq s_{1} \leq t_{1} \leq s_{2} \leq \cdots \leq s_{n} \leq t_{n} \leq$ $T$. We do it by induction on $l_{0}$ and $l_{1}$. We detail the case $b$ and $\sigma$ only depending on $x$ and do the proof for $l_{0}=l_{1}=0$ and $l_{0}=0, l_{1}=1$. We recall that under these hypotheses on $b$ and $\sigma$, we have $\forall l \leq m$

$$
\sup _{t_{1} \leq \cdots \leq t_{l}} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{(l)}\left(X_{t_{l+1}}-X_{s_{l+1}}\right)\right|^{j}\right] \leq C\left(t_{l+1}-s_{l+1}\right)^{j / 2},
$$

where $C$ depends on $T, j,\left(M_{l^{\prime}}^{j^{\prime}}\right)_{l^{\prime} \leq l, j^{\prime} \leq l j}$ and on $\left(\left\|b^{\left(j^{\prime}\right)}\right\|_{\infty}\right)_{j^{\prime} \leq j}$, and on $\left(\left\|\sigma^{\left(j^{\prime}\right)}\right\|_{\infty}\right)_{j^{\prime} \leq j}$.

Case $l_{0}=l_{1}=0$. We have

$$
\begin{aligned}
D_{t_{n}} X_{r}= & \int_{t_{n}}^{r} b^{\prime}\left(X_{u}\right) D_{t_{n}} X_{u} d u+\sigma\left(X_{t_{n}}\right) \\
& +\int_{t_{n}}^{r} \sigma^{\prime}\left(X_{u}\right) D_{t_{n}} X_{u} d B u
\end{aligned}
$$

Then

$$
\begin{aligned}
\Delta_{n} X_{r}:= & D_{t_{n}} X_{r}-D_{s_{n}} X_{r} \\
= & \int_{t_{n}}^{r} b^{\prime}\left(X_{u}\right) \Delta_{n} X_{u} d u-\int_{s_{n}}^{t_{n}} b\left(X_{u}\right) D_{s_{n}}\left(X_{u}\right) d u \\
& +\sigma\left(X_{t_{n}}\right)-\sigma\left(X_{s_{n}}\right)+\int_{t_{n}}^{r} \sigma^{\prime}\left(X_{u}\right) \Delta_{n} X_{u} d B u \\
& -\int_{s_{n}}^{t_{n}} \sigma^{\prime}\left(X_{u}\right) D_{s_{n}}\left(X_{u}\right) d B u .
\end{aligned}
$$

In the following, $C$ denotes a generic constant depending only on $T$ and $j$, and $L_{\sigma}$ denotes the Lipschitz contant of $\sigma$.

$$
\begin{aligned}
& \left|\Delta_{n} X_{r}\right|^{j} \leq C\left(\left\|b^{\prime}\right\|_{\infty}^{j} \int_{t_{n}}^{r}\left|\Delta_{n} X_{u}\right|^{j} d u+\left(t_{n}-s_{n}\right)^{j-1}\left\|b^{\prime}\right\|_{\infty}^{j} \int_{s_{n}}^{t_{n}}\left|D_{s_{n}}\left(X_{u}\right)\right|^{j} d u\right. \\
& +L_{\sigma}^{j}\left|X_{t_{n}}-X_{s_{n}}\right|^{j}+\left|\int_{t_{n}}^{r} \sigma^{\prime}\left(X_{u}\right) \Delta_{n} X_{u} d B u\right|^{j} \\
& \left.+\left|\int_{s_{n}}^{t_{n}} \sigma^{\prime}\left(X_{u}\right) D_{s_{n}}\left(X_{u}\right) d B u\right|^{j}\right) .
\end{aligned}
$$

We introduce $\Psi_{n}^{0, j}(T):=\mathbb{E}\left[\sup _{r \in\left[t_{n}, T\right]}\left|\Delta_{n} X_{r}\right|^{j}\right]$. Doob's inequality and the Burkhölder-Davis-Gundy inequality lead to

$$
\begin{aligned}
& \Psi_{n}^{0, j}(T) \leq C\left(\left(\left\|b^{\prime}\right\|_{\infty}^{j}+\left\|\sigma^{\prime}\right\|_{\infty}^{j}\right) \int_{t_{n}}^{T} \Psi_{n}^{0, j}(u) d u+\left\|b^{\prime}\right\|_{\infty}^{j} M_{1}^{j}\left(t_{n}-s_{n}\right)^{j}\right. \\
&\left.+\left(L_{\sigma}^{j}+\left\|\sigma^{\prime}\right\|_{\infty}^{j} M_{1}^{j}\right)\left|t_{n}-s_{n}\right|^{j / 2}\right)
\end{aligned}
$$

Gronwall's lemma yields the result.
Case $l_{0}=0, l_{1}=1$. We consider $\Delta_{n-1} D_{t_{n}} X_{r}=D_{t_{n-1}, t_{n}} X_{r}-D_{s_{n-1}, t_{n}} X_{r}$. We have

$$
\begin{aligned}
D_{t_{n-1}, t_{n}} X_{r}= & \int_{t_{n}}^{r} b^{\prime \prime}\left(X_{u}\right) D_{t_{n-1}} X_{u} D_{t_{n}} X_{u}+b^{\prime}\left(X_{u}\right) D_{t_{n-1}, t_{n}} X_{u} d u \\
& +\sigma^{\prime}\left(X_{t_{n}}\right) D_{t_{n-1}} X_{t_{n}} \\
& +\int_{t_{n}}^{r} \sigma^{\prime \prime}\left(X_{u}\right) D_{t_{n-1}} X_{u} D_{t_{n}} X_{u}+\sigma^{\prime}\left(X_{u}\right) D_{t_{n-1}, t_{n}} X_{u} d B u .
\end{aligned}
$$

Then

$$
\begin{aligned}
\Delta_{n-1} D_{t_{n}} X_{r}= & \int_{t_{n}}^{r} b^{\prime \prime}\left(X_{u}\right) \Delta_{n-1} X_{u} D_{t_{n}} X_{u}+b^{\prime}\left(X_{u}\right) \Delta_{n-1} D_{t_{n}} X_{u} d u \\
& +\sigma^{\prime}\left(X_{t_{n}}\right) \Delta_{n-1} X_{t_{n}} \\
& +\int_{t_{n}}^{r} \sigma^{\prime \prime}\left(X_{u}\right) \Delta_{n-1} X_{u} D_{t_{n}} X_{u}+\sigma^{\prime}\left(X_{u}\right) \Delta_{n-1} D_{t_{n}} X_{u} d B u .
\end{aligned}
$$

Doob's inequality and the Burkhölder-Davis-Gundy inequality lead to

$$
\begin{aligned}
& \mathbb{E}\left[\sup _{r \in\left[t_{n}, T\right]}\left|\Delta_{n-1} D_{t_{n}} X_{r}\right|^{j}\right] \\
& \quad \leq C\left(\int_{t_{n}}^{T}\left\|b^{\prime \prime}\right\|_{\infty}^{j} \mathbb{E}\left[\left|\Delta_{n-1} X_{u}\right|^{j}\left|D_{t_{n}} X_{u}\right|^{j}\right]\right. \\
& \quad+\left\|b^{\prime}\right\|_{\infty}^{j} \mathbb{E}\left[\left|\Delta_{n-1} D_{t_{n}} X_{u}\right|^{j}\right] d u
\end{aligned}
$$

$$
\begin{aligned}
& +\left\|\sigma^{\prime}\right\|_{\infty}^{j} \mathbb{E}\left[\left|\Delta_{n-1} X_{t_{n}}\right|^{j}\right] \\
& \left.+\int_{t_{n}}^{T}\left\|\sigma^{\prime \prime}\right\|_{\infty}^{j} \mathbb{E}\left[\left|\Delta_{n-1} X_{u}\right|^{j}\left|D_{t_{n}} X_{u}\right|^{j}\right]+\left\|\sigma^{\prime}\right\|_{\infty}^{j} \mathbb{E}\left[\left|\Delta_{n-1} D_{t_{n}} X_{u}\right|^{j}\right] d u\right)
\end{aligned}
$$

We introduce $\Psi_{n-1}^{1, j}(T):=\sup _{t_{n} \leq T} \mathbb{E}\left[\sup _{r \in\left[t_{n}, T\right]}\left|\Delta_{n-1} D_{t_{n}} X_{r}\right|^{j}\right]$. The CauchySchwarz inequality yields

$$
\begin{aligned}
& \Psi_{n-1}^{1, j}(T) \leq C\left(\left(\left\|b^{\prime}\right\|_{\infty}^{j}+\left\|\sigma^{\prime}\right\|_{\infty}^{j}\right) \int_{t_{n}}^{T} \Psi_{n-1}^{1, j}(u) d u\right. \\
& +\left(\left\|b^{\prime \prime}\right\|_{\infty}^{j}+\left\|\sigma^{\prime \prime}\right\|_{\infty}^{j}\right)\left(M_{1}^{2 j}\right)^{1 / 2}\left(\Psi_{n-1}^{0,2 j}(T)\right)^{1 / 2} \\
& \\
& \left.\quad+\left\|\sigma^{\prime}\right\|_{\infty}^{j} \Psi_{n-1}^{0, j}(T)\right)
\end{aligned}
$$

Since $\Psi_{n-1}^{0,2 j}(T) \leq K\left(t_{n-1}-s_{n-1}\right)^{j}$, and $\Psi_{n-1}^{0, j}(T) \leq K\left(t_{n-1}-s_{n-1}\right)^{j / 2}$, Gronwall's lemma ompletes the proof.

PROOF OF REMARK 4.5. We prove the result for $d=1$. We first prove that $g\left(X_{T}\right)$ belongs to $\mathcal{D}^{m, j}$ for all $j \geq 2$, that is,

$$
\left\|g\left(X_{T}\right)\right\|_{m, j}^{j}=\sum_{l \leq m} \sum_{t_{1}, \ldots, t_{l}} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{(l)} g\left(X_{T}\right)\right|^{j}\right]<\infty
$$

$D_{t_{1}, \ldots, t_{l}}^{(l)} g\left(X_{T}\right)$ contains a sum of terms of type $g^{(k)}\left(X_{T}\right) \prod_{i=1}^{k} D_{t}^{\left(j_{i}\right)} X_{T}$, where $k$ varies in $\{1, \ldots, l\},|j|_{1}=l$ and $a(j)=k[a(j)$ denotes the number of nonzero components of $j$ ]. Since $g \in C_{p}^{\infty}$, and $X$ satisfies (A.1), we get the result.

Let us now prove that $g\left(X_{T}\right)$ satisfies $\mathcal{H}_{m}^{2} . D_{t}^{\left(l_{0}\right)} \Delta_{t_{i}, s_{i}} D_{s}^{\left(l_{1}\right)} g\left(X_{T}\right)$ contains a sum of terms of type $g^{(k)}\left(X_{T}\right) \prod_{i=1}^{k-1}\left(D_{t}^{\left(j_{i}\right)} X_{T}\right) D_{t}^{\left(l_{0}^{\prime}\right)} \Delta_{t_{i}, s_{i}} D_{s}^{\left(l_{1}^{\prime}\right)} X_{T}$, where $k$ varies in $\{1, \ldots, l\},|j|_{1}=l-1-l_{0}^{\prime}-l_{1}^{\prime}, a(j)=k-1, l_{0}^{\prime} \leq l_{0}$ and $l_{1}^{\prime} \leq l_{1}$. Then, since $g \in C_{p}^{\infty}, X$ satisfies (A.1) and (A.2), we get $g\left(X_{T}\right)$ satisfies $\mathcal{H}_{m}^{2}$, with $\beta_{g\left(X_{T}\right)}=\frac{1}{2}$ and $k_{l}^{g\left(X_{T}\right)}$ depends on $\left(\left\|g^{\left(l^{\prime}\right)}\right\|_{\infty}\right)_{l^{\prime} \leq l}$, on $\left(M_{l^{\prime}}^{j^{\prime}}\right)_{l^{\prime} \leq l, j^{\prime} \leq l j}$ and on $K_{l}^{X}$.

It remains to prove that $g\left(X_{T}\right)$ satisfies $\mathcal{H}_{p, N}^{3} \cdot \mathbb{V}\left(g\left(X_{T}\right)\right)$ is bounded by $\mathbb{E}\left(\left(g\left(X_{T}\right)\right)^{2}\right)$. Since $g \in C_{p}^{\infty}$ and $X$ satisfies $\mathbb{E}\left(\left|X_{T}\right|^{j}\right)<\infty$ for all $j$, we get that $\mathbb{V}\left(g\left(X_{T}\right)\right)$ is bounded. We prove that $\mathbb{V}\left(g\left(X_{T}\right) \prod_{i=1}^{N} K_{n_{i}}\left(G_{i}\right)\right)$ is bounded by the same way.
A.2. Proof of Lemma 4.10. We complete the proof for $d=1$. We prove by induction that $\forall q^{\prime} \leq q,\left(Y^{q^{\prime}}, Z^{q^{\prime}}\right)$ belongs to $\mathcal{S}^{m, \infty}$, that is, $\forall j \geq 2$

$$
\begin{aligned}
& \left\|\left(Y^{q^{\prime}}, Z^{q^{\prime}}\right)\right\|_{m, j}^{j} \\
& \quad=\sum_{1 \leq l \leq m} \sup _{t_{1} \leq \cdots \leq t_{l}}\left\{\mathbb{E}\left[\sup _{t_{l} \leq r \leq T}\left|D_{t_{1}, \ldots, t_{l}}^{(l)} Y_{r}^{q^{\prime}}\right|^{j}\right]+\int_{t_{l}}^{T} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{(l)} Z_{r}^{q^{\prime}}\right|^{j}\right] d r\right\}<\infty .
\end{aligned}
$$

Using (3.4) gives

$$
D_{t_{1}, \ldots, t_{l}}^{(l)} Y_{r}^{q^{\prime}}=\mathbb{E}_{r}\left[D_{t_{1}, \ldots, t_{l}}^{(l)} F^{q^{\prime}-1}\right]-\int_{t_{l}}^{r} D_{t_{1}, \ldots, t_{l}}^{(l)} f\left(\theta_{u}^{q^{\prime}-1}\right) d u
$$

where $\theta_{u}^{q^{\prime}-1}:=\left(u, Y_{u}^{q^{\prime}-1}, Z_{u}^{q^{\prime}-1}\right)$.
Using the definition of $F^{q^{\prime}-1}$ and applying Doob's inequality leads to

$$
\mathbb{E}\left[\sup _{t_{l} \leq r \leq T}\left|D_{t_{1}, \ldots, t_{l}}^{(l)} Y_{r}^{q^{\prime}}\right|^{j}\right] \leq C\left(\mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{(l)} \xi\right|^{j}\right]+\mathbb{E}\left(\int_{t_{l}}^{T}\left|D_{t_{1}, \ldots, t_{l}}^{(l)} f\left(\theta_{u}^{q^{\prime}-1}\right)\right|^{j} d u\right)\right),
$$

where $C$ is a generic constant depending on $T$ and $j$.
$D_{t_{1}, \ldots, t_{l}}^{(l)} f\left(\theta_{u}^{q^{\prime}-1}\right)$ contains a sum of terms of type $\partial_{y}^{l_{0}} \partial_{z}^{l_{1}} f\left(\theta_{u}^{q^{\prime}-1}\right) \prod_{i=1}^{l_{0}} D_{t}^{j_{i}} \times$ $Y_{u}^{q^{\prime}-1} \prod_{i=1}^{l_{1}} D_{t}^{k_{i}} Z_{u}^{q^{\prime}-1}$, where $|j|_{1}+|k|_{1}=l, a(j)=l_{0}, a(k)=l_{1}$ and $l_{0}+l_{1} \leq l$. Then Hölder's inequality gives

$$
\begin{align*}
& \mathbb{E}\left(\int_{t_{l}}^{T}\left|D_{t_{1}, \ldots, t_{l}}^{(l)} f\left(\theta_{u}^{q^{\prime}-1}\right)\right|^{j} d u\right) \\
& \quad \leq C\left(\sum_{k=1}^{l}\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}^{j}\right)\left\|\left(Y^{q^{\prime}-1}, Z^{q^{\prime}-1}\right)\right\|_{l, l j}^{l j} \tag{A.3}
\end{align*}
$$

and

$$
\begin{align*}
& \sum_{1 \leq l \leq m} \sup _{t_{1} \leq \cdots \leq t_{l}} \mathbb{E}\left[\sup _{t_{l} \leq r \leq T}\left|D_{t_{1}, \ldots, t_{l}}^{(l)} Y_{r}^{q^{\prime}}\right|^{j}\right] \\
& \quad \leq C\left(\|\xi\|_{m, j}^{j}+\sum_{l=1}^{m}\left(\sum_{k=1}^{l}\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}^{j}\right)\left\|\left(Y^{q^{\prime}-1}, Z^{q^{\prime}-1}\right)\right\|_{l, l j}^{l j}\right) . \tag{A.4}
\end{align*}
$$

From (3.4), we get $D_{t_{1}, \ldots, t_{l}}^{(l)} Z_{r}^{q^{\prime}}=\mathbb{E}_{r}\left[D_{t_{1}, \ldots, t_{l}, r}^{(l+1)} \xi+\int_{r}^{T} D_{t_{1}, \ldots, t_{l}, r}^{(l+1)} f\left(\theta_{u}^{q^{\prime}-1}\right) d u\right]$.
Then

$$
\begin{aligned}
& \int_{t_{l}}^{T} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{(l)} Z_{r}^{q^{\prime}}\right|^{j}\right] d r \\
& \quad \leq C\left(\int_{t_{l}}^{T} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}, r}^{(l+1)} \xi\right|^{j}\right] d r+\int_{t_{l}}^{T} \mathbb{E}\left(\left|\int_{r}^{T} D_{t_{1}, \ldots, t_{l}, r}^{(l+1)} f\left(\theta_{u}^{q^{\prime}-1}\right) d u\right|^{j}\right) d r\right)
\end{aligned}
$$

Using (A.3) yields

$$
\begin{aligned}
& \sum_{1 \leq l \leq m} \sup _{t_{1} \leq \cdots \leq t_{l}} \int_{t_{l}}^{T} \mathbb{E}\left[\left|D_{t_{1}, \ldots, t_{l}}^{(l)} Z_{r}^{q^{\prime}}\right|^{j}\right] d r \\
& \quad \leq C\left(\|\xi\|_{m+1, j}^{j}+\sum_{l=1}^{m}\left(\sum_{k=1}^{l}\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}^{j}\right)\left\|\left(Y^{q^{\prime}-1}, Z^{q^{\prime}-1}\right)\right\|_{(l+1),(l+1) j}^{(l+1) j}\right)
\end{aligned}
$$

Combining this equation with (A.4) gives

$$
\begin{aligned}
& \left\|\left(Y^{q^{\prime}}, Z^{q^{\prime}}\right)\right\|_{m, j}^{j} \\
& \quad \leq C\left(\|\xi\|_{m+1, j}^{j}+\left(\sum_{k=1}^{m}\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}^{j}\right) \sum_{l=1}^{m}\left\|\left(Y^{q^{\prime}-1}, Z^{q^{\prime}-1}\right)\right\|_{(l+1),(l+1) j}^{(l+1) j}\right) .
\end{aligned}
$$

Iterating this inequality yields the result. We prove that $\forall q^{\prime} \leq q,\left(Y^{q^{\prime}, p}, Z^{q^{\prime}, p}\right)$ belongs to $\mathcal{S}^{m, \infty}$ in the same way. In this case, the generic constant $C$ depends on $T, j$ and $p$, since we need to use the first part of Lemma 2.4 to upper bound $\mathbb{E}\left(\left|\mathcal{C}_{p-l}\left(D_{t}^{(l)} F^{(q-1, p)}\right)\right|^{j}\right)$.
A.3. Proof of Remark 4.13. For the sake of clarity, we assume that $\forall i \leq r$, $t_{i-1} \leq s_{i} \leq t_{i}$ and $d=1$. Then we show that if $\xi$ satisfies $\mathcal{H}_{r+q}$ and $f \in$ $C_{b}^{0, r+q-1, r+q-1}$, then $I_{q, p}:=\int_{0}^{T} f\left(s, Y_{s}^{q, p}, Z_{s}^{q, p}\right) d s$ satisfies

$$
\left|\mathbb{E}\left(D_{t_{1}, \ldots, t_{r}}^{(r)} I_{q, p}\right)-\mathbb{E}\left(D_{s_{1}, \ldots, s_{r}}^{(r)} I_{q, p}\right)\right| \leq K_{r}^{I_{q, p}}\left(\left(t_{1}-s_{1}\right)^{\beta_{q, p}}+\cdots+\left(t_{r}-s_{r}\right)^{\beta_{I_{q, p}}}\right) .
$$

Since $I_{0, p}=0$, we deal with the case $q \geq 1$. Since we have $D_{t_{1}, \ldots, t_{r}}^{(r)} I_{q, p}-$ $D_{s_{1}, \ldots, s_{r}}^{(r)} I_{q, p}=\sum_{i=1}^{r} D_{t}^{(i-1)} \Delta_{i} D_{s}^{(r-i)} I_{q, p}$, it is enough to prove that $\mathbb{E}\left(D_{t}^{(i-1)} \times\right.$ $\left.\Delta_{i} D_{s}^{(r-i)} I_{q, p}\right) \leq K_{i}\left(t_{i}-s_{i}\right)^{\beta_{I q, p}}$ (we refer to the beginning of Section A for the definition of $\left.D_{t}^{(i-1)} \Delta_{i} D_{s}^{(r-i)} F\right)$.

We introduce $\theta_{u}^{q, p}=\left(u, Y_{u}^{q, p}, Z_{u}^{q, p}\right)$, two vectors $j$ and $m$, and four integers $k_{0}, k_{1}, l_{0}$ and $l_{1}$ such that $l_{0} \leq i-1, l_{1} \leq r-i,|j|_{1}+|m|_{1}=r-1-l_{0}-l_{1}$ and $k_{0}+k_{1} \leq r$. If $i<r, D_{t}^{(i-1)} \Delta_{i} D_{s}^{(r-i)} I_{q, p}$ contains a sum of terms of type

$$
\int_{s_{r}}^{T} \partial_{y}^{k_{0}} \partial_{z}^{k_{1}} f\left(\theta_{u}^{q, p}\right) \prod_{i=1}^{k_{0}-1} D_{t s}^{j_{i}} Y_{u}^{q, p} \prod_{i=1}^{k_{1}} D_{t s}^{m_{i}} Z_{u}^{q, p}\left(D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{u}^{q, p}\right) d u
$$

where $a(j)=k_{0}-1[a(j)$ denotes the number of nonzero components of $j]$ and $a(m)=k_{1}$ and of type

$$
\int_{s_{r}}^{T} \partial_{y}^{k_{0}} \partial_{z}^{k_{1}} f\left(\theta_{u}^{q, p}\right) \prod_{i=1}^{k_{0}} D_{t s}^{j_{i}} Y_{u}^{q, p} \prod_{i=1}^{k_{1}-1} D_{t s}^{m_{i}} Z_{u}^{q, p}\left(D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Z_{u}^{q, p}\right) d u
$$

where $a(j)=k_{0}, a(m)=k_{1}-1$. By using the Cauchy-Schwarz inequality, we get that $\mathbb{E}\left[D_{t}^{(i-1)} \Delta_{i} D_{s}^{(r-i)} I_{q, p}\right]$ is bounded by $\left\|\partial_{\mathrm{sp}}^{k_{0}+k_{1}} f\right\|_{\infty}$

$$
\times \mathbb{E}\left(\int_{s_{r}}^{T} \prod_{i=1}^{k_{0}-1}\left(D_{t s}^{j_{i}} Y_{u}^{q, p}\right)^{2} \prod_{i=1}^{k_{1}}\left(D_{t s}^{m_{i}} Z_{u}^{q, p}\right)^{2} d u \int_{s_{r}}^{T}\left(D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{u}^{q, p}\right)^{2} d u\right)^{1 / 2}
$$

(and the same type of term in $D_{t}^{l_{0}} \Delta_{i} D_{s}^{\left(l_{1}\right)} Z_{u}^{q, p}$ ) which leads to

$$
\begin{align*}
& \mathbb{E}\left[D_{t}^{(i-1)} \Delta_{i} D_{s}^{(r-i)} I_{q, p}\right] \\
& \leq  \tag{A.5}\\
& \quad C\left(T,\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{k \leq r},\left\|\left(Y^{q, p}, Z^{q, p}\right)\right\|_{r-1,2(r-1)}\right) \\
& \quad \times \sum_{l_{0}=0}^{i-1} \sum_{l_{1}=0}^{r-i} \sqrt{\left(D_{t}^{\left(l_{0}\right)} \Delta_{i}^{q, p} D_{s}^{\left(l_{1}\right)}\right)_{2}}
\end{align*}
$$

where $\left(D_{t}^{\left(l_{0}\right)} \Delta_{i}^{q, p} D_{s}^{\left(l_{1}\right)}\right)_{j}:=\mathbb{E}\left[\sup _{s_{r} \leq u \leq T}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{u}^{q, p}\right|^{j}\right]+\mathbb{E}\left(\int_{s_{r}}^{T} \mid D_{t}^{\left(l_{0}\right)} \times\right.$ $\left.\left.\Delta_{i} D_{s}^{\left(l_{1}\right)} Z_{u}^{q, p}\right|^{2} d u\right)^{j / 2}$. If $i=r, D_{t}^{(r-1)} \Delta_{i} I_{q, p}$ contains the same type of integrals between $s_{r}$ and $T$ plus an integral between $s_{r}$ and $t_{r}$, which is bounded by $C\left(T,\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{k \leq r},\left\|\left(Y^{q, p}, Z^{q, p}\right)\right\|_{r, 2 r}\right)\left(t_{r}-s_{r}\right)$. Then, since $\left(Y^{q, p}, Z^{q, p}\right) \in$ $\mathcal{S}^{r, \infty}$ and $f \in C_{b}^{0, r+q-1, r+q-1}$, it remains to take the supremum over $t_{1}, \ldots, t_{l_{0}}$, $s_{i+1}, \ldots, s_{i+l_{1}}$ in (A.5) and to apply Lemma A. 2 to end the proof. $K_{i}$ depends on $\|\xi\|_{r+q, 2(r+q-1)!/(r-1)!},\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{1 \leq k \leq r+q-1}, T$ and $K_{r}^{q, p}:=\sup _{l \leq r} k_{l}^{q, p}$ (where $k_{l}^{q, p}$ is defined in Lemma A.2).

Lemma A.2. Assume $\xi$ satisfies $\mathcal{H}_{r+q}^{2}$ and $f \in \mathcal{C}_{b}^{0, r+q-1, r+q-1}$. Then $\forall i \in$ $\{1, \ldots, r\}, \forall l_{0} \leq i-1, \forall l_{1} \leq r-i$ and $\forall j \geq 2$

$$
\sup _{t_{1} \leq \cdots \leq t_{0} s_{i+1} \leq \cdots \leq s_{i+l_{1}}} \sup _{t} \mathbb{E}\left[\left(D_{t}^{\left(l_{0}\right)} \Delta_{i}^{q, p} D_{s}^{\left(l_{1}\right)}\right)_{j}\right] \leq k_{l}^{q, p}\left(t_{i}-s_{i}\right)^{j\left(1 / 2 \wedge \beta_{\xi}\right)}
$$

where $l=l_{0}+l_{1}+1$ and $k_{l}^{q, p}$ depends on $k_{l}^{\xi}, T,\|\xi\|_{l+q-1,(l+q-2)!/(l-1)!j}$ and on $\left(\left\|\partial_{\text {sp }}^{k} f\right\|_{\infty}\right)_{1 \leq k \leq l+q-2}$.

Proof. We complete the proof by induction on $q$. We distinguish cases $l_{1}>0$ and $l_{1}=0$. We first consider $l_{1}>0$. Let $u$ be in $\left[s_{r}, T\right]$ and $l \leq p$ (if $l>p$, the first term on the right-hand side of the following equality vanishes). From (3.5) and Lemma 2.4, we get $D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{u}^{q, p}=\mathbb{E}_{u}\left[\mathcal{C}_{p-r}\left(D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} F^{q-1, p}\right)\right]-$ $\int_{s_{i+l_{1}}}^{u} D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{v}^{q-1}\right) d v$. Using the definition of $F^{q-1, p}$ [see (3.5)], Doob's inequality and Lemma 2.4 yields

$$
\begin{align*}
& \mathbb{E}\left[\sup _{u \in\left[s_{r}, T\right]}\left(D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{u}^{q, p}\right)^{j}\right] \\
& \leq C\left(\mathbb{E}\left[\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} \xi\right|^{j}\right]\right.  \tag{A.6}\\
& \left.\quad+\mathbb{E}\left[\int_{s_{i+l_{1}}}^{T}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{v}^{q-1, p}\right)\right| d v\right]^{j}\right)
\end{align*}
$$

where $C$ denotes a generic constant depending on $T, j$ and $p$.

Let us now upper bound $\mathbb{E}\left(\int_{s_{r}}^{T}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Z_{u}^{q, p}\right|^{2} d u\right)^{j / 2}$. Using (3.6) and the Clark-Ocone formula gives $\int_{0}^{T} Z_{u}^{q, p} d B_{u}=\mathcal{C}_{p}\left(F^{q-1, p}\right)-\mathbb{E}\left(\mathcal{C}_{p}\left(F^{q-1, p}\right)\right)$. Hence, for $v \in\left[s_{r}, T\right]$, we have $\int_{s_{r}}^{v} Z_{u}^{q, p} d B_{u}=\mathbb{E}_{v}\left(\mathcal{C}_{p}\left(F^{q-1, p}\right)\right)-\mathbb{E}_{S_{r}}\left(\mathcal{C}_{p}\left(F^{q-1, p}\right)\right)=$ $Y_{v}^{q, p}+\int_{s_{r}}^{v} f\left(\theta_{u}^{q-1, p}\right) d u-Y_{s_{r}}^{q, p}$. Then, we get

$$
\begin{aligned}
\int_{s_{r}}^{v} D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Z_{u}^{q, p} d B_{u}= & D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{v}^{q, p}-D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{s_{r}}^{q, p} \\
& +\int_{s_{r}}^{v} D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{u}^{q-1, p}\right) d u .
\end{aligned}
$$

The left-hand side of the Burkhölder-Davis-Gundy inequality gives

$$
\begin{aligned}
& \mathbb{E}\left(\int_{s_{r}}^{T}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Z_{u}^{q, p}\right|^{2} d u\right)^{j / 2} \\
& \quad \leq C^{\prime}\left(\mathbb{E}\left[\sup _{u \in\left[s_{r}, T\right]}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} Y_{u}^{q, p}\right|^{j}\right]\right. \\
& \\
& \left.\quad+\mathbb{E}\left[\int_{s_{r}}^{T}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{u}^{q-1, p}\right)\right| d u\right]^{j}\right),
\end{aligned}
$$

where $C^{\prime}$ denotes a generic constant depending on $T$ and $j$. Adding $\left(C^{\prime}+1\right) \times$ (A.6) to the previous equation leads to

$$
\begin{align*}
& \left(D_{t}^{\left(l_{0}\right)} \Delta_{i}^{q, p} D_{s}^{\left(l_{1}\right)}\right)_{j} \\
& \leq C  \tag{A.7}\\
& \quad C\left(\mathbb{E}\left[\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} \xi\right|^{j}\right]\right. \\
& \left.\quad+\mathbb{E}\left[\int_{s_{i+l_{1}}}^{T}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{u}^{q-1, p}\right)\right| d u\right]^{j}\right)
\end{align*}
$$

We introduce two vectors $j$ and $m$, and four integers $k_{0}, k_{1}, l_{0}^{\prime}$ and $l_{1}^{\prime}$ such that $l_{0}^{\prime} \leq l_{0}, l_{1}^{\prime} \leq l_{1},|j|_{1}+|m|_{1}=l-1-l_{0}^{\prime}-l_{1}^{\prime}$ and $k_{0}+k_{1} \leq l . D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{u}^{q-1, p}\right)$ contains a sum of terms of type

$$
\partial_{y}^{k_{0}} \partial_{z}^{k_{1}} f\left(\theta_{u}^{q-1, p}\right) \prod_{i=1}^{k_{0}-1} D_{t s}^{j_{i}} Y_{u}^{q-1, p} \prod_{i=1}^{k_{1}} D_{t s}^{m_{i}} Z_{u}^{q-1, p}\left(D_{t}^{\left(l_{0}^{\prime}\right)} \Delta_{i} D_{s}^{\left(l_{1}^{\prime}\right)} Y_{u}^{q-1, p}\right),
$$

where $a(j)=k_{0}-1$ and $a(m)=k_{1}$ and of type

$$
\partial_{y}^{k_{0}} \partial_{z}^{k_{1}} f\left(\theta_{u}^{q-1, p}\right) \prod_{i=1}^{k_{0}} D_{t s}^{j_{i}} Y_{u}^{q-1, p} \prod_{i=1}^{k_{1}-1} D_{t s}^{m_{i}} Z_{u}^{q-1, p}\left(D_{t}^{\left(l_{0}^{\prime}\right)} \Delta_{i} D_{s}^{\left(l_{1}^{\prime}\right)} Z_{u}^{q-1, p}\right)
$$

where $a(j)=k_{0}, a(m)=k_{1}-1$.

By using Cauchy-Schwarz inequality, we get that $\mathbb{E}\left[\int_{s_{i+l_{1}}}^{T} \mid D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} \times\right.$ $\left.f\left(\theta_{u}^{q-1, p}\right) \mid d u\right]^{j}$ is bounded by

$$
\begin{aligned}
\left\|\partial_{\mathrm{sp}}^{k_{0}+k_{1}} f\right\|_{\infty}^{j} \mathbb{E}\left(\left(\int_{s_{i+l_{1}}}^{T} \prod_{i=1}^{k_{0}-1}\right.\right. & \left.\left(D_{t s}^{j_{i}} Y_{u}^{q-1, p}\right)^{2} \prod_{i=1}^{k_{1}}\left(D_{t s}^{m_{i}} Z_{u}^{q-1, p}\right)^{2} d u\right)^{j / 2} \\
& \left.\times\left(\int_{s_{l_{1}+i}}^{T}\left(D_{t}^{\left(l_{0}^{\prime}\right)} \Delta_{i} D_{s}^{\left(l_{1}^{\prime}\right)} Y_{u}^{q-1, p}\right)^{2} d u\right)^{j / 2}\right)
\end{aligned}
$$

(and the same type of term in $D_{t}^{l_{0}^{\prime}} \Delta_{i} D_{s}^{\left(l_{1}^{\prime}\right)} Z_{u}^{q-1, p}$ ) which leads to

$$
\begin{aligned}
& \mathbb{E}\left[\int_{s_{i+l_{1}}^{T}}^{T}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{u}^{q-1, p}\right)\right| d u\right]^{j} \\
& \quad \leq C\left(\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{k \leq l},\left\|\left(Y^{q-1, p}, Z^{q-1, p}\right)\right\|_{l-1,(l-1) j}\right) \\
& \quad \times \sum_{l_{0}^{\prime}=0}^{l_{0}} \sum_{l_{1}^{\prime}=0}^{l_{1}} \sqrt{\left(D_{t}^{\left(l_{0}^{\prime}\right)} \Delta_{i}^{q-1, p} D_{s}^{\left(l_{1}^{\prime}\right)}\right)_{2 j}}
\end{aligned}
$$

It remains to plug this result into (A.7), to take the supremum in $t_{1}, \ldots, t_{l_{0}}, s_{i+1}$, $\ldots, s_{i+l_{1}}$ and to apply the induction hypothesis to obtain
(A.8) $\sup _{t_{1} \leq \cdots \leq t_{0}} \sup _{s_{i+1} \leq \cdots \leq s_{i+l_{1}}} \mathbb{E}\left[\left(D_{t}^{\left(l_{0}\right)} \Delta_{i}^{q, p} D_{s}^{\left(l_{1}\right)}\right)_{j}\right]$

$$
\begin{align*}
\leq & k_{l}^{\xi}\left(t_{i}-s_{i}\right)^{j \beta_{\xi}}+C\left(\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{1 \leq k \leq l},\left\|\left(Y^{q-1, p}, Z^{q-1, p}\right)\right\|_{l-1,(l-1) j}\right)  \tag{A.9}\\
& \times k_{l}^{q-1, p}\left(t_{i}-s_{i}\right)^{j\left(1 / 2 \wedge \beta_{\xi}\right)}
\end{align*}
$$

and the result follows. If $l_{1}=0$, we get

$$
\begin{aligned}
D_{t}^{\left(l_{0}\right)} \Delta_{i} Y_{u}^{q, p}= & \mathbb{E}_{r}\left[\mathcal{C}_{p-r}\left(D_{t}^{\left(l_{0}\right)} \Delta_{i} F^{q-1, p}\right)\right] \\
& -\int_{s_{i}}^{u} D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{v}^{q-1}\right) d v+\int_{s_{i}}^{t_{i}} D_{t}^{\left(l_{0}\right)} \Delta_{i} D_{s}^{\left(l_{1}\right)} f\left(\theta_{v}^{q-1}\right) d v
\end{aligned}
$$

When bounding $\mathbb{E}\left[\sup _{u \in\left[s_{r}, T\right]}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} Y_{u}^{q, p}\right|^{j}\right]$, we deal with the first two terms as we did before, we bound the term $\mathbb{E}\left[\int_{s_{i}}^{t_{i}}\left|D_{t}^{\left(l_{0}\right)} \Delta_{i} f\left(\theta_{v}^{q-1, p}\right)\right| d v\right]^{j}$ by

$$
C\left(\left(\left\|\partial_{\mathrm{sp}}^{k} f\right\|_{\infty}\right)_{1 \leq k \leq l},\left\|\left(Y^{q-1, p}, Z^{q-1, p}\right)\right\|_{l, l j}\right)\left(t_{i}-s_{i}\right)^{j}
$$

which completes the proof.
A.4. Proof of Lemma 4.14. We prove the result by induction. Lemma 4.14 is true for $p=0$, since $\mathcal{C}_{0}^{N}(F)=\mathcal{C}_{0}(F)$. Assume that $\mathbb{E}\left(\left|\left(\mathcal{C}_{p-1}^{N}-\mathcal{C}_{p-1}\right)(F)\right|^{2}\right) \leq$ $\left(K_{p-1}^{F}\right)^{2}\left(\frac{T}{N}\right)^{2 \alpha_{F}} \sum_{i=1}^{p-1} i^{2} \frac{T_{i}^{i}}{i!}$. Since we have

$$
\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}\right)(F)=\left(\mathcal{C}_{p-1}^{N}-\mathcal{C}_{p-1}\right)(F)+\left(P_{p}^{N}-P_{p}\right)(F)
$$

it remains to show that $\mathbb{E}\left(\left|\left(P_{p}^{N}-P_{p}\right)(F)\right|^{2}\right) \leq\left(k_{p}^{F}\right)^{2}\left(\frac{T}{N}\right)^{2 \alpha_{F}} p^{2} \frac{T^{p}}{p!}$. We recall

$$
\begin{equation*}
P_{p}(F)=\int_{0}^{T} \int_{0}^{s_{p}} \cdots \int_{0}^{s_{2}} u_{p}\left(s_{p}, \ldots, s_{1}\right) d B_{s_{1}} \cdots d B_{s_{p}} \tag{A.10}
\end{equation*}
$$

where $u_{p}: s_{p}, \ldots, s_{1} \longmapsto \mathbb{E}\left(D_{s_{1} \cdots s_{p}}^{(p)} F\right)$,

$$
\begin{equation*}
P_{p}^{N}(F)=\sum_{|n|=p} d_{p}^{n} \prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}\right) \tag{A.11}
\end{equation*}
$$

where $d_{p}^{n}=n!\mathbb{E}\left(F \prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}\right)\right)$. Let us rewrite $P_{p}^{N}(F)$ as a sum of stochastic integrals. Let $r \in \mathbb{N}$. Applying Lemma 2.5 to $g: t \longmapsto \mathbf{1}_{\left.] \bar{t}_{i-1}, \bar{t}_{i}\right]}(t)$ yields $M_{t}^{r}:=h^{r / 2} K_{r}\left(\frac{B_{t}-B_{\bar{t}_{i-1}}}{\sqrt{h}}\right)$ is a martingale and $M_{t}^{r}=\int_{\bar{t}_{i-1}}^{t} M_{s}^{r-1} d B_{s}$. Then, $M_{t}^{r}=$ $\int_{\bar{t}_{i-1}}^{t} \int_{\bar{t}_{i-1}}^{s_{r}} \cdots \int_{\bar{t}_{i-1}}^{s_{2}} M_{s_{1}}^{0} d B_{s_{1}} \cdots d B_{s_{r}}$. For $r=n_{i}$ and $t=\bar{t}_{i}$, we get

$$
K_{n_{i}}\left(G_{i}\right)=\frac{1}{h^{n_{i} / 2}} \int_{\bar{t}_{i-1}}^{\bar{t}_{i}} \int_{\bar{t}_{i-1}}^{s_{n_{i}}} \cdots \int_{\bar{t}_{i-1}}^{s_{2}} d B_{s_{1}} \cdots d B_{s_{n_{i}}}
$$

For $|n|:=n_{1}+\cdots+n_{N}=p$, we obtain

$$
\prod_{1 \leq i \leq N} K_{n_{i}}\left(G_{i}\right)=\frac{1}{h^{p / 2}} \underbrace{\int_{\bar{t}_{N-1}}^{T} \cdots \int_{\bar{t}_{N-1}}^{s_{n(N-1) \mid+2}}}_{n_{N} \text { integrals }} \cdots
$$

(A.13)

$$
\begin{gather*}
\underbrace{\int_{\bar{t}_{1}}^{\bar{t}_{2}} \cdots \int_{\bar{t}_{1}}^{s_{|n(1)|+2}}}_{n_{2} \text { integrals }} \underbrace{\int_{0}^{\bar{t}_{1}} \cdots \int_{0}^{s_{2}}}_{n_{1} \text { integrals }} d B_{s_{1}} \cdots d B_{s_{p}},  \tag{A.12}\\
d_{p}^{n}=n!\frac{1}{h^{p / 2}} \underbrace{\int_{\bar{t}_{N-1}}^{T} \cdots \int_{\bar{t}_{N-1}}^{l_{n n(N-1) \mid+2}} \cdots}_{n_{N} \text { integrals }} \cdots \\
\underbrace{\int_{\bar{t}_{1}}^{\bar{t}_{2}} \cdots \int_{\bar{t}_{1}}^{l_{\ln (1)++2}}}_{n_{2} \text { integrals }} \underbrace{\int_{0}^{\bar{t}_{1}} \cdots \int_{0}^{l_{2}}}_{n_{1} \text { integrals }} u_{p}\left(l_{p}, \ldots, l_{1}\right) d l_{1} \cdots d l_{p} .
\end{gather*}
$$

To compare $P_{p}(F)$ and $P_{p}^{N}(F)$, we split the integrals in (A.10),
(A.14)

$$
P_{p}(F)=\sum_{|n|=p} \underbrace{\int_{\bar{t}_{N-1}}^{T} \cdots \int_{\bar{t}_{N-1}}^{s_{|n(N-1)|+2}} \cdots .}_{n_{N} \text { integrals }} \cdots
$$

Combining (A.11), (A.12), (A.13) and (A.14) yields $\mathbb{E}\left(\left|\left(P_{p}^{N}-P_{p}\right)(F)\right|^{2}\right)=$

$$
\begin{equation*}
\sum_{|n|=p} \underbrace{\int_{\bar{t}_{N-1}}^{T} \cdots \int_{\bar{t}_{N-1}}^{s_{|n(N-1)|+2}} \cdots .}_{n_{N} \text { integrals }} \tag{A.15}
\end{equation*}
$$

Moreover, $\frac{d_{p}^{n}}{h^{p / 2}}-u_{p}\left(s_{p}, \ldots, s_{1}\right)=$

$$
\begin{aligned}
\frac{n!}{h^{p}} & \underbrace{\int_{\bar{t}_{N-1}}^{T} \cdots \int_{\bar{t}_{N-1}}^{l_{N-1}+1}}_{n_{N} \text { integrals }} \cdots \\
& \underbrace{\int_{\bar{t}_{1}}^{\bar{t}_{2}} \cdots \int_{\bar{t}_{1}}^{l_{n_{1}}+1}}_{n_{2} \text { integrals }} \underbrace{\int_{0}^{\bar{t}_{1}} \cdots \int_{0}^{l_{2}}}_{n_{1} \text { integrals }}\left(u_{p}\left(l_{p}, \ldots, l_{1}\right)-u_{p}\left(s_{p}, \ldots, s_{1}\right)\right) d l_{1} \cdots d l_{p}
\end{aligned}
$$

Since $u_{p}$ satisfies Hypothesis 4.1, we get $\left|u_{p}\left(l_{p}, \ldots, l_{1}\right)-u_{p}\left(s_{p}, \ldots, s_{1}\right)\right| \leq$ $k_{p}^{F}\left(\left|l_{p}-s_{p}\right|^{\beta_{F}}+\cdots+\left|l_{1}-s_{1}\right|^{\beta_{F}}\right) \leq p k_{p}^{F} h^{\beta_{F}}$. Then $\left|\frac{d_{p}^{n}}{h^{p / 2}}-u_{p}\left(s_{p}, \ldots, s_{1}\right)\right| \leq$ $p k_{p}^{F} h^{\beta_{F}}$. Plugging this result into (A.15) completes the proof.
A.5. Proof of Lemma 4.16. Using definitions (2.8) and (3.10) leads to

$$
\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}^{N, M}\right)(F)=d_{0}-\hat{d}_{0}+\sum_{k=1}^{p} \sum_{|n|=k}\left(d_{k}^{n}-\hat{d}_{k}^{n}\right) \prod_{i=1}^{N} K_{n_{i}}\left(G_{i}\right)
$$

Since $\hat{d_{k}^{n}}$ is independent of $\left(G_{i}\right)_{i}$,

$$
\mathbb{E}\left(\left|\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}^{N, M}\right)(F)\right|^{2}\right)=\mathbb{E}\left(\left|d_{0}-\hat{d}_{0}\right|^{2}\right)+\sum_{k=1}^{p} \sum_{|n|=k} \frac{1}{n!} \mathbb{E}\left(\left|d_{k}^{n}-\hat{d}_{k}^{n}\right|^{2}\right)
$$

The definition of the coefficients $d_{0}$ and $d_{k}^{n}$ given in (2.9) leads to

$$
\mathbb{E}\left(\left|\left(\mathcal{C}_{p}^{N}-\mathcal{C}_{p}^{N, M}\right)(F)\right|^{2}\right)=\mathbb{V}\left(\hat{d}_{0}\right)+\sum_{k=1}^{p} \sum_{|n|=k} \frac{1}{n!} \mathbb{V}\left(\hat{d}_{k}^{n}\right)
$$

and the first result follows. To get the second result, we write $\mathcal{C}_{p}^{N, M}(F)=\left(\mathcal{C}_{p}^{N, M}-\right.$ $\left.\mathcal{C}_{p}^{N}\right)(F)+\mathcal{C}_{p}^{N}(F)$. Since $\mathbb{E}\left(\left(\mathcal{C}_{p}^{N, M}-\mathcal{C}_{p}^{N}\right)(F) \mathcal{C}_{p}^{N}(F)\right)=0$, we get

$$
\mathbb{E}\left(\left|\mathcal{C}_{p}^{N, M}(F)\right|^{2}\right)=\mathbb{E}\left(\left|\left(\mathcal{C}_{p}^{N, M}-\mathcal{C}_{p}^{N}\right)(F)\right|^{2}\right)+\mathbb{E}\left(\left|\mathcal{C}_{p}^{N}(F)\right|^{2}\right)
$$

Lemma 2.6 completes the proof.

## APPENDIX B: WIENER CHAOS EXPANSION FORMULAS

B.1. Proof of Proposition 2.7. First, we compute $\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N}(F)\right)$ for $t \in$ $\left.] \bar{t}_{r-1}, \bar{t}_{r}\right]$. From (2.8), we get

$$
\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)=d_{0}+\sum_{k=1}^{p} \sum_{|n|=k} d_{k}^{n} \prod_{i<r} K_{n_{i}}\left(G_{i}\right) \times \mathbb{E}_{t}\left(\prod_{i \geq r} K_{n_{i}}\left(G_{i}\right)\right)
$$

Since Brownian increments are independent, we get $\mathbb{E}_{\bar{t}_{r}}\left(\prod_{i \geq r} K_{n_{i}}\left(G_{i}\right)\right)=$ $K_{n_{r}}\left(G_{r}\right) \prod_{i>r} \mathbb{E}\left[K_{n_{i}}\left(G_{i}\right)\right]$, which is null as soon as $n_{r+1}+\cdots+n_{N}>0$. Then, nested conditional expectations give

$$
\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)=d_{0}+\sum_{k=1}^{p} \sum_{|n(r)|=k} d_{k}^{n} \prod_{i<r} K_{n_{i}}\left(G_{i}\right) \times \mathbb{E}_{t}\left(K_{n_{r}}\left(G_{r}\right)\right)
$$

By applying Lemma 2.5 when $g: t \longmapsto \mathbf{1}_{\left[\bar{t}_{r-1}, \bar{t}_{r}\right]}(t)$, we get $\mathbb{E}_{t}\left(K_{n_{r}}\left(G_{r}\right)\right)=$ $\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{n_{r} / 2} K_{n_{r}}\left(\frac{B_{t}-B_{\bar{t}_{r-1}}}{\sqrt{t-\bar{t}_{r-1}}}\right)$, which yields the first result. Since $K_{n}^{\prime}(x)=K_{n-1}(x)$, the second result follows.
B.2. Wiener chaos expansion formulas in $\mathbb{R}^{\boldsymbol{d}}$. We want to approximate $F \in$ $\mathrm{L}^{2}\left(\mathcal{F}_{T}\right)$ using its chaos decomposition up to order $p$. We assume $N \geq d p$. We consider the following truncated basis of $\mathrm{L}^{2}\left([0, T] ; \mathbb{R}^{d}\right)$ :

$$
\frac{\mathbf{1}_{\left.\overline{t_{i-1}, \bar{t}_{i}}\right]}(t)}{\sqrt{h}} e_{j}, \quad i=1, \ldots, N, j=1, \ldots, d, \text { where } h=\frac{T}{N},
$$

where $\left\{\bar{t}_{i}:=i h, i=0, \ldots, N\right\}$ is a regular mesh grid, and $\left(e_{j}\right)_{1 \leq j \leq d}$ represents the canonical basis of $\mathbb{R}^{d}$. $P_{k}$, the $k$ th chaos, is generated by

$$
\left\{\prod_{j=1}^{d} \prod_{i=1}^{N} K_{n_{i}^{j}}\left(G_{i}^{j}\right): \sum_{j=1}^{d} \sum_{i=1}^{N} n_{i}^{j}=k\right\}, \quad G_{i}^{j}=\frac{\Delta_{i}^{j}}{\sqrt{h}}, \Delta_{i}^{j}=B_{\bar{t}_{i}}^{j}-B_{\bar{t}_{i-1}}^{j}
$$

For $j=1, \ldots, d, n^{j}=\left(n_{1}^{j}, \ldots, n_{N}^{j}\right)$, one notes $\left|n^{j}\right|=n_{1}^{j}+\cdots+n_{N}^{j}, n^{j}!=$ $n_{1}^{j}!\cdots n_{N}^{j}!$, and for $r \leq N, n^{j}(r)=\left(n_{1}^{j}, \ldots, n_{r}^{j}\right) . n=\left(n^{1}, \ldots, n^{d}\right)^{*},|n|=$ $\left|n^{1}\right|+\cdots+\left|n^{d}\right|, n!=n^{1}!\cdots n^{d}!$ and $n(r)=\left(n^{1}(r), \ldots, n^{d}(r)\right)^{*}$. Since the r.v. $\left(\prod_{1 \leq j \leq d} \prod_{1 \leq i \leq N} K_{n_{i}^{j}}\left(G_{i}^{j}\right)\right)_{n}$ are orthogonal ones, the projection of $F$ is given by

$$
\mathcal{C}_{p}^{N}(F)=d_{0}+\sum_{k=1}^{p} \sum_{|n|=k} d_{k}^{n} \prod_{1 \leq j \leq d} \prod_{1 \leq i \leq N} K_{n_{i}^{j}}\left(G_{i}^{j}\right),
$$

where the coefficients $d_{k}^{n}$ are given by

$$
d_{k}^{n}=n!\mathbb{E}\left[F \prod_{1 \leq j \leq d} \prod_{1 \leq i \leq N} K_{n_{i}^{j}}\left(G_{i}^{j}\right)\right]
$$

Proposition B.1. For $\bar{t}_{r-1}<t \leq \bar{t}_{r}$, we have

$$
\begin{aligned}
\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)=d_{0}+ & \sum_{k=1}^{p} \sum_{|n(r)|=k} d_{k}^{n} \prod_{i<r} \prod_{1 \leq j \leq d} K_{n_{i}^{j}}\left(G_{i}^{j}\right) \\
& \times \prod_{1 \leq j \leq d}\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{n_{r}^{j} / 2} K_{n_{r}^{j}}\left(\frac{B_{t}^{j}-B_{\bar{t}_{r-1}}^{j}}{\sqrt{t-\bar{t}_{r-1}}}\right),
\end{aligned}
$$

and for $l=1, \ldots, d$,

$$
\begin{aligned}
& D_{t}^{l}\left(\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)\right) \\
& =\sum_{k=1}^{p} \sum_{\substack{|n(r)|=k \\
n_{r}^{l}>0}} d_{k}^{n} h^{-1 / 2} \prod_{i<r} \prod_{1 \leq j \leq d} K_{n_{i}^{j}}\left(G_{i}^{j}\right)\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{\left(n_{r}^{l}-1\right) / 2} \\
& \quad \times K_{n_{r}^{l}-1}\left(\frac{B_{t}^{l}-B_{\bar{t}_{r-1}}^{l}}{\sqrt{t-\bar{t}_{r-1}}}\right) \\
& \quad \times \prod_{j \neq l}\left(\frac{t-\bar{t}_{r-1}}{h}\right)^{n_{r}^{j} / 2} K_{n_{r}^{j}}\left(\frac{B_{t}^{j}-B_{\bar{t}_{r-1}}^{j}}{\sqrt{t-\bar{t}_{r-1}}}\right)
\end{aligned}
$$

REMARK B.2. In particular, for $t=\bar{t}_{r}, r \geq 1$ and $l=1, \ldots, d$,

$$
\begin{aligned}
\mathbb{E}_{\bar{t}_{r}}\left(\mathcal{C}_{p}^{N} F\right) & =d_{0}+\sum_{k=1}^{p} \sum_{|n(r)|=k} d_{k}^{n} \prod_{i \leq r} \prod_{1 \leq j \leq d} K_{n_{i}^{j}}\left(G_{i}^{j}\right), \\
D_{\bar{t}_{r}}^{l}\left(\mathbb{E}_{\bar{t}_{r}}\left(\mathcal{C}_{p}^{N} F\right)\right) & =\sum_{\substack{k=1}}^{p} \sum_{\substack{|n(r)|=k \\
n_{r}^{l}>0}} d_{k}^{n} h^{-1 / 2} \prod_{i<r} \prod_{1 \leq j \leq d} K_{n_{i}^{j}}\left(G_{i}^{j}\right) K_{n_{r}^{l}-1}\left(G_{r}^{l}\right) \prod_{j \neq l} K_{n_{r}^{j}}\left(G_{r}^{j}\right) .
\end{aligned}
$$

When $r=0$, we get $\mathbb{E}_{\bar{t}_{0}}\left(\mathcal{C}_{p}^{N} F\right)=d_{0}$, and we define $D_{\bar{t}_{0}}^{l}\left(\mathbb{E}_{\bar{t}_{0}}\left(\mathcal{C}_{p}^{N} F\right)\right)=\frac{1}{\sqrt{h}} d_{1}^{l_{1}^{l}}$, where $\left(e_{j}^{i}\right)$ is a matrix of size $d \times N$ whose component $(i, j)$ equals 1 and the other ones are null.

Proof of Proposition B.1. We first compute $\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)$ for $\left.\left.t \in\right] \bar{t}_{r-1}, \bar{t}_{r}\right]$. We have

$$
\mathbb{E}_{t}\left(\mathcal{C}_{p}^{N} F\right)=d_{0}+\sum_{k=1}^{p} \sum_{|n|=k} d_{k}^{n} \prod_{i<r} \prod_{1 \leq j \leq d} K_{n_{i}^{j}}\left(G_{i}^{j}\right) \times \mathbb{E}_{t}\left(\prod_{i \geq r} \prod_{1 \leq j \leq d} G_{n_{i}^{j}}\left(W_{i}^{j}\right)\right)
$$

Since Brownian motions and their increments are independents, we get

$$
\mathbb{E}_{\bar{t}_{r}}\left(\prod_{i \geq r} \prod_{1 \leq j \leq d} K_{n_{i}^{j}}\left(G_{i}^{j}\right)\right)=\prod_{1 \leq j \leq d} K_{n_{r}^{j}}\left(G_{r}^{j}\right) \prod_{i>r} \prod_{1 \leq j \leq d} \mathbb{E}\left[K_{n_{i}^{j}}\left(G_{i}^{j}\right)\right]
$$

which is null as soon as $n_{r+1}^{1}+\cdots+n_{N}^{1}+\cdots+n_{r+1}^{d}+\cdots+n_{N}^{d}>0$. Then nested conditional expectations give

$$
\mathbb{E}_{t}(F)=d_{0}+\sum_{k=1}^{p} \sum_{|n(r)|=k} d_{k}^{n} \prod_{i<r} \prod_{1 \leq j \leq d} K_{n_{i}^{j}}\left(G_{i}^{j}\right) \times \mathbb{E}_{t}\left(\prod_{1 \leq j \leq d} K_{n_{r}^{j}}\left(G_{r}^{j}\right)\right)
$$

From Lemma 2.5, for $j=1, \ldots, d M_{t}^{n_{r}^{j}}:=\left(t-\bar{t}_{r-1}\right)^{n_{r}^{j} / 2} K_{n_{r}^{j}}\left(\frac{B_{t}^{j}-B_{\bar{t}_{r-1}}^{j}}{\sqrt{t-\bar{t}_{r-1}}}\right)$ is a martingale and $d M_{t}^{n_{r}^{j}}=M_{t}^{n_{r}^{j}-1} \mathbf{1}_{\left.\bar{t}_{r-1}, \bar{t}_{r}\right]}(t) d B_{t}^{j}$. Then $\prod_{1 \leq j \leq d}\left(t-\bar{t}_{r-1}\right)^{n_{r}^{j} / 2} \times$ $K_{n_{r}^{j}}\left(\frac{B_{t}^{j}-B_{\bar{t}_{r-1}}^{j}}{\sqrt{t-\bar{t}_{r-1}}}\right)$ is also a martingale, and the first result follows. Since $K_{n_{r}^{l}}^{\prime}(x)=$ $K_{n_{r}^{l}-1}(x)$, we get the second result.
