# AN EDGEWORTH EXPANSION FOR SYMMETRIC FINITE POPULATION STATISTICS 

By M. Bloznelis ${ }^{1}$ and F. GöTZE<br>Vilnius University and Bielefeld University

#### Abstract

Let $T$ be a symmetric statistic based on sample of size $n$ drawn without replacement from a finite population of size $N$, where $N>n$. Assuming that the linear part of Hoeffding's decomposition of $T$ is nondegenerate we construct a one term Edgeworth expansion for the distribution function of $T$ and prove the validity of the expansion with the remainder $O\left(1 / n^{*}\right)$ as $n^{*} \rightarrow \infty$, where $n^{*}=\min \{n, N-n\}$.

1. Introduction and results. Given a set $\mathcal{X}=\left\{x_{1}, \ldots, x_{N}\right\}$, let $\left(X_{1}, \ldots, X_{N}\right)$ be a random permutation of the ordered set $\left(x_{1}, \ldots, x_{N}\right)$. We assume that the random permutation is uniformly distributed over the class of permutations. Let

$$
T=t\left(X_{1}, \ldots, X_{n}\right)
$$

denote a symmetric statistic of the first $n$ observations $X_{1}, \ldots, X_{n}$, where $n<N$. That is, $t$ is a real function defined on the class of subsets $\left\{x_{i_{1}}, \ldots, x_{i_{n}}\right\} \subset \mathcal{X}$ of size $n$ and we assume that $t\left(x_{i_{1}}, \ldots, x_{i_{n}}\right)$ is invariant under permutations of its arguments. Since $X_{1}, \ldots, X_{n}$ represents a sample drawn without replacement from the population $X$, we call $T$ a symmetric finite population statistic.

We shall consider symmetric finite population statistics which are asymptotically normal when $n^{*}$ and $N$ tend to $\infty$, where $n^{*}=\min \{n, N-n\}$. In the simplest case of linear statistics the asymptotic normality was established by Erdős and Rényi (1959) under fairly general conditions. The rate in the Erdôs-Rényi central limit theorem was studied by Bikelis (1972). Höglund (1978) proved the BerryEsseen bound. An Edgeworth expansion was established by Robinson (1978), see also Bickel and van Zwet (1978), Schneller (1989), Babu and Bai (1996).

Asymptotic normality of nonlinear finite population statistics was studied by Nandi and Sen (1963), who proved a central limit theorem for $U$-statistics. The accuracy of the normal approximation of $U$-statistics was studied by Zhao and Chen (1987, 1990), Kokic and Weber (1990). A general Berry-Esseen bound for combinatorial multivariate sampling statistics (including finite population $U$-statistics) was established by Bolthausen and Götze (1993). Rao and Zhao

[^0](1994), Bloznelis (1999) constructed Berry-Esseen bounds for Student's $t$ statistic. One term asymptotic expansions of nonlinear statistics, which can be approximated by smooth functions of (multivariate) sample means have been shown by Babu and Singh (1985), see also Babu and Bai (1996). For $U$-statistics of degree two one term Edgeworth expansions were constructed by Kokic and Weber (1990). Bloznelis and Götze $(1999,2000)$ established the validity of one term Edgeworth expansion for $U$-statistics of degree two with remainders $o\left(1 / \sqrt{n^{*}}\right)$ and $O\left(1 / n^{*}\right)$.

A second order asymptotic theory for general asymptotically normal symmetric statistics of independent and identically distributed observations was developed in a recent paper by Bentkus, Götze and van Zwet (1997), which concludes a number of previous investigations of particular statistics: Bickel (1974), Callaert and Janssen (1978), Götze (1979), Callaert, Janssen and Veraverbeke (1980), Serfling (1980), Helmers (1982), Helmers and van Zwet (1982), van Zwet (1984), Bickel, Götze and van Zwet (1986), Lai and Wang (1993), etc. This theory is based on the representation of symmetric statistics by sums of $U$-statistics of increasing order via Hoeffding's decomposition. Another approach [see, for example, Chibisov (1972), Pfanzagl (1973), Bhattacharya and Ghosh (1978)], which is based on Taylor expansions of statistics in powers of the underlying i.i.d. observations, focuses on smooth functions of observations.

In view of important classes of applications [jackknife histogram, see Wu (1990), Shao (1989), Booth and Hall (1993), and subsampling, see Politis and Romano (1994), Bertail (1997), Bickel, Götze and van Zwet (1997)] in this paper we want to develop a second order asymptotic theory similar to that of Bentkus, Götze and van Zwet (1997) for simple random samples drawn without replacement from finite populations.

The starting point of our asymptotic analysis is the Hoeffding decomposition

$$
\begin{equation*}
T=\mathbf{E} T+\sum_{1 \leq i \leq n} g_{1}\left(X_{i}\right)+\sum_{1 \leq i<j \leq n} g_{2}\left(X_{i}, X_{j}\right)+\cdots \tag{1.1}
\end{equation*}
$$

which expands $T$ into the sum of mutually uncorrelated $U$-statistics of increasing order

$$
\begin{equation*}
U_{k}=\sum_{1 \leq i_{1}<\cdots<i_{k} \leq n} g_{k}\left(X_{i_{1}}, \ldots, X_{i_{k}}\right), \quad k=1, \ldots, n . \tag{1.2}
\end{equation*}
$$

Here the symmetric kernels $g_{k}, k=1, \ldots, n$, are centered, $\mathbf{E} g_{k}\left(X_{1}, \ldots, X_{k}\right)=0$, and satisfy the orthogonality condition

$$
\begin{equation*}
\mathbf{E}\left(g_{k}\left(X_{1}, \ldots, X_{k}\right) \mid X_{1}, \ldots, X_{k-1}\right)=0 \quad \text { almost surely } . \tag{1.3}
\end{equation*}
$$

It follows from (1.3) that $U_{1}, \ldots, U_{n}$ are orthogonal in $L_{2}$ (i.e., $\mathbf{E} U_{k} U_{r}=0$, for $k \neq r$ ). Furthermore, condition (1.3) ensures the uniqueness of decomposition (1.1) in the following sense: given another decomposition like (1.1) with symmetric kernels, say $g_{k}^{\prime}$, satisfying (1.3), we always have $g_{k}=g_{k}^{\prime}$.

Let us mention briefly that given $k$, the function $g_{k}\left(x_{i_{1}}, \ldots, x_{i_{k}}\right)$ can be expressed by a linear combination of conditional expectations $\mathbf{E}\left(T-\mathbf{E} T \mid X_{1}=\right.$ $x_{r_{1}}, \ldots, X_{j}=x_{r_{j}}$ ) where $j=1, \ldots, k$ and $\left\{x_{r_{1}}, \ldots, x_{r_{j}}\right\} \subset\left\{x_{i_{1}}, \ldots, x_{i_{k}}\right\}$. The expressions for $g_{1}$ and $g_{2}$ are provided by (1.5) below. For larger $k=3, \ldots, n$, the expressions are more complex and we refer to Bloznelis and Götze (2001) where a general formula for $g_{k}$ is derived.

We shall assume that the linear part $U_{1}=\sum g_{1}\left(X_{i}\right)$ is nondegenerate. That is, $\sigma^{2}>0$, where $\sigma^{2}=\operatorname{Var} g_{1}\left(X_{1}\right)$. In the case where, for large $n^{*}$, the linear part dominates the statistic we can approximate the distribution of $T$ by a normal distribution, using the central limit theorem. Furthermore, the sum of the linear and quadratic term,

$$
U=\mathbf{E} T+\sum_{1 \leq i \leq n} g_{1}\left(X_{i}\right)+\sum_{1 \leq i<j \leq n} g_{2}\left(X_{i}, X_{j}\right)
$$

typically provides a sufficiently precise approximation to $T$ so that one term Edgeworth expansions for the distribution functions of $T$ and $U$ are, in fact, the same. Therefore, in order to construct a one term Edgeworth expansion of $T$ it suffices to find such expansion for $U$. In particular, we do not need to evaluate all the summands of the decomposition (1.1), but (moments of) the first two terms only, cf. (1.4) below. Similarly, the two term Edgeworth expansion for the distribution function of $T$ could be constructed using the approximation $T \approx \mathbf{E} T+U_{1}+U_{2}+U_{3}$, etc. An advantage of such an approach is that it provides (at least formal) Edgeworth expansion for an arbitrary symmetric finite population statistic $T$ no matter whether it is a smooth function of observations or not. In the present paper we construct the one term Edgeworth expansion for the distribution function of $T$ and prove the validity of the expansion with the remainder $O\left(1 / n^{*}\right)$.

A simple calculation shows that the variance of the linear part satisfies

$$
\operatorname{Var} \sum_{1 \leq i \leq n} g_{1}\left(X_{i}\right)=\sigma^{2} \tau^{2} \frac{N}{N-1}, \quad \tau^{2}=N p q, \quad p=n / N, \quad q=1-p .
$$

Note that $n^{*} / 2 \leq \tau^{2} \leq n^{*}$. We approximate the distribution function

$$
F(x)=\mathbf{P}\{T \leq \mathbf{E} T+\sigma \tau x\},
$$

by the one term Edgeworth expansion

$$
\begin{equation*}
G(x)=\Phi(x)-\frac{(q-p) \alpha+3 \kappa}{6 \tau} \Phi^{(3)}(x) \tag{1.4}
\end{equation*}
$$

and provide an explicit bound for the remainder

$$
\Delta=\sup _{x \in R}|F(x)-G(x)|,
$$

where

$$
\alpha=\sigma^{-3} \mathbf{E} g_{1}^{3}\left(X_{1}\right) \quad \text { and } \quad \kappa=\sigma^{-3} \tau^{2} \mathbf{E} g_{2}\left(X_{1}, X_{2}\right) g_{1}\left(X_{1}\right) g_{1}\left(X_{2}\right)
$$

and where

$$
\begin{align*}
g_{1}\left(X_{i}\right)= & \frac{N-1}{N-n} \mathbf{E}\left(T^{\prime} \mid X_{i}\right), \quad T^{\prime}=T-\mathbf{E} T, \\
g_{2}\left(X_{i}, X_{j}\right)= & \frac{N-2}{N-n} \frac{N-3}{N-n-1}  \tag{1.5}\\
& \times\left(\mathbf{E}\left(T^{\prime} \mid X_{i}, X_{j}\right)-\frac{N-1}{N-2}\left(\mathbf{E}\left(T^{\prime} \mid X_{i}\right)+\mathbf{E}\left(T^{\prime} \mid X_{j}\right)\right)\right) .
\end{align*}
$$

Furthermore, $\Phi$ denotes the standard normal distribution function, and $\Phi^{(3)}$ denotes the third derivative of $\Phi$.

Before formulating our main results, Theorems 1.1 and 1.2 , we introduce the smoothness conditions, which together with the moment conditions, ensure the validity of the expansion (1.4).
1.2. Smoothness conditions. Given a general symmetric statistic $T$ we approximate it by a $U$-statistic via Hoeffding's decomposition. In order to control the accuracy of such an approximation we use moments of finite differences of $T$. Introduce the difference operation

$$
D^{j} T=t\left(X_{1}, \ldots, X_{j}, \ldots, X_{n}\right)-t\left(X_{1}, \ldots, X_{j}^{\prime}, \ldots, X_{n}\right), \quad X_{j}^{\prime}=X_{n+j},
$$

where $X_{j}$ is replaced by $X_{j}^{\prime}$ in the second summand, for $j \leq n^{*}$. Higher order difference operations are defined recursively:

$$
D^{j_{1}, j_{2}} T=D^{j_{2}}\left(D^{j_{1}} T\right), \quad D^{j_{1}, j_{2}, j_{3}} T=D^{j_{3}}\left(D^{j_{2}}\left(D^{j_{1}} T\right)\right), \ldots
$$

It is easy to see that the difference operations are symmetric, that is, $D^{j_{1}, j_{2}} T=$ $D^{j_{2}, j_{1}} T$, etc. Given $k<n^{*}$ write

$$
\delta_{j}=\delta_{j}(T)=\mathbf{E}\left(\tau^{2(j-1)} \mathbb{D}_{j} T\right)^{2}, \quad \mathbb{D}_{j} T=D^{1,2, \ldots, j} T, 1 \leq j \leq k .
$$

Bounds for the accuracy of the approximation of $T$ by the sum of the first few terms of the decomposition (1.1) are provided by the following theorem.

Theorem A [Bloznelis and Götze (2001)]. For $1 \leq k<n^{*}$, we have

$$
\begin{equation*}
T=\mathbf{E} T+U_{1}+\cdots+U_{k}+R_{k} \quad \text { with } \mathbf{E} R_{k}^{2} \leq \tau^{-2(k-1)} \delta_{k+1} \tag{1.6}
\end{equation*}
$$

In typical situations ( $U$-statistics, smooth functions of sample means, Student's $t$ and many others) for a properly standardized statistic $T$ we have $U_{j}=$ $O_{P}\left(\tau^{1-j}\right)$, for $j=1, \ldots, k$, and

$$
\begin{equation*}
\delta_{k+1}=O\left(\tau^{-2}\right) \quad \text { as } n^{*}, N \rightarrow \infty \tag{1.7}
\end{equation*}
$$

for some $k$. Note that (1.7) can be viewed as a smoothness condition. For instance, given a statistic which is a function of the sample mean this condition is satisfied
in the case where the function (defining the statistic) is $k+1$ times differentiable; see Bloznelis and Götze (2001).

Assuming that (1.7) holds for $k=2$ we obtain from Theorem A that $T=$ $U+O_{P}\left(\tau^{-2}\right)$ thus, showing that up to an error $O\left(\tau^{-2}\right)$ the statistics $T$ and $U$ are asymptotically equivalent. Finally, we remark that (1.7) holds if $\delta_{k+1} / \sigma^{2}$ and the variance of the linear part $\operatorname{Var} U_{1}$ remain bounded as $n^{*}, N \rightarrow \infty$.

Another smoothness condition we are going to use is a Cramér type condition. Recall Cramér's (C) condition for the distribution $F_{Z}$ of a random variable $Z$,

$$
\begin{equation*}
\sup _{|t|>\delta}|\mathbf{E} \exp \{i t Z\}|<1 \quad \text { for some } \delta>0 \tag{C}
\end{equation*}
$$

In the classical theory of sums of independent random variables, this condition, together with moment conditions, ensures the validity of Edgeworth expansions with remainders $O\left(n^{-k / 2}\right)$ and $o\left(n^{-k / 2}\right), k=2,3, \ldots$, for the distribution function of the sum of $n$ independent observations from the distribution $F_{Z}$; see Petrov (1975).

In our situation a condition like (C) is too stringent. We shall use a modification of (C) which is applicable to random variables assuming a finite number of values only. For the summand of the linear part $Z=\sigma^{-1} g_{1}\left(X_{1}\right)$, we assume that $\rho>0$, where

$$
\rho:=1-\sup \left\{|\mathbf{E} \exp \{i t Z\}|: b_{1} / \beta_{3} \leq|t| \leq \tau\right\} .
$$

Here $b_{1}$ is a small absolute constant (one may choose, e.g., $b_{1}=0.001$ ) and $\beta_{3}=\sigma^{-3} \mathbf{E}\left|g_{1}\left(X_{1}\right)\right|^{3}$. Other modifications of Cramér's (C) condition which are applicable to discrete random variables were considered by Albers, Bickel and van Zwet (1976), Robinson (1978) and Bloznelis and Götze (2000), where in the latter paper relations between various conditions are discussed.
1.3. Results. Write $\zeta=\sigma^{-2} \tau^{8} \mathbf{E} g_{3}^{2}\left(X_{1}, X_{2}, X_{3}\right)$ and denote

$$
\beta_{k}=\sigma^{-k} \mathbf{E}\left|g_{1}\left(X_{1}\right)\right|^{k}, \quad \gamma_{k}=\sigma^{-k} \tau^{2 k} \mathbf{E}\left|g_{2}\left(X_{1}, X_{2}\right)\right|^{k}, k=2,3,4 .
$$

THEOREM 1.1. There exists an absolute constant $c>0$ such that

$$
\begin{equation*}
\Delta \leq \frac{c}{\tau^{2}} \frac{\beta_{4}+\gamma_{4}+\zeta}{\rho^{2}}+\frac{c}{\tau^{2}} \frac{\delta_{4}}{\sigma^{2} \rho^{2}} . \tag{1.8}
\end{equation*}
$$

For $U$-statistics of arbitrary but fixed degree $k$,

$$
\begin{equation*}
\sum_{1 \leq i_{1}<\cdots<i_{k} \leq n} h\left(X_{i_{1}}, \ldots, X_{i_{k}}\right), \tag{1.9}
\end{equation*}
$$

where $h$ is a real symmetric function defined on $k$-subsets of $\mathcal{X}$, we have the following bound.

ThEOREM 1.2. There exist an absolute constant $c>0$ and a constant $c(k)>0$ depending only on $k$ such that

$$
\begin{equation*}
\Delta \leq \frac{c}{\tau^{2}} \frac{\beta_{4}+\gamma_{4}}{\rho^{2}}+\frac{c(k)}{\tau^{2}} \frac{\delta_{3}}{\sigma^{2} \rho^{2}} . \tag{1.10}
\end{equation*}
$$

Since the absolute constants are not specified, Theorems 1.1 and 1.2 should be viewed as asymptotic results. Assume that the population size $N \rightarrow \infty$ and the sample size $n$ increases so that $n^{*} \rightarrow \infty$. In particular, $\tau \rightarrow \infty$. In those models where $\beta_{4}, \gamma_{4}$ and $\zeta+\delta_{4} / \sigma^{2}$ (respectively $\delta_{3} / \sigma^{2}$ ) remain bounded and

$$
\begin{equation*}
\liminf \rho>0 \tag{1.11}
\end{equation*}
$$

Theorem 1.1 (respectively Theorem 1.2) provides the bound $\Delta=O\left(\tau^{-2}\right)$. Since $n^{*} / 2 \leq \tau^{2} \leq n^{*}$ we obtain $\Delta=O\left(1 / n^{*}\right)$.

Remark 1. Note that the bounds of Theorems 1.1 and 1.2 are established without any additional assumption on $p$ and $q$. This fact is important for applications, like subsampling, where $p$ or $q$ may tend to zero as $N \rightarrow \infty$.

REMARK 2. The bound of order $O\left(\tau^{-2}\right)$ for the remainder is unimprovable, because the next term of the Edgeworth expansion, at least for linear statistics, is of order $O\left(\tau^{-2}\right)$; see Robinson (1978).

REmARK 3. An expansion of the probability $P\{T \leq \mathbf{E} T+\sigma \tau x\}$ in powers of $\tau^{-1}$ would be the most natural choice of asymptotics. We invoke two simple arguments supporting this choice. First, $\tau^{2}$ is proportional to the variance of the linear part. Second, the number of observations $n$ does not longer determine the scale of $T$ in the case where samples are drawn without replacement since the statistic effectively depends on $n^{*}\left(\approx \tau^{2}\right)$ observations. Indeed, it was shown in Bloznelis and Götze (2001) that, for $n>N-n$, we have almost surely

$$
\begin{equation*}
T=T^{*}, \quad T^{*}=\mathbf{E} T+U_{1}^{*}+\cdots+U_{n^{*}}^{*}, \tag{1.12}
\end{equation*}
$$

where we denote

$$
U_{k}^{*}=\sum_{1 \leq i_{1}<\cdots<i_{k} \leq n^{*}}(-1)^{k} g_{k}\left(X_{i_{1}}^{\prime}, \ldots, X_{i_{k}}^{\prime}\right), \quad X_{j}^{\prime}=X_{n+j}
$$

That is, $T$ effectively depends on $n^{*}=N-n$ observations $X_{1}^{\prime}, \ldots, X_{n^{*}}^{\prime}$ only.
REmARK 4. The bounds of Theorems 1.1 and 1.2 are optimal in the sense that it is impossible to approximate $F$ by a continuous differentiable function, like $G$, with the remainder $o\left(\tau^{-2}\right)$, if no additional smoothness condition apart from (1.11)
is imposed. Already for $U$-statistics of degree two, Cramér's condition (1.11), together with moment conditions of arbitrary order, do not suffice to establish the approximation of order $o\left(\tau^{-2}\right)$. This fact is demonstrated by means of a counter example in Bentkus, Götze and van Zwet (1997) in the i.i.d. situation, and it is inherited by finite population statistics. Indeed, in the case where $N \rightarrow \infty$ and $n$ remains fixed the simple random sample model approaches the i.i.d. situation. We have $\tau \rightarrow \sqrt{n}, p \rightarrow 0, q \rightarrow 1$. Replacing $\tau, p$ and $q$ by $\sqrt{n}, 0$ and 1 respectively we obtain from $G$ the one term Edgeworth expansion for the distribution function of symmetric statistic based on i.i.d. observations, which was constructed in Bentkus, Götze and van Zwet (1997).

REMARK 5. The bound (1.8) involves moments (of nonlinear parts) which are higher than those which are necessary to define expansions. Thus, in an optimal dependence on moments one would like to replace $\gamma_{4}+\zeta+\delta_{4} / \sigma^{2}$ by $\gamma_{2}+\delta_{3} / \sigma^{2}$ in the remainder. Let us mention also that for $U$-statistics of degree $k$, where $k$ is fixed, the bound (1.10) is more precise than (1.8). Indeed, a straightforward calculation shows that for some absolute constant $c$ we have $\delta_{3} \leq c \sigma^{2} \zeta+c \delta_{4} \tau^{-2}$. Our technique allows us to prove (1.10) for the $U$-statistics only and with $c(k) \rightarrow \infty$, for $k \rightarrow \infty$.

In order to apply our results to particular classes of statistics one has to estimate moments $\delta_{3}$ or $\delta_{4}$ of differences $\mathbb{D}_{3} T$ or $\mathbb{D}_{4} T$. For $U$-statistics and smooth functions of sample means this problem is easy and routine, see Bloznelis and Götze (2001). Some applications of our results to resampling procedures are considered ibidem.

The remaining part of the paper is organized as follows. In Section 2 we prove Theorem 1.2. Theorem 1.1 is a consequence of Theorem 1.2. In the proof we use the "data dependent smoothing technique," first introduced in Bentkus, Götze and van Zwet (1997), and expansions of characteristic functions. Expansions of characteristic functions are presented separately in Section 3. Section 4 collects auxiliary combinatorial lemmas. Lemma 4.2 of this section may be of independent interest.
2. Proofs. This section consists of two parts. In the first part, for reader's convenience, we collect several important facts about Hoeffding's decomposition of finite population statistics which are used in proofs below. These facts are shown in Bloznelis and Götze (2001). The second part contains proofs of Theorems 1.1 and 1.2.

Throughout this section and the next we shall assume without loss of generality that $\mathbf{E} T=0$ and $\sigma^{2}=\tau^{-2}$. For $k=1,2, \ldots$, we write $\Omega_{k}=\{1, \ldots, k\}$. By $C, c, c_{0}, c_{1}, \ldots$ we denote positive absolute constants. Given two numbers $a$ and $b>0$, we write $a \ll b$ if $|a| \leq c b$.

### 2.1. Hoeffding's decomposition of a finite population statistic

$$
\begin{equation*}
T=\mathbf{E} T+U_{1}+\cdots+U_{n} \tag{2.1}
\end{equation*}
$$

was studied by Zhao and Chen (1990) in the case of a $U$-statistic and by Bloznelis and Götze (2001) in the case of a general symmetric statistic. It was shown in the latter paper that if $n>N / 2$ then $U_{j} \equiv 0$ for $j>N-n$. Note that if $T$ is a $U$-statistic of degree $k$ [e.g., a statistic of the form (1.9)] then always $U_{j} \equiv 0$ for $j>k$. Recall that $U_{j}$ is defined in (1.2).

Given $A=\left\{i_{1}, \ldots, i_{r}\right\} \subset \Omega_{n}$ and $B=\left\{j_{1}, \ldots, j_{s}\right\} \subset \Omega_{N}$ with $1 \leq r \leq n$ write

$$
T_{A}=g_{r}\left(X_{i_{1}}, \ldots, X_{i_{r}}\right) \quad \text { and } \quad \mathbf{E}\left(T_{A} \mid B\right)=\mathbf{E}\left(T_{A} \mid X_{j_{1}}, \ldots, X_{j_{s}}\right),
$$

and denote $T_{\varnothing}=\mathbf{E} T$. By symmetry, the random variables $T_{A}$ and $T_{A^{\prime}}$ are identically distributed for any $A, A^{\prime} \subset \Omega_{N}$ such that $|A|=\left|A^{\prime}\right| \leq n$. A simple calculation shows that (1.3) extends to the following identity:

$$
\begin{equation*}
\mathbf{E}\left(T_{A} \mid B\right)=0 \quad \text { for any } A, B \subset \Omega_{N}, \text { such that }|B|<|A| \leq n . \tag{2.2}
\end{equation*}
$$

For $A, B \subset \Omega_{N}$ with $1 \leq j=|A|=|B| \leq n$ and $k=|A \cap B|$ denote

$$
\sigma_{j}^{2}=\mathbf{E} T_{A}^{2}, \quad s_{j, k}=\mathbf{E} T_{A} T_{B}
$$

Using (2.2) it is easy to show [see, e.g., Bloznelis and Götze (2001)] that

$$
\begin{equation*}
s_{j, k}=(-1)^{j-k}\binom{N-j}{j-k}^{-1} \sigma_{j}^{2}, \quad 0 \leq k \leq j \leq n^{*} \tag{2.3}
\end{equation*}
$$

Since $\mathbf{E} T=0$ we can write (2.1) in the form $T=\sum_{A \subset \Omega_{n}} T_{A}$. Similarly, for $U_{k}$ from (1.2) we have $U_{k}=\sum_{A \subset \Omega_{n},|A|=k} T_{A}$.
2.2. Proofs of Theorems 1.1 and 1.2. The expression $\exp \{i x\}$ is abbreviated as $\mathrm{e}\{x\}$. Given a complex function $H$ defined on $\mathbb{R}$, we write $\|H(x)\|=$ $\sup _{x \in \mathbb{R}}|H(x)|$. Write

$$
\delta=1-\sup \left\{\mathbf{E} \cos \left(\operatorname{tg}_{1}\left(X_{1}\right)+s\right): s \in \mathbb{R}, b_{1} \tau / \beta_{3} \leq|t| \leq \tau^{2}\right\} .
$$

It is easy to show that $\rho \leq \delta$; see Bloznelis and Götze (2000). This inequality will be used in the proof below. We also use the inequalities $1=\beta_{2} \leq \beta_{3} \leq \beta_{4}^{1 / 2}$ and $\gamma_{2} \leq \gamma_{3}^{2 / 3} \leq \gamma_{4}^{1 / 2}$ which are simple consequences of Hölder's inequality.

We can assume that for sufficiently small $c_{0}$,

$$
\begin{equation*}
\beta_{4} \leq c_{0} \tau^{2}, \quad \gamma_{2} \leq c_{0} \tau^{2} \delta^{2}, \quad \delta^{-2 / 3} \ln \tau \leq c_{0} \tau . \tag{2.4}
\end{equation*}
$$

Indeed, if (2.4) fails, the bounds (1.8) and (1.10) follow from the inequalities

$$
F(x) \leq 1 \quad \text { and } \quad|G(x)| \ll 1+\tau^{-1}\left(\beta_{4}^{1 / 2}+\gamma_{2}^{1 / 2}\right)
$$

Note that $\beta_{4} \geq 1$ and the first inequality in (2.4) imply that $\tau^{2} \geq c_{0}^{-1}$ is sufficiently large.

Proof of Theorem 1.1. The theorem is a consequence of Theorem 1.2. Write $T=U_{1}+U_{2}+U_{3}+R_{3}$, see (1.6). A Slutzky type argument gives

$$
\begin{equation*}
\Delta \leq \Delta^{\prime}+\tau^{-2}\left\|G^{(1)}(x)\right\|+\mathbf{P}\left\{\left|R_{3}\right| \geq \tau^{-2}\right\}, \tag{2.5}
\end{equation*}
$$

where $\Delta^{\prime}:=\left\|\mathbf{P}\left\{U_{1}+U_{2}+U_{3} \leq \sigma \tau x\right\}-G(x)\right\|$ satisfies, by (1.10),

$$
\Delta^{\prime} \ll \tau^{-2} \rho^{-2}\left(\beta_{4}+\gamma_{4}+\zeta\right) .
$$

Furthermore, by $(2.4),\left\|G^{(1)}(x)\right\| \ll 1$. We bound this quantity by $c \beta_{4}$, since $\beta_{4} \geq 1$. Finally, by (1.6), we have $\mathbf{P}\left\{\left|R_{3}\right| \geq \tau^{-2}\right\} \leq \delta_{4}$ and using the identity $\sigma^{2}=\tau^{-2}$ we replace $\delta_{4}$ by $\tau^{-2} \delta_{4} / \sigma^{2}$. Collecting these bounds in (2.5) we obtain (1.8).

Proof of Theorem 1.2. In view of (1.12) it suffices to prove the theorem in the case where $n \leq N / 2$. Therefore, we assume without loss of generality that $n \leq N / 2$ and $n^{*}=n$. The proof of (1.10) is complex and we first outline the main steps.

In the first step we replace $T$ by $\tilde{T}=V_{1}+\cdots+V_{m}+W$, where $W$ is a function of the observations $\left(X_{m+1}, \ldots, X_{n}\right)\left(=: \mathbb{X}_{m}\right.$ for short), and where $V_{j}=V\left(X_{j}, \mathbb{X}_{m}\right)$ is a function of $X_{j}$ and $\mathbb{X}_{m}$. Random variables $W, V_{1}, \ldots, V_{m}$ and the integer $m<n$ are specified below.

In the second step we apply Prawitz's (1972) smoothing lemma to construct upper and lower bounds for the conditional distribution function $\tilde{F}_{1}(x)=\mathbf{P}\{\tilde{T} \leq$ $\left.\sigma \tau x \mid \mathbb{X}_{m}\right\}$ :

$$
\begin{align*}
& \tilde{F}_{1}(x+) \leq 1 / 2+V \cdot P \cdot \int_{\mathbb{R}} \exp \{-i t x\} H^{-1} K(t / H) f_{1}(t) d t  \tag{2.6}\\
& \tilde{F}_{1}(x-) \geq 1 / 2-V \cdot P \cdot \int_{\mathbb{R}} \exp \{-i t x\} H^{-1} K(-t / H) f_{1}(t) d t \tag{2.7}
\end{align*}
$$

Here $f_{1}(t)=\mathbf{E}\left(\exp \{i t \tilde{T}\} \mid \mathbb{X}_{m}\right)$ denotes the conditional characteristic function of $\tilde{T} ; F(x+)=\lim _{z \downarrow x} F(z), F(x-)=\lim _{z \uparrow x} F(z)$, and V.P. denotes Cauchy's principal value. The kernel $K(s)=K_{1}(s) / 2+i K_{2}(s) /(2 \pi s)$, where

$$
K_{1}(s)=\mathbb{1}_{\{|s| \leq 1\}}(1-|s|), \quad K_{2}(s)=\mathbb{1}_{\{|s| \leq 1\}}((1-|s|) \pi s \cot (\pi s)+|s|) .
$$

The positive random variable $H=O_{P}(n)$ (a function of $\mathbb{X}_{m}$ ) is specified below. Taking the expectations of (2.6) and (2.7) we obtain upper and lower bounds for $F_{1}(x+)$ and $F_{1}(x-)$, where $F_{1}(x)=\mathbf{P}\{\tilde{T} \leq \sigma \tau x\}$. Combining these bounds with
the inversion formula

$$
G(x)=\frac{1}{2}+\frac{i}{2 \pi} \lim _{M \rightarrow \infty} V \cdot P . \int_{|t| \leq M} \exp \{-i t x\} \hat{G}(t) t^{-1} d t
$$

[see, e.g., Bentkus, Götze and van Zwet (1997)], we obtain upper bounds for $F_{1}(x+)-G(x)=: d_{1}$ and $G(x)-F_{1}(x-)=: d_{2}$ respectively. Here $\hat{G}$ denotes the Fourier-Stieltjes transform of $G$. Thus, for $d_{1}$, we have

$$
\begin{aligned}
F_{1}(x+)-G(x) & \leq \mathbf{E} I_{1}+\mathbf{E} I_{2}+\mathbf{E} I_{3}, \\
I_{1} & =\frac{1}{2} H^{-1} \int_{R} \exp \{-i x t\} K_{1}\left(\frac{t}{H}\right) f_{1}(t) d t, \\
I_{2} & =\frac{i}{2 \pi} V \cdot P \cdot \int_{R} \exp \{-i x t\} K_{2}\left(\frac{t}{H}\right)\left(f_{1}(t)-\hat{G}(t)\right) \frac{d t}{t}, \\
I_{3} & =\frac{i}{2 \pi} V \cdot P \cdot \int_{R} \exp \{-i x t\}\left(K_{2}\left(\frac{t}{H}\right)-1\right) \hat{G}(t) \frac{d t}{t} .
\end{aligned}
$$

A similar inequality holds for $d_{2}$. This step of the proof is called "data depending smoothing"; see Bentkus, Götze and van Zwet (1997).

The final step of the proof provides upper bounds for $d_{1}$ and $d_{2}$. For this purpose we construct an upper bound for $\left|f_{1}(t)\right|$, for $|t| \geq c n^{1 / 2} / \beta_{3}$. Using Cramér's condition and the multiplicative structure of $f_{1}$ (note that $\tilde{T}$ is conditionally linear given $\mathbb{X}_{m}$ ) we show that $\left|f_{1}(t)\right|$ decay exponentially in $|t|$. Furthermore, for $|t| \leq c n^{1 / 2} / \beta_{3}$ we replace the conditional characteristic function $f_{1}$ by the unconditional one $\hat{F}(t)=\mathbf{E} \exp \{i t T\}$ and construct bounds for $|\hat{F}(t)-\hat{G}(t)|$ by means of expansions of $\hat{F}(t)$ in powers observations $X_{1}, \ldots, X_{n}$.

Note that, usually, the validity of an Edgeworth expansion is proved using the conventional Berry-Eseen smoothing lemma; see, for example, Petrov (1975), Callaert, Janssen and Veraverbeke (1980), Bickel, Götze and van Zwet (1986). In the present paper (in the second step of the proof) we use Prawitz's smoothing lemma instead. This lemma is more precise in the sense that the right-hand sides of (2.6) and (2.7) do not involve absolute values of characteristic functions. Therefore, after taking the expected values of (2.6) and (2.7) we can interchange the order of integration in the right-hand sides and obtain the unconditional characteristic functions in the integrands. At the same time, the appropriate choice of the random cut-off $H$ allows to control the nonlinear part of $\tilde{T}$ so that the exponential decay of $\left|f_{1}(t)\right|$ is established using the minimal smoothness condition (Cramér's condition on the linear part of the statistic). More restrictive smoothness conditions which involve nonlinear parts of the statistic are considered in Callaert, Janssen and Veraverbeke (1980), Bickel, Götze and van Zwet (1986).

Step 1. Let $m$ denote the integer closest to the number $8 \delta^{-1} \ln \tau$. Since, by (2.4), $\tau^{2} \geq c_{0}^{-1}$ we can choose $c_{0}$ small enough so that $10 \leq m \leq n / 2$. Split $T=V+W$,
where

$$
\begin{aligned}
& V=\sum_{B \subset \Omega_{n}, B \cap \Omega_{m} \neq \varnothing} T_{B}, \quad W=\sum_{B \subset \Omega_{n}, B \cap \Omega_{m}=\varnothing} T_{B}, \\
& V=\sum_{i=1}^{m} V_{i}+\Lambda_{m}+Y_{m}+Z_{m}, \quad V_{i}=T_{\{i\}}+\xi_{i}+\eta_{m, i}, \quad \xi_{i}=\sum_{j=m+1}^{n} T_{\{i, j\}} .
\end{aligned}
$$

Here we denote

$$
\begin{align*}
\Lambda_{m} & =\sum_{B \subset \Omega_{m},|B|=2} T_{B}, \quad Z_{m}=\sum_{B \subset \Omega_{n},\left|B \cap \Omega_{m}\right| \geq 3} T_{B} \\
Y_{m} & =\sum_{B \subset \Omega_{n},\left|B \cap \Omega_{m}\right|=2,|B| \geq 3} T_{B}, \quad \eta_{m, i}=\sum_{B \subset \Omega_{n}, B \cap \Omega_{m}=\{i\},|B| \geq 3} T_{B} \tag{2.9}
\end{align*}
$$

We are going to replace $T$ by $\tilde{T}=\sum_{i=1}^{m} V_{i}+W$. Write $T=\tilde{T}+R$, where $R=\Lambda_{m}+Y_{m}+Z_{m}$. Given $\varepsilon=\delta^{-2} \tau^{-2}$, a Slutzky type argument gives

$$
\Delta \leq \Delta_{1}+\varepsilon\left\|G^{(1)}(x)\right\|+\mathbf{P}\{|R| \geq \varepsilon\}, \quad \Delta_{1}=\left\|F_{1}(x)-G(x)\right\|
$$

where $F_{1}(x)=\mathbf{P}\{\tilde{T} \leq \sigma \tau x\}$. Invoking the bounds of Lemma 4.1 and the simple bound $\mathbf{E}\left|\Lambda_{m}\right|^{3} \ll m^{6} \mathbf{E}\left|T_{\{1,2\}}\right|^{3}$, we obtain, by Chebyshev's inequality, that

$$
P\{|R| \geq \varepsilon\} \leq \mathbf{P}\left\{\left|\Lambda_{m}\right| \geq \frac{\varepsilon}{3}\right\}+\mathbf{P}\left\{\left|Y_{m}\right| \geq \frac{\varepsilon}{3}\right\}+\mathbf{P}\left\{\left|Z_{m}\right| \geq \frac{\varepsilon}{3}\right\} \ll \frac{\delta_{3} / \sigma^{2}+\gamma_{3}}{\tau^{2} \delta^{2}}
$$

Finally, we bound $\left\|G^{(1)}(x)\right\|$ as in proof of Theorem 1.1 above. We obtain

$$
\Delta \ll \Delta_{1}+\tau^{-2} \delta^{-2}\left(1+\delta_{3} / \sigma^{2}+\gamma_{3}\right)
$$

Therefore, in order to prove (1.10), it remains to bound $\Delta_{1}$. Clearly, $\Delta_{1} \leq$ $\max \left\{d_{1} ; d_{2}\right\}$, where $d_{1}=F_{1}(x+)-G(x)$ and $d_{2}=G(x)-F_{1}(x-)$. The remaining part of the proof provides bounds for $d_{1}$ and $d_{2}$.

Step 2. Let $\bar{A}=\left(A_{1}, \ldots, A_{N}\right)$ be a random permutation of $\left(x_{1}, \ldots, x_{N}\right)$ which is uniformly distributed over the class of permutations. Let $r=[(n+m) / 2]$ denote the integer part of $(n+m) / 2$. Introduce the sets $\ell_{0}=\{m+1, \ldots, n\}$, $\mathcal{L}_{0}=\{1, \ldots, N\} \backslash \ell_{0}, \mathscr{L}_{1}=\mathscr{L}_{0} \cup\{m+1, \ldots, r\}$ and $\mathscr{L}_{2}=\mathscr{L}_{0} \cup\{r+1, \ldots, n\}$. Define (random) subpopulations $\mathcal{A}_{i}=\left\{A_{k}, k \in \mathscr{\mathscr { A }}_{i}\right\}, i=0,1,2$, and given $\mathcal{A}_{i}$, let $A_{i}^{*}$ be a random variable uniformly distributed in $\mathscr{A}_{i}$.

We assume that $X_{j}=A_{j}$, for $j \in \ell_{0}$ and, given $A_{j}, j \in \ell_{0}$, the observations $X_{1}, \ldots, X_{m}$, are drawn without replacement from $\mathcal{A}_{0}$. Write

$$
\begin{gathered}
H=n \delta /\left(32 q^{-1} n\left(\Theta_{1}+\Theta_{2}\right)+1\right), \quad \Theta_{i}=\mathbf{E}^{*}\left|v_{i}\left(A_{i}^{*}\right)\right|, \quad i=1,2 \\
v_{1}(a)=\sum_{r+1 \leq j \leq n} g_{2}\left(a, A_{j}\right), \quad v_{2}(a)=\sum_{m+1 \leq j \leq r} g_{2}\left(a, A_{j}\right)
\end{gathered}
$$

Here, given $\mathscr{A}_{i}$, we denote $\mathbf{E}^{*} f\left(A_{i}^{*}\right)=\left|\mathscr{\mathscr { O }}_{i}\right|^{-1} \sum_{j \in \mathcal{g}_{i}} f\left(A_{j}\right)$, for $f: \mathcal{A}_{i} \rightarrow \mathbb{R}$.

In order to prove an upper bound for $F_{1}(x+)-G(x)$ we apply (2.8) and show that

$$
\begin{equation*}
\left|\mathbf{E} I_{1}\right|+\left|\mathbf{E}\left(I_{2}+I_{3}\right)\right| \ll \tau^{-2} \delta^{-2}\left(\beta_{4}+\gamma_{4}+c(k) \delta_{3} / \sigma^{2}\right) \tag{2.10}
\end{equation*}
$$

An upper bound for $G(x)-F_{1}(x-)$ is obtained in a similar same way.
In the remaining part of the proof we verify (2.10). Write

$$
\begin{aligned}
\hat{F}_{1}(t) & =\operatorname{Ee}\{t \tilde{T}\}, \quad H_{1}=b_{1} \tau / \beta_{3}, \\
\mathcal{Z}_{1} & =\left\{|t| \leq H_{1}\right\} \subset \mathbb{R}, \quad \mathcal{Z}_{2}=\left\{H_{1} \leq|t| \leq H\right\} \subset \mathbb{R}, \\
J_{1} & =\int_{\mathcal{Z}_{1}} \mathrm{e}\{-t x\} \frac{\hat{F}_{1}(t)-\hat{G}(t)}{t} d t, \quad J_{2}=\int_{\mathcal{Z}_{2}} \frac{\left|f_{1}(t)\right|}{|t|} d t, \\
J_{3} & =\int_{|t|>H_{1}} \frac{|\hat{G}(t)|}{|t|} d t, \quad J_{4}=\int_{\mathcal{Z}_{1}} \mathrm{e}\{-t x\} \frac{f_{1}(t)}{H} d t, \quad J_{5}=\int_{\mathcal{Z}_{2}} \frac{\left|f_{1}(t)\right|}{H} d t .
\end{aligned}
$$

Here and below we write $\mathrm{e}\{x\}$ for $\exp \{i x\}$. Using the inequality $\left|K_{1}(s)-1\right| \leq|s|$ we replace $K_{1}(s)$ by 1 in $\mathbf{E} I_{1}$ and obtain

$$
\left|\mathbf{E} I_{1}\right| \ll\left|\mathbf{E} J_{4}\right|+\mathbf{E} J_{5}+R, \quad R=\mathbf{E} H_{1}^{2} H^{-2}
$$

Similarly, using the inequality $\left|K_{2}(s)-1\right| \leq 5 s^{2}$ and the fact that $K_{2}(s)=0$ for $|s|>1$, we obtain

$$
\left|\mathbf{E}\left(I_{2}+I_{3}\right)\right| \ll\left|\mathbf{E} \tilde{J}_{1}\right|+\mathbf{E} J_{2}+J_{3}+R, \quad R=\mathbf{E} H_{1}^{2} H^{-2}
$$

where $\tilde{J}_{1}$ is defined as $J_{1}$ above, but with $\hat{F}_{1}$ replaced by $f_{1}$. Note that the change of the order of integration yields $\mathbf{E} \tilde{J}_{1}=J_{1}$.

The bounds $J_{3} \ll \tau^{-2}\left(\beta_{4}+\gamma_{2}\right)$ and $R \ll \delta^{-2} \tau^{-2}\left(1+\gamma_{2}\right)$ are proved in Bloznelis and Götze (2000). Furthermore, note that $J_{5} \leq J_{2}$. Therefore, in order to prove (2.10) it suffices to show that

$$
\begin{align*}
& \mathbf{E} J_{2} \ll \frac{\beta_{4}+\delta_{3} / \sigma^{2}}{\tau^{2}}, \quad\left|\mathbf{E} J_{4}\right| \ll \frac{1+\gamma_{2}+\delta_{3} / \sigma^{2}}{\tau^{2} \delta^{2}},  \tag{2.11}\\
& \left|J_{1}\right| \ll \frac{\beta_{4}+\gamma_{4}+c(k) \delta_{3} / \sigma^{2}}{\tau^{2} \delta^{2}} .
\end{align*}
$$

Step 3. Here we bound $\left|J_{1}\right|, \mathbf{E} J_{2}$, and $\left|\mathbf{E} J_{4}\right|$.
The bound for $\mathbf{E} J_{2}$. Given $t$, denote $\mathbb{I}_{t}=\mathbb{I}\left\{|t| \mathbf{E}^{*}\left|\eta_{m}\left(A_{0}^{*}\right)\right|<\delta / 16\right\}$, where $\eta_{m}(x)=\mathbf{E}\left(\eta_{m, 1} \mid X_{1}=x, X_{m+1}, \ldots, X_{n}\right)$. The identity $f_{1}(t)=\mathbb{I}_{t} f_{1}(t)+$ $\left(1-\mathbb{I}_{t}\right) f_{1}(t)$ combined with the inequalities

$$
1-\mathbb{I}_{t} \leq 16^{2} \delta^{-2} t^{2}\left(\mathbf{E}^{*}\left|\eta_{m}\left(A_{0}^{*}\right)\right|\right)^{2} \leq 16^{2} \delta^{-2} t^{2} \mathbf{E}^{*} \eta_{m}^{2}\left(A_{0}^{*}\right)
$$

yields $J_{2} \leq J_{2.1}+J_{2.2}$, where

$$
J_{2.1}=\int_{Z_{2}} \mathbb{I}_{t} \frac{\left|f_{1}(t)\right|}{|t|} d t \quad \text { and } \quad J_{2.2}=16^{2} \delta^{-2} \mathbf{E}^{*} \eta_{m}^{2}\left(A_{0}^{*}\right) H^{2}
$$

In order to prove the bound (2.11) for $\mathbf{E} J_{2}$ we show that

$$
\mathbf{E} J_{2.2} \ll \tau^{-2} \delta_{3} / \sigma^{2} \quad \text { and } \quad \mathbf{E} J_{2.1} \ll \beta_{3} / n^{2} .
$$

The first bound is a consequence of the inequalities $H \leq n \delta$ and $\mathbf{E E}^{*} \eta_{m}^{2}\left(A_{0}^{*}\right) \leq$ $n^{-3} \delta_{3} / \sigma^{2}$, where the latter inequality follows from (4.1) by symmetry.

The proof of the bound $\mathbf{E} J_{2.1} \ll \beta_{3} / n^{2}$ is almost the same as that of the corresponding inequality (3.12) in Bloznelis and Götze (2000). The only and minor difference is that now we add one more nonlinear term $\eta_{m}$. Namely, in the proof of (3.12) ibidem one should replace $v(a)=v_{1}(a)+v_{2}(a)$ by $\tilde{v}(a)=v(a)+\eta_{m}(a)$ and use the bound $E^{*}\left|t \eta_{m}\left(A_{0}^{*}\right)\right| \leq \delta / 16$ when estimating $\mathbf{E}^{*}\left(1+2 u_{2}\left(A_{0}^{*}\right)\right)$ in (3.17), ibidem. Indeed, the bound $E^{*}\left|t \eta_{m}\left(A_{0}^{*}\right)\right| \leq \delta / 16$ holds on the event $\left\{\mathbb{I}_{t} \neq 0\right\}$.

The bound for $\mathbf{E} J_{4}$. Define $J_{4}^{\prime}$ in the same way as $J_{4}$, but with $f_{1}(t)$ replaced by $\mathbf{E}\left(\mathrm{e}\{t \tilde{U}\} \mid \mathbb{X}_{m}\right)$, where $\tilde{U}=U-\Lambda_{m}$. We shall apply the bound $\left|\mathbf{E} J_{4}^{\prime}\right| \ll$ $n^{-1}\left(1+\gamma_{2}\right) / \delta^{2}$ which is proved in (3.20) of Bloznelis and Götze (2000). This bound and the inequality

$$
\begin{equation*}
\left|\mathbf{E} J_{4}-\mathbf{E} J_{4}^{\prime}\right| \ll \tau^{-2} \delta^{-2}\left(1+\delta_{3} / \sigma^{2}+\gamma_{2}\right) \tag{2.12}
\end{equation*}
$$

yield the bound (2.11) for $\mathbf{E} J_{4}$.
In order to prove (2.12) we write $\tilde{T}-\tilde{U}=R_{2}-Y_{m}-Z_{m}$, see (1.6) and (2.9). This identity in combination with the inequality $|\mathrm{e}\{x\}-\mathrm{e}\{y\}| \leq|x-y|$ yields $\left|\mathbf{E} J_{4}-\mathbf{E} J_{4}^{\prime}\right| \ll R$, where

$$
\begin{aligned}
R & =H_{1}^{2} \mathbf{E} H^{-1} \mathbf{E}\left(\left|R_{2}-Y_{m}-Z_{m}\right| \mid \mathbb{X}_{m}\right) \\
& \leq H_{1}^{2}\left(\mathbf{E} H^{-2}\right)^{1 / 2}\left[\left(\mathbf{E} R_{2}^{2}\right)^{1 / 2}+\left(\mathbf{E} Y_{m}^{2}\right)^{1 / 2}+\left(\mathbf{E} Z_{m}^{2}\right)^{1 / 2}\right] .
\end{aligned}
$$

In the last step we applied Cauchy-Schwarz. It follows from (1.6), (4.1) and the last inequality of (2.4) that the quantity in the brackets $[\cdots] \ll \tau^{-2} \delta^{-1} \delta_{3}^{1 / 2} / \sigma$. Finally, invoking the bound $\mathbf{E} H^{-2} \ll n^{-2} \delta^{-2}\left(1+\gamma_{2}\right)$, which is proved in (5.1) of Bloznelis and Götze (2000), we complete the proof of (2.12).

The bound for $\left|J_{1}\right|$. The bound (2.11) is a consequence of the following two bounds:

$$
\begin{align*}
\left|\ell_{Z_{1}}\left(\hat{F}_{1}-\hat{F}\right)\right| & \ll \tau^{-2} \delta^{-2}\left(1+\gamma_{2}+\delta_{3} / \sigma^{2}\right),  \tag{2.13}\\
\left|\ell_{Z_{1}}(\hat{F}-\hat{G})\right| & \ll \tau^{-2} \delta^{-2}\left(\beta_{4}+\gamma_{4}+c(k) \delta_{3} / \sigma^{2}\right) . \tag{2.14}
\end{align*}
$$

Recall that $\hat{F}(t)=\mathbf{E e}\{t T\}$. Here and below for a Borel set $\mathcal{B} \subset \mathbb{R}$ and an integrable complex function $f$, we write (for short) $\ell_{\mathcal{B}}(f)=\int_{\mathcal{B}} t^{-1} f(t) d t$.

The proof of (2.14) is rather complex. We place it in a separate Section 3 below. Note that the bound (2.14) is the only step of the proof where we essentially use the assumption that $T$ is a $U$-statistic.

Here we show (2.13). In the proof we replace $\hat{F}_{1}(t)-\hat{F}(t)$ by $f(t)=$ $\operatorname{Ee}\{t T\} i t \Lambda_{m}$ and then replace $f(t)$ by $g(t)=\operatorname{Ee}\{t U\} i t \Lambda_{m}$. Finally, we invoke the bound

$$
\begin{equation*}
\left|\ell_{Z_{1}}(g)\right| \ll\binom{m}{2} n^{-3 / 2}\left(1+\gamma_{2}\right) \ll n^{-1} \delta^{-2}\left(1+\gamma_{2}\right), \tag{2.15}
\end{equation*}
$$

which is proved in (3.38) of Bloznelis and Götze (2000). In order to show how (2.13) follows from (2.15) write $\tilde{T}=T-\Lambda_{m}-Y_{m}-Z_{m}$, see (2.9). We have $\hat{F}_{1}(t)=\operatorname{Ee}\left\{t\left(T-\Lambda_{m}-Y_{m}-Z_{m}\right)\right\}$. Expanding the exponent in powers of it $\left(Y_{m}+Z_{m}\right)$ and then in powers of it $\Lambda_{m}$ we get

$$
\left|\hat{F}_{1}(t)-\hat{F}(t)-f(t)\right| \ll \mathbf{E}\left|t Y_{m}\right|+\mathbf{E}\left|t Z_{m}\right|+t^{2} \mathbf{E} \Lambda_{m}^{2}
$$

Furthermore, the identity $T-U=R_{2}$ combined with the mean value theorem yields $|f(t)-g(t)| \ll \mathbf{E} t^{2}\left|\Lambda_{m} R_{2}\right|$. Combining these two inequalities we obtain

$$
\begin{gathered}
\left|\ell_{Z_{1}}\left(\hat{F}_{1}-\hat{F}\right)\right| \ll\left|\ell_{Z_{1}}(g)\right|+R \\
R=2 H_{1} \mathbf{E}\left|Y_{m}\right|+2 H_{1}\left|Z_{m}\right|+H_{1}^{2} \mathbf{E} \Lambda_{m}^{2}+H_{1}^{2} \mathbf{E}\left|\Lambda_{m} R_{2}\right| .
\end{gathered}
$$

Now, the bound (2.11) follows from (2.15) and the bound $R \ll \tau^{-2} \delta^{-2}\left(1+\gamma_{2}+\right.$ $\delta_{3} / \sigma^{2}$ ). The latter bound follows from the inequalities (4.1), (1.6), and the simple inequality $\mathbf{E} \Lambda_{m}^{2} \leq m^{2} n^{-3} \gamma_{2}$, via Hölder's inequality.

The proof of Theorem 1.2 is complete.
3. Expansions. Here we show (2.14). Split $\mathbb{Z}_{1}=\mathscr{B}_{1} \cup \mathscr{B}_{2}$ where $\mathscr{B}_{1}=$ $\left\{|t| \leq c_{1}\right\}$ and $\mathscr{B}_{2}=\left\{c_{1} \leq|t| \leq H_{1}\right\}$, and where $c_{1}$ is an absolute constant. Clearly, (2.14) follows from the obvious inequalities

$$
\begin{aligned}
& \ell_{Z_{1}}(\hat{F}-\hat{G}) \leq \ell_{\mathscr{B}_{1}}(\hat{F}-\hat{G})+\ell_{\mathscr{B}_{2}}(\hat{F}-\hat{G}), \\
& \ell_{B_{1}}(\hat{F}-\hat{G}) \leq \ell_{\mathscr{B}_{1}}\left(\hat{F}-\hat{F}_{U}\right)+\ell_{\mathcal{B}_{1}}\left(\hat{F}_{U}-\hat{G}\right), \quad \hat{F}_{U}(t)=\operatorname{Ee}\{t U\},
\end{aligned}
$$

and the bounds

$$
\begin{align*}
& \ell_{\mathcal{B}_{2}}(\hat{F}-\hat{G}) \ll \mathcal{R}, \quad \mathcal{R}=\frac{\beta_{4}+\gamma_{4}+c(k) \delta_{3} / \sigma^{2}}{\tau^{2} \delta^{2}},  \tag{3.1}\\
& \ell_{\mathcal{B}_{1}}\left(\hat{F}_{U}-\hat{G}\right) \ll \frac{\beta_{4}+\gamma_{4}}{\tau^{2}}, \quad \ell_{\mathcal{B}_{1}}\left(\hat{F}-\hat{F}_{U}\right) \ll \frac{1+\delta_{3} / \sigma^{2}}{\tau^{2}} . \tag{3.2}
\end{align*}
$$

The first bound of (3.2) is proved in (4.1) of Bloznelis and Götze (2000). To prove the second bound we decompose $T=U+R_{2}$, see (1.6), and apply the mean value theorem to get $\left|\hat{F}(t)-\hat{F}_{U}(t)\right| \leq \mathbf{E}\left|t R_{2}\right|$. Finally, an application of (1.6) gives $\mathbf{E}\left|R_{2}\right| \leq\left(\mathbf{E} R_{2}^{2}\right)^{1 / 2} \leq \tau^{-2} \delta_{3}^{1 / 2} / \sigma$ and, obviously, $\delta_{3}^{1 / 2} / \sigma \leq 1+\delta^{3} / \sigma^{2}$.

In order to prove (3.1) we write the characteristic function $\hat{F}(t)$ in the ErdősRényi (1959) form, see (3.4). Let $v=\left(\nu_{1}, \ldots, \nu_{N}\right)$ be i.i.d. Bernoulli random
variables independent of $\left(X_{1}, \ldots, X_{N}\right)$ and having probabilities $\mathbf{P}\left\{\nu_{1}=1\right\}=p$ and $\mathbf{P}\left\{v_{1}=0\right\}=q$. Observe, that the conditional distribution of

$$
T^{*}=\sum_{A \subset \Omega_{N},|A| \leq n} T_{A} v_{A}^{*} \quad \text { where } v_{A}^{*}=\prod_{i \in A} v_{i}
$$

given the event $\mathcal{E}=\left\{S_{v}=n\right\}$, coincides with the distribution of $T$. Here $S_{v}=$ $v_{1}+\cdots+v_{N}$. Therefore, $\hat{F}$ can be written as follows:

$$
\begin{equation*}
\hat{F}(t)=\lambda \int_{-\pi \tau}^{\pi \tau} \operatorname{Ee}\left\{t T^{*}+\tau^{-1} s\left(S_{v}-n\right)\right\} d s, \quad \lambda^{-1}=2 \pi \mathbf{P}\{\mathcal{E}\} \tau \tag{3.3}
\end{equation*}
$$

Using (2.2) it is easy to show that, for $1 \leq k \leq n$, almost surely

$$
\sum_{A \subset \Omega_{N},|A|=k} T_{A} v_{A}^{*}=\sum_{A \subset \Omega_{N},|A|=k} Q_{A}, \quad Q_{A}=T_{A} \tilde{v}_{A}, \quad \tilde{v}_{A}=\prod_{i \in A}\left(v_{i}-p\right)
$$

Therefore, almost surely, $t T^{*}+\tau^{-1} s\left(S_{v}-n\right)=S+t Q$, where

$$
S=\sum_{i=1}^{N} S_{i}, \quad S_{i}=\left(t T_{\{i\}}+\tau^{-1} s\right)\left(v_{i}-p\right), \quad Q=\sum_{A \subset \Omega_{N}, 2 \leq|A| \leq n} Q_{A}
$$

Substitution of this identity in (3.3) gives

$$
\begin{equation*}
\hat{F}(t)=\lambda \int_{-\pi \tau}^{\pi \tau} \operatorname{Ee}\{S+t Q\} d s \tag{3.4}
\end{equation*}
$$

In view of (3.4), the bound (3.1) follows from the inequalities

$$
\begin{align*}
& \int_{t \in \mathcal{B}_{2}} \lambda \int_{|s| \leq \pi \tau}\left|\mathbf{E} e\{S+t Q\}-\left(h_{1}+h_{2}\right)\right| d s \frac{d t}{|t|} \ll \mathcal{R},  \tag{3.5}\\
& \int_{t \in \mathcal{B}_{2}}\left|\lambda \int_{|s| \leq \pi \tau}\left(h_{1}+h_{2}\right) d s-\hat{G}(t)\right| \frac{d t}{|t|} \ll \mathcal{R} . \tag{3.6}
\end{align*}
$$

Here

$$
h_{1}=\operatorname{Ee}\{S\}, \quad h_{2}=i^{3}\binom{n}{2} \operatorname{Ee}\left\{S_{3}+\cdots+S_{N}\right\} V, \quad V=t Q_{\{1,2\}} S_{1} S_{2}
$$

Inequality (3.6) is proved in Bloznelis and Götze [(2000), formula (4.2)].
We are going to prove (3.5). Before the proof we introduce some notation. Given a complex valued function $f(s, t)$ we write $f \prec \mathcal{R}$ if

$$
\int_{\mathcal{B}_{2}} \frac{d t}{|t|} \int_{-\pi \tau}^{\pi \tau}|f(s, t)| d s \ll \mathcal{R}
$$

Furthermore, we write $f \sim g$ for $f-g \prec \mathcal{R}$. In view of the inequality $\lambda \leq \sqrt{2} \pi$ [see Höglund (1978)], the bound (3.5) can be written as follows: $\operatorname{Ee}\{S+t Q\} \sim$ $h_{1}+h_{2}$.

Let us prove (3.5). In what follows we assume that $t \in \mathscr{B}_{2}$ and $|s| \leq \pi \tau$. Given $s, t$ write $u=s^{2}+t^{2}$ and let (here and throughout the section) $m$ denote the integer closest to the number $c_{2} N u^{-1} \ln u$, where $c_{2}$ is an absolute constant. We choose $c_{1}$ and $c_{2}$ so that $10<m<N / 2$. Split

$$
\begin{align*}
& Q=K+L+W+Y+Z, \\
& K=\zeta+\mu, \quad \zeta=\sum_{j=1}^{m} \zeta_{j}, \quad \mu=\sum_{j=1}^{m} \mu_{j}, \\
& \zeta j=\sum_{A \cap \Omega_{m}=\{j\},|A|=2} Q_{A}, \quad \mu_{j}=\sum_{A \cap \Omega_{m}=\{j\},|A| \geq 3} Q_{A}, \quad 1 \leq j \leq m,  \tag{3.7}\\
& L=\sum_{A \subset \Omega_{m},|A|=2} Q_{A}, \quad Y=\sum_{\left|A \cap \Omega_{m}\right|=2,|A| \geq 3} Q_{A}, \\
& Z=\sum_{\left|A \cap \Omega_{m}\right| \geq 3} Q_{A}, \quad W=\sum_{A \cap \Omega_{m}=\varnothing,|A| \geq 2} Q_{A},
\end{align*}
$$

and denote $f_{1}=\mathbf{E e}\{S+t(K+W)\}$ and $f_{2}=\mathbf{E e}\{S+t(K+W)\} i t L$.
In order to prove $\mathbf{E} \exp \{S+t Q\} \sim h_{1}+h_{2}$ we shall show that

$$
\begin{align*}
& \operatorname{Ee}\{S+t Q\} \sim f_{1}+f_{2},  \tag{3.8}\\
& f_{2} \sim h_{3}, \quad h_{3}=i^{3}\binom{m}{2} \operatorname{Ee}\left\{S_{3}+\cdots+S_{N}\right\} V,  \tag{3.9}\\
& f_{1} \sim h_{1}+h_{2}-h_{3} . \tag{3.10}
\end{align*}
$$

Let us introduce some more notation. Given a sum $v=v_{1}+\ldots+v_{k}$ we write $v_{B}=\sum_{j \in B} v_{j}$, for $B \subset \Omega_{k}$. Given $B \subset \Omega_{N}$, by $\mathbf{E}_{(B)}$ we denote the conditional expectation given all the random variables, but $\nu_{j}, j \in B$. For $D \subset \Omega_{m}$, denote

$$
\mathbb{Y}_{D}=\left|\mathbf{E}_{(D)} \mathrm{e}\left\{S_{D}\right\}\right|, \quad \mathbb{Z}_{D}=\left|\mathbf{E}_{(D)} \mathrm{e}\left\{S_{D}+t \zeta_{D}\right\}\right|, \quad \mathbb{I}_{D}=\mathbb{I}\left\{\varkappa_{D}>c_{3}^{-1}\right\},
$$

$$
\begin{equation*}
\varkappa_{D}=\tau^{2}|D|^{-1} \sum_{j \in D} \zeta^{2}\left(X_{j}\right), \quad \zeta(a)=\sum_{j=m+1}^{N} g_{2}\left(a, X_{j}\right)\left(v_{j}-p\right) . \tag{3.11}
\end{equation*}
$$

Using the multiplicative structure of $\mathbb{Y}_{D}$ one can prove a sufficiently fast decay of its expected value as $u \rightarrow \infty$. More precisely, one can construct random variables $\mathbb{F}_{D}, D \subset \Omega_{N}$, of the form $\mathbb{F}_{D}=\prod_{i \in D} \tilde{u}\left(\operatorname{tg}_{1}\left(X_{i}\right)+s / \tau\right)$, where $\tilde{u} \geq 0$ is a real function, such that for $|D| \geq m / 4$ we have

$$
\begin{array}{rlr}
\mathbb{Y}_{D} & \leq \mathbb{F}_{D}, & \mathbb{Z}_{D} \leq \mathbb{I}_{D}+\mathbb{F}_{D}, \\
\mathbf{E}\left(\mathbb{F}_{D}^{2} \mid X_{i}, X_{j}\right) & \ll u^{-20} & \forall i, j \in \Omega_{N} \backslash D . \tag{3.12}
\end{array}
$$

Clearly, the latter inequality holds for the unconditional expectation as well. The proof of (3.12) and the construction of random variables $\mathbb{F}_{D}$ are provided in formulas (4.7)-(4.10) of Bloznelis and Götze (2000). Let us mention that in order to establish (3.12), one chooses the constants $c_{1}, c_{2}$ and $c_{3}$ in an appropriate way.

Split $\Omega_{m}=\Omega_{m}^{1} \cup \Omega_{m}^{2} \cup \Omega_{m}^{3}$, where $\Omega_{m}^{i}, i=1,2,3$, are disjoint consecutive intervals with cardinalities $\left|\Omega_{m}^{i}\right| \approx m / 3$. For $i \leq j$, let $\Omega_{i, j}$ denote the set of all pairs $\{l, r\}$ such that $l \in \Omega_{m}^{i}, r \in \Omega_{m}^{j}$ and $l<r$.

PROOF OF (3.8). Expanding the exponent in powers of it $Z$ and invoking (3.17) we get $\operatorname{Ee}\{S+t Q\}=f_{3}+R$, where $f_{3}=\operatorname{Ee}\{S+t(K+L+W+Y)\}$ and where

$$
|R| \leq \mathbf{E}|t Z| \leq|t|\left(\mathbf{E} Z^{2}\right)^{1 / 2} \ll|t| c_{1}^{1 / 2}(k) u^{-3 / 2} \ln ^{3 / 2} u \delta_{3}^{1 / 2} \sigma^{-1} \tau^{-2} \prec \mathcal{R}
$$

Furthermore, expanding $f_{3}$ in powers of $i t(L+Y)$ we obtain

$$
\begin{gathered}
f_{3}=f_{1}+f_{2}+f_{4}+R, \quad f_{4}=\mathbf{E e}\{S+t(K+W)\} i t Y \\
|R| \ll t^{2} \mathbf{E}(L+Y)^{2} \ll t^{2} u^{-2} \ln ^{2} u \tau^{-2}\left(\gamma_{2}+c_{1}(k) \delta_{3} / \sigma^{2}\right) \prec \mathcal{R}
\end{gathered}
$$

In the last step we invoked (3.18) and used the identity $\mathbf{E} L^{2}=\binom{m}{2} p^{2} q^{2} \tau^{-6} \gamma_{2}$. We obtain $\operatorname{Ee}\{S+t Q\} \sim f_{1}+f_{2}+f_{4}$.

It remains to prove that $f_{4} \prec \mathcal{R}$. To this end we show that $f_{4} \sim f_{5}$ and $f_{5} \prec \mathscr{R}$, where $f_{5}=\operatorname{Ee}\{S+t(\zeta+W)\}$ it $Y$. By the mean value theorem $\left|f_{4}-f_{5}\right| \leq$ $\mathbf{E} t^{2}|Y \mu|$. Furthermore, by Cauchy-Schwarz and (3.18), (3.19),

$$
\mathbf{E} t^{2}|Y \mu| \leq t^{2}\left(\mathbf{E} Y^{2}\right)^{1 / 2}\left(\mathbf{E} \mu^{2}\right)^{1 / 2} \ll t^{2} c_{1}(k) u^{-3 / 2} \ln ^{3 / 2} u \tau^{-4} \delta_{3} / \sigma^{2} \prec \mathcal{R}
$$

Therefore, $f_{4} \sim f_{5}$. In order to prove $f_{5} \prec \mathcal{R}$ we split $f_{5}=\sum_{1 \leq i \leq j \leq 3} f_{i, j}$ and show that $f_{i, j} \prec \mathcal{R}$, for every $i \leq j$. Here $f_{i, j}$ is defined in the same way as $f_{5}$, but with $Y$ replaced by $Y_{i, j}$, where $Y_{i, j}$ denotes the sum of all $Q_{A}$ such that $A \cap \Omega_{m} \in \Omega_{i, j}$. Given $i, j$ choose $r$ from $\{1,2,3\} \backslash\{i, j\}$. Note that the random variable $Y_{i, j}$ and the sequence $\left\{v_{l}, l \in \Omega_{m}^{r}\right\}$ are independent. Therefore, by (3.12),

$$
\begin{aligned}
\left|f_{i, j}\right| & \leq|t| \mathbf{E} \mathbb{Z}_{\Omega_{m}^{r}}\left|Y_{i, j}\right| \leq|t|\left(\mathbf{E} \mathbb{Z}_{\Omega_{m}^{r}}^{2}\right)^{1 / 2}\left(\mathbf{E} Y_{i, j}^{2}\right)^{1 / 2} \\
& \leq|t|\left(\mathbf{E} \mathbb{F}_{\Omega_{m}^{r}}^{2}+c_{3} \mathbf{E} \varkappa_{\Omega_{m}^{r}}\right)^{1 / 2}\left(\mathbf{E} Y_{i, j}^{2}\right)^{1 / 2}
\end{aligned}
$$

In the last step we used the simple inequality $\mathbb{I}_{D} \leq c_{3} \varkappa_{D}$, for $D=\Omega_{m}^{r}$. Note that the bound (3.18) applies to $\mathbf{E} Y_{i, j}^{2}$ as well. This bound in combination with (3.12) and (3.24) implies $f_{i, j} \prec \mathcal{R}$ thus completing the proof of (3.8).

Proof of (3.9). $\quad$ Split $W=W_{0}+W_{1}$, where

$$
\begin{equation*}
W_{0}=\sum_{A \subset \Omega_{N}: A \cap \Omega_{m}=\varnothing,|A|=2} Q_{A}, \quad W_{1}=\sum_{A \subset \Omega_{N}: A \cap \Omega_{m}=\varnothing,|A| \geq 3} Q_{A} \tag{3.13}
\end{equation*}
$$

In order to prove (3.9) we replace $f_{2}$ by $f_{6}=\mathbf{E e}\{S+t(\zeta+W)\} i t L$ and then replace $f_{6}$ by $f_{7}=\operatorname{Ee}\left\{S+t\left(\zeta+W_{0}\right)\right\} i t L$. Finally, we invoke the relation $f_{7} \sim h_{3}$ which is proved in Bloznelis and Götze [(2000), formula (4.15)].

Let us prove $f_{2} \sim f_{6}$ and $f_{6} \sim f_{7}$. By the mean value theorem, $\left|f_{2}-f_{6}\right| \leq$ $t^{2} \mathbf{E}|L \mu|$. Invoking (3.19) and the bound $\mathbf{E} L^{2} \leq m^{2} p^{2} q^{2} \tau^{-6} \gamma_{2}$ we obtain, by Cauchy-Schwarz, $t^{2} \mathbf{E}|L \mu| \prec \mathcal{R}$. Hence, $f_{2} \sim f_{6}$.

Let us prove $f_{6} \sim f_{7}$. Split $L=\sum_{1 \leq i \leq j \leq 3} L_{i, j}$, where $L_{i, j}=\sum_{A \in \Omega_{i, j}} Q_{A}$. Write $f_{6 \mid i, j}=\operatorname{Ee}\{S+t(\zeta+W)\} i t L_{i, j}$ and $f_{7 \mid i, j}=\operatorname{Ee}\left\{S+t\left(\zeta+W_{0}\right)\right\} i t L_{i, j}$. In order to prove $f_{6} \sim f_{7}$ we show that $f_{6 \mid i, j} \sim f_{7 \mid i, j}$, for every $1 \leq i \leq j \leq 3$. Given $i \leq j$, choose $r \in\{1,2,3\} \backslash\{i, j\}$ and denote $D=\Omega_{m}^{r}$. Expanding the exponent in $f_{6 \mid i, j}$ in powers of $i t W_{1}$ we obtain $f_{6 \mid i, j}=f_{7 \mid i, j}+t^{2} R$, where

$$
|R| \leq \mathbf{E}_{D}\left|L_{i, j} W_{1}\right| \leq R_{1}+R_{2}, \quad R_{1}=\mathbf{E F}_{D}\left|L_{i, j} W_{1}\right|, \quad R_{2}=\mathbf{E I}_{D}\left|L_{i, j} W_{1}\right|
$$

by (3.12). By Cauchy-Schwarz, we have

$$
\begin{equation*}
R_{1}^{2} \leq \mathbf{E} W_{1}^{2} \mathbf{E} L_{i, j}^{2} \mathbb{F}_{D}^{2}, \quad R_{2}^{2} \leq \mathbf{E} W_{1}^{2} \mathbf{E} L_{i, j}^{2} \mathbb{I}_{D} \leq \mathbf{E} W_{1}^{2} \mathbf{E} L_{i, j}^{2} c_{3} \varkappa_{D} . \tag{3.14}
\end{equation*}
$$

Fix $\left\{i_{1}, i_{2}\right\} \in \Omega_{i, j}$. By symmetry, (3.12) and (3.24),

$$
\begin{align*}
& \mathbf{E} L_{i, j}^{2} \mathbb{F}_{D}^{2}=\left|\Omega_{i, j}\right| p^{2} q^{2} \mathbf{E} g_{2}^{2}\left(X_{i_{1}}, X_{i_{2}}\right) \mathbf{E}\left(\mathbb{F}_{D}^{2} \mid i_{1}, i_{2}\right) \ll u^{-20} \tau^{-2} \gamma_{2}  \tag{3.15}\\
& \mathbf{E} L_{i, j}^{2} \varkappa_{D}=\left|\Omega_{i, j}\right| p^{2} q^{2} \mathbf{E} g_{2}^{2}\left(X_{i_{1}}, X_{i_{2}}\right) \mathbf{E}\left(\varkappa_{D} \mid i_{1}, i_{2}\right) \ll u^{-2} \ln ^{2} u \tau^{-4} \gamma_{2}^{2} . \tag{3.16}
\end{align*}
$$

Here we estimated $\left|\Omega_{i, j}\right|<m^{2}$ and $m^{2} p^{2} q^{2} \ll \tau^{4} u^{-2} \ln ^{2} u \ll \tau^{4}$. It follows from (3.14), (3.15), (3.16) and (3.20) that $t^{2} R \prec \mathcal{R}$. We obtain $f_{6 \mid i, j} \sim f_{7 \mid i, j}$ thus completing the proof of (3.9).

Proof of (3.10). In the proof we replace $f_{1}$ by $f_{8}=\mathbf{E e}\{S+t(\zeta+W)\}$ and then replace $f_{8}$ by the sum $f_{10}+f_{11}$, where $f_{10}=\mathbf{E e}\{S+t W\}$ and $f_{11}=$ $\operatorname{Ee}\{S+t W\} i t \zeta$. Finally, we replace $f_{10}$ by $f_{12}=\operatorname{Ee}\left\{S+t W_{0}\right\}$ and $f_{11}$ by $f_{13}=\mathbf{E e}\left\{S+t W_{0}\right\} i t \zeta$ [recall that $W_{0}$ is defined in (3.13)], and invoke the relation $f_{12}+f_{13} \sim h_{1}+h_{2}-h_{3}$, which is proved in Bloznelis and Götze [(2000), formulas (4.36)-(4.37)].

Let us prove $f_{1} \sim f_{8}$. Expanding in $f_{1}$ powers of $i t \mu$ we obtain

$$
f_{1}=f_{8}+f_{9}+R, \quad f_{9}=\mathbf{E e}\{S+t(\zeta+W)\} i t \mu,
$$

where $|R| \leq t^{2} \mu^{2} \prec \mathcal{R}$, by (3.19). Therefore, $f_{1} \sim f_{8}+f_{9}$. In order to show $f_{9} \prec \mathcal{R}$, split $\mu=\mu_{1}^{*}+\mu_{2}^{*}+\mu_{3}^{*}$, where $\mu_{j}^{*}=\sum_{k \in \Omega_{m}^{j}} \mu_{k}$, and write $f_{9}=f_{1}^{*}+$ $f_{2}^{*}+f_{3}^{*}$, where $f_{j}^{*}=\operatorname{Ee}\{S+t(\zeta+W)\} i t \mu_{j}^{*}$. Given $j$, we show $f_{j}^{*} \prec \mathcal{R}$. Fix $r \in\{1,2,3\} \backslash\{j\}$ and denote $D=\Omega_{m}^{r}$. By (3.12),

$$
\begin{aligned}
\left|f_{j}^{*}\right| & \leq|t| \mathbf{E} \mathbb{Z}_{D}\left|\mu_{j}^{*}\right| \leq|t|\left(\mathbf{E}\left(\mu_{j}^{*}\right)^{2}\right)^{1 / 2}\left(\mathbf{E} 2\left(\mathbb{F}_{D}^{2}+\mathbb{I}_{D}\right)\right)^{1 / 2} \\
& \leq 2|t|\left(\mathbf{E}\left(\mu_{j}^{*}\right)^{2}\right)^{1 / 2}\left(\mathbf{E} \mathbb{F}_{D}^{2}+c_{3}^{3 / 2} \mathbf{E} \varkappa_{D}^{3 / 2}\right)^{1 / 2}
\end{aligned}
$$

Here we applied Cauchy-Schwarz and the inequality $\mathbb{I}_{D} \leq c_{3}^{3 / 2} \varkappa_{D}^{3 / 2}$. Note that the bound (3.19) holds for $\mu_{j}^{*}$ as well. This bound in combination with (3.24) and (3.12) gives $f_{j}^{*} \prec \mathcal{R}$. We obtain $f_{9} \prec \mathcal{R}$, thus completing the proof of $f_{1} \sim f_{8}$.

In order to replace $f_{8}$ by $f_{10}+f_{11}$ we use the relation $f_{8} \sim f_{10}+f_{11}$. The proof of this relation is almost the same as that of the corresponding relation (4.35) in Bloznelis and Götze (2000).

It remains to show that $f_{10} \sim f_{12}$ and $f_{11} \sim f_{13}$. Expanding $f_{10}$ in powers of it $W_{1}$ we get $f_{10}=f_{12}+R$, where $|R| \leq \mathbf{E} \mathbb{Y}_{\Omega_{m}}\left|t W_{1}\right|$. It follows from (3.12) and (3.20), by Cauchy-Schwarz, that $|R| \prec \mathscr{R}$. Therefore, $f_{10} \sim f_{12}$. In order to prove $f_{11} \sim f_{13}$ split $\Omega_{m}=V_{1} \cup V_{2}$, where $V_{1} \cap V_{2}=\varnothing$ and the cardinality $\left|V_{i}\right| \approx m / 2$, for $i=1,2$, and write $\zeta=\zeta_{V_{1}}+\zeta_{V_{2}}$. Expanding $f_{11}$ in powers of it $W_{1}$, we get $f_{11}=f_{13}+R_{(1)}+R_{(2)}$, where $\left|R_{(i)}\right| \leq \mathbf{E} t^{4}\left|W_{1} \zeta_{V_{i}}\right| \mathbb{Y}_{\Omega_{m} \backslash V_{i}}$. Fix $r \in V_{1}$. By Cauchy-Schwarz and symmetry,

$$
\begin{aligned}
\left|R_{(1)}\right|^{2} & \leq t^{4} \mathbf{E} W_{1}^{2} \mathbf{E} \zeta_{V_{1}}^{2} \mathbb{Y}_{V_{2}}^{2} \\
& =t^{4} \mathbf{E} W_{1}^{2}\left|V_{1}\right|(N-m) p^{2} q^{2} \mathbf{E} g_{2}^{2}\left(X_{r}, X_{N}\right) \mathbf{E}\left(\mathbb{Y}_{V_{2}}^{2} \mid X_{r}, X_{N}\right) \\
& \ll t^{4} \tau^{-6} u^{-20} \gamma_{2} c_{1}(k) \delta_{3} / \sigma^{2}
\end{aligned}
$$

Here we applied (3.20) and (3.12). It follows that $R_{(1)} \prec \mathcal{R}$. The same bound holds for $R_{(2)}$ as well. Therefore $f_{11} \sim f_{13}$. The proof of (3.10) is complete.

Lemma 3.1. Assume that $n \leq N / 2$ and that $T$ is a $U$-statistic of degree $k$. Then

$$
\begin{align*}
& \mathbf{E} Z^{2} \leq c_{1}(k) m^{3} p^{3} q^{3} \tau^{-10} \delta_{3} \sigma^{-2}  \tag{3.17}\\
& \mathbf{E} Y^{2} \leq c_{1}(k) m^{2} p^{2} q^{2} \tau^{-8} \delta_{3} \sigma^{-2}  \tag{3.18}\\
& \mathbf{E} \mu^{2} \leq c_{1}(k) m p q \tau^{-6} \delta_{3} \sigma^{-2}  \tag{3.19}\\
& \mathbf{E} W_{1}^{2} \leq c_{1}(k) \tau^{-4} \delta_{3} \sigma^{-2} \tag{3.20}
\end{align*}
$$

where $Y, Z$ and $\mu$ are defined in (3.7), and $W_{1}$ is defined in (3.13). Here $c_{1}(k)$ denotes a constant which depends on $k$ only.

Proof. Note that our assumption that $T$ is a $U$-statistic of degree $k$ implies $\sigma_{j}^{2}=0$ for $j>k$. In the proof we use the bound which follows from (4.3), (4.4):

$$
\begin{equation*}
\sum_{j=3}^{k} a_{j} \sigma_{j}^{2} \ll \tau^{-8} \delta_{3}, \quad a_{j}=\binom{n-3}{j-3}\binom{N-n}{j-3}\binom{N-j}{j-3}^{-1} \tag{3.21}
\end{equation*}
$$

A simple calculation shows that $a_{3}=1$ and $a_{j}=b_{1} \cdots b_{j-3} b_{1}^{*} \cdots b_{j-3}^{*}$, where $b_{i}=(n-2-i) /(N-j-i+1)$ and $b_{i}^{*}=N-n-i+1$. For $i=1, \ldots, j-3$ and $j=4, \ldots, k$ we apply the following simple bounds $p \leq c(k) b_{i}$ and $q \leq$
$c(k) b_{i}^{*} / N$, for some constant $c(k)$ depending on $k$ only. These bounds imply for $j=3, \ldots, k$, that $(p q N)^{j-3} \leq c_{1}(k) a_{j}$, where $c_{1}(k)$ is a constant depending on $k$ only. Combining this bound and (3.21) we obtain

$$
\begin{equation*}
\sum_{j=3}^{k} p^{j-3} q^{j-3} N^{j-3} \sigma_{j}^{2} \ll c_{1}(k) \tau^{-8} \delta_{3} \tag{3.22}
\end{equation*}
$$

We introduce some more notation. Consider a random variable $M=\sum_{A \in \mathcal{M}} Q_{A}$, where $\mathcal{M}$ denotes a class of subsets of $\Omega_{N}$, that is, $\mathcal{M} \subset\left\{A \subset \Omega_{N}: 3 \leq|A| \leq n\right\}$. Note that $\mathbf{E} Q_{A}=0$, for every $A$ and $\mathbf{E} Q_{A}^{2}=\sigma_{j}^{2} p^{j} q^{j}$, for $|A|=j$. Since $Q_{A}$ and $Q_{B}$ are uncorrelated for $A \neq B$, we have

$$
\begin{equation*}
\mathbf{E} M^{2}=\sum_{A \in \mathcal{M}} \mathbf{E} Q_{A}^{2}=\sum_{j=3}^{n} e_{j}[M] \sigma_{j}^{2} p^{j} q^{j} \tag{3.23}
\end{equation*}
$$

where $e_{j}[M]$ denotes the number of different subsets $A \in \mathcal{M}$ of size $|A|=j$.
Let us prove (3.17). A simple calculation shows that

$$
e_{j}[Z]=\sum_{r=0}^{j-3}\binom{m}{j-r}\binom{N-m}{r}, \quad 3 \leq j \leq k
$$

Invoking the inequality $\binom{m}{j-r} \leq m^{3}\binom{m}{j-r-3}$ we obtain

$$
e_{j}[Z] \leq m^{3} \sum_{r=0}^{j-3}\binom{m}{j-r-3}\binom{N-m}{r}=m^{3}\binom{N}{j-3}
$$

by Vandermonde's convolution formula. Therefore, $e_{j}[Z] \leq m^{3} N^{j-3}$. In view of (3.23) (applied to $Z$ ) we obtain (3.17) from this inequality and (3.22).

The proof of the remaining bounds (3.18)-(3.20) is similar. We find

$$
e_{j}[Y]=\binom{m}{2}\binom{N-m}{j-2}, \quad e_{j}[\mu]=m\binom{N-m}{j-1}, \quad e_{j}\left[W_{1}\right]=\binom{N-m}{j}
$$

It follows from these identities that

$$
e_{j}[Y] \leq m^{2} N^{j-2}, \quad e_{j}[\mu] \leq m N^{j-1}, \quad e_{j}\left[W_{1}\right] \leq N^{j}
$$

Combining these bounds and (3.22) we obtain (3.18)-(3.20), thus completing the proof of the lemma.

LEMMA 3.2. For every $D \subset \Omega_{m}$, with cardinality $|D| \geq m / 4$, and for any $i, j \in \Omega_{m} \backslash D$ we have

$$
\begin{align*}
\mathbf{E}\left(\varkappa_{D} \mid X_{i}, X_{j}\right) & \ll \tau^{-2} \gamma_{2}, \\
& \mathbf{E}\left(\varkappa_{D}^{3 / 2} \mid X_{i}, X_{j}\right) \ll \tau^{-3} \gamma_{3}  \tag{3.24}\\
\mathbf{E} \varkappa_{D} & \ll \tau^{-2} \gamma_{2},
\end{align*} \quad \mathbf{E} \varkappa_{D}^{3 / 2} \ll \tau^{-3} \gamma_{3}, ~ l i
$$

where $\varkappa_{D}$ is defined in (3.11) and where $m \approx c_{2} N u^{-1} \ln u$.

Proof. Clearly the first two inequalities imply the rest ones. The first inequality is proved in Bloznelis and Götze [(2000), formula (4.22)].

Let us prove the second inequality. An application of the simple inequality $\left(|D|^{-1} \sum_{r \in D} x_{r}^{2}\right)^{3 / 2} \leq|D|^{-1} \sum_{r \in D}\left|x_{r}\right|^{3}$ to $x_{r}=\zeta\left(X_{r}\right)$ gives

$$
\varkappa_{D}^{3 / 2} \leq \tau^{3}|D|^{-1} \sum_{r \in D}\left|\zeta\left(X_{r}\right)\right|^{3} .
$$

Invoking the bound $\mathbf{E}\left(\left|\zeta\left(X_{r}\right)\right|^{3} \mid X_{i}, X_{j}\right) \ll(N p q)^{3 / 2} \mathbf{E}\left|g_{2}\left(X_{r}, X_{N}\right)\right|^{3}$ we complete the proof. In order to prove this latter bound we first apply Rosenthal's inequality to the conditional expectation of $\left|\zeta\left(X_{r}\right)\right|^{3}$ given all the random variables but $v_{m+1}, \ldots, v_{N}$ and then take the expected value given $X_{i}, X_{j}$ and apply inequalities (4.5) of Bloznelis and Götze [(2000); see also (5.4)]. The lemma is proved.
4. Combinatorial lemmas. Here we prove two lemmas. Lemma 4.1 establishes bounds for the second moments of random variables $Y_{m}, Z_{m}$ and $\eta_{m, i}$ defined in (2.9) above. Lemma 4.2 provides an auxiliary combinatorial identity.

We first introduce some more notation. For $k \leq n$ write $\Omega_{k}^{c}=\Omega_{n} \backslash \Omega_{k}$, where $\Omega_{k}=\{1, \ldots, k\}$. Let $H$ be a random variable of the form $H=\sum_{A \subset \mathscr{H}} T_{A}$, where $\mathscr{H}$ is a class of subsets of $\Omega_{N}, \mathscr{H}=\left\{A \subset \Omega_{N}: 1 \leq|A| \leq n\right\}$. Denote $U_{j}(H)=$ $\sum_{A \in \mathcal{H},|A|=j} T_{A}$ and write $e_{j}(H)=\mathbf{E} U_{j}^{2}(H) \sigma_{j}^{-2}$, for $\sigma_{j}^{2}>0$. For $\sigma_{j}^{2}=0$ put $e_{j}(H)=0$. We have

$$
H=\sum_{1 \leq j \leq n} U_{j}(H) \quad \text { and } \quad \mathbf{E} H^{2}=\sum_{1 \leq j \leq n} \mathbf{E} U_{j}^{2}(H)=\sum_{1 \leq j \leq n} e_{j}(H) \sigma_{j}^{2}
$$

where the second identity follows from the fact that $T_{A}$ and $T_{B}$ are uncorrelated for $|A| \neq|B|$; see (2.2) above.

For nonnegative integers $k, s, t, u$ such that $u \geq \min \{s, t\}+k$ denote

$$
r_{k}(s, t, u)=\sum_{v=0}^{s \wedge t}(-1)^{v+k}\binom{s}{v}\binom{t}{v}\binom{u}{v+k}^{-1} .
$$

Here $s \wedge t=\min \{s, t\}$. Recall that for $x \in \mathbb{R},\binom{x}{r}=[x]_{r} / r!$, if the integer $r \geq 0$, and $\binom{x}{r}=0$, for $r<0$. Here $[x]_{r}=x(x-1) \cdots(x-r+1)$, for $r>0$, and $[x]_{0}=1$. In particular, for nonnegative integers $s<v$, we have $\binom{s}{v}=0$.

Lemma 4.1. Assume that $100 \leq n \leq N / 2$. Given $3 \leq m \leq n$ and $i \in \Omega_{m}$, we have

$$
\begin{equation*}
\mathbf{E} Y_{m}^{2} \ll n^{-3} m^{4} \delta_{3}, \quad \mathbf{E} Z_{m}^{2} \ll n^{-4} m^{6} \delta_{3}, \quad \mathbf{E} \eta_{m, i}^{2} \ll n^{-2} \delta_{3} . \tag{4.1}
\end{equation*}
$$

Proof. In order to prove (4.1) we show that

$$
\begin{align*}
& \mathbf{E} Z_{m}^{2} \ll m^{6} \mathbf{E} Z_{3}^{2}, \quad \mathbf{E} Y_{m}^{2} \ll n m^{4} \mathbf{E} Z_{3}^{2}, \quad \mathbf{E} \eta_{m, i}^{2} \ll n^{2} \mathbf{E} Z_{3}^{2},  \tag{4.2}\\
& \mathbf{E} Z_{3}^{2} \ll n^{-4} \delta_{3} . \tag{4.3}
\end{align*}
$$

Let us show that, for $3 \leq j \leq n$,

$$
\begin{align*}
e_{j}\left(Z_{3}\right) & =\binom{n-3}{j-3} r_{0}(j-3, n-j, N-j) \\
& =\binom{n-3}{j-3}\binom{N-n}{j-3}\binom{N-j}{j-3}^{-1} \tag{4.4}
\end{align*}
$$

By symmetry,

$$
\mathbf{E} U_{j}^{2}\left(Z_{3}\right)=\binom{n-3}{j-3} \mathbf{E} T_{\Omega_{j}} U_{j}\left(Z_{3}\right), \quad \mathbf{E} T_{\Omega_{j}} U_{j}\left(Z_{3}\right)=\sum_{v=0}^{(j-3) \wedge(n-j)} M_{v} s_{j, j-v},
$$

where $M_{v}=\binom{n-j}{v}\binom{j-3}{v}$ counts the summands $T_{A}$ of the sum $U_{j}\left(Z_{3}\right)$ which satisfy $\left|A \cap \Omega_{j}\right|=j-v$. Invoking (2.3), we obtain $\mathbf{E} T_{\Omega_{j}} U_{j}\left(Z_{3}\right)=r_{0}(j-3, n-j$, $N-j) \sigma_{j}^{2}$, thus proving the first part of (4.4). The second part follows from (4.19).

Let us prove the first inequality of (4.2). Write $Z_{m}=Z_{3}+D_{4}+\cdots+D_{m}$, where $D_{s}=Z_{s}-Z_{s-1}$. By the inequality $\left(a_{1}+\cdots+a_{s}\right)^{2} \leq s\left(a_{1}^{2}+\cdots+a_{s}^{2}\right)$, we have

$$
\mathbf{E} Z_{m}^{2} \leq(m-2)\left(\mathbf{E} Z_{3}^{2}+\mathbf{E} D_{4}^{2}+\cdots+\mathbf{E} D_{m}^{2}\right)
$$

Now (4.2) follows from the inequalities $\mathbf{E} D_{s}^{2} \ll s^{4} \mathbf{E} Z_{3}^{2}$, for $4 \leq s \leq m$. To prove these inequalities we show that, for $3 \leq j \leq n$,

$$
\begin{equation*}
e_{j}\left(D_{s}\right) \ll s^{4} e_{j}\left(Z_{3}\right), \tag{4.5}
\end{equation*}
$$

Observe, that $e_{j}\left(D_{s}\right)=0$, for $n-s+3<j \leq n$, by the definition of $D_{s}$. In the case where $3 \leq j \leq n-s+3$, (4.5) follow from the identities (4.6), (4.7) and the bound (4.9); see below.

We have

$$
D_{s}=\sum_{A \subset \Omega_{s-1},|A|=2} \sum_{B \subset \Omega_{s}^{c}} T_{A \cup\{s\} \cup B} .
$$

Given $j$, this sum has $\binom{s-1}{2}\binom{n-s}{j-3}$ different summands $T_{A \cup\{s\} \cup B}$, such that $\mid A \cup$ $\{s\} \cup B \mid=j$. Fix $B_{0} \subset \Omega_{s}^{c}$ with $\left|B_{0}\right|=j-3$ and denote $A_{0}=\Omega_{2} \cup\{s\} \cup B_{0}$. By symmetry

$$
\begin{equation*}
\mathbf{E} U_{j}^{2}\left(D_{s}\right)=\binom{s-1}{2}\binom{n-s}{j-3} \mathbf{E} T_{A_{0}} U_{j}\left(D_{s}\right) . \tag{4.6}
\end{equation*}
$$

In the next step we show that

$$
\begin{equation*}
\mathbf{E} T_{A_{0}} U_{j}\left(D_{s}\right)=\left(L_{0}(j)+2(s-3) L_{1}(j)+\binom{s-3}{2} L_{2}(j)\right) \sigma_{j}^{2} \tag{4.7}
\end{equation*}
$$

where we denote $L_{i}(j)=r_{i}(j-3, \kappa, N-j)$, where $\kappa=n-s-j+3$. To this end split $U_{j}\left(D_{s}\right)=W_{0}+W_{1}+W_{2}$, where

$$
\begin{aligned}
W_{i} & =\sum_{A \in \mathcal{A}_{i}} \sum_{B \subset \Omega_{s}^{c},|B|=j-3} T_{A \cup\{s\} \cup B}, \\
\mathcal{A}_{i} & =\left\{A \subset \Omega_{s-1}:|A|=2,\left|A \cap \Omega_{2}\right|=2-i\right\},
\end{aligned}
$$

and write $\mathbf{E} T_{A_{0}} U_{j}\left(D_{s}\right)=\mathbf{E} T_{A_{0}} W_{0}+\mathbf{E} T_{A_{0}} W_{1}+\mathbf{E} T_{A_{0}} W_{2}$. Note that (4.7) follows from the identities

$$
\begin{equation*}
\mathbf{E} T_{A_{0}} W_{i}=\left|\mathcal{A}_{i}\right| L_{i}(j) \sigma_{j}^{2}, \quad i=0,1,2 \tag{4.8}
\end{equation*}
$$

which we are going to prove now. Denote $H_{0}=\{1,2\}, H_{1}=\{1,3\}, H_{2}=\{3,4\}$. By symmetry, for $i=0,1,2$,

$$
\mathbf{E} T_{A_{0}} W_{i}=\left|\mathscr{A}_{i}\right| \mathbf{E} T_{A_{0}} \sum_{B \subset \Omega_{s}^{c},|B|=j-3} T_{H_{i} \cup\{s\} \cup B}=\left|\mathscr{A}_{i}\right| \sum_{v=0}^{(j-3) \wedge \kappa} M_{v} s_{j, j-v-i} .
$$

Here $M_{v}=\binom{\kappa}{v}\binom{j-3}{v}$ counts the subsets $B \subset \Omega_{s}^{c}$ such that $\left|B \cap B_{0}\right|=j-3-v$. Invoking (2.3) we obtain (4.8).

We complete the proof of (4.5), by showing that, for $3 \leq j \leq n-s+3$,

$$
\begin{equation*}
L_{i}^{\prime}(j) \ll 1 \quad \text { where } L_{i}^{\prime}(j):=\binom{n-s}{j-3} \frac{\left|L_{i}(j)\right|}{e_{j}\left(Z_{3}\right)}, \quad i=0,1,2 . \tag{4.9}
\end{equation*}
$$

To evaluate $L_{i}^{\prime}(j)$ we use the expression (4.4) for $e_{j}\left(Z_{3}\right)$ and invoke the formulas (4.21) for $L_{i}(j)$. For $i=0$ a simple calculation shows that

$$
L_{0}^{\prime}(j)=\frac{[n-s]_{j-3}}{[N-n]_{j-3}} \frac{[N-n+s-3]_{j-3}}{[n-3]_{j-3}}=\prod_{r=0}^{j-4} \frac{x_{r}}{y_{r}} \frac{y_{r}+s-3}{x_{r}+s-3},
$$

where we denote $x_{r}=n-s-r$ and $y_{r}=N-n-r$. Now the inequality $L_{0}^{\prime}(j) \leq 1$ follows from the inequalities $x_{r} \leq y_{r}$, which are consequences of the inequality $n \leq N / 2$.

For $i=1,2$ the proof of (4.9) is similar.
Let us prove the second inequality of (4.2). To this end we shall show that

$$
\begin{equation*}
e_{j}\left(Y_{m}\right) \ll n m^{4} e_{j}\left(Z_{3}\right), \quad 3 \leq j \leq n \tag{4.10}
\end{equation*}
$$

Note that (by the definition of $Y_{m}$ ) $e_{j}\left(Y_{m}\right)=0$, for $j>n-m+2$. Let us prove (4.10), for $3 \leq j \leq n-m+2$. Given $j$, fix $B_{0} \subset \Omega_{m}^{c}$, with $\left|B_{0}\right|=j-2$. By symmetry,

$$
\begin{equation*}
\mathbf{E} U_{j}^{2}\left(Y_{m}\right)=\binom{m}{2}\binom{n-m}{j-2} \mathbf{E} T_{\Omega_{2} \cup B_{0}} U_{j}\left(Y_{m}\right) \tag{4.11}
\end{equation*}
$$

Proceeding as in the proof of (4.7) above, we obtain

$$
\begin{equation*}
\mathbf{E} T_{\Omega_{2} \cup B_{0}} U_{j}\left(Y_{m}\right)=\left(L_{0}(j)+2(m-2) L_{1}(j)+\binom{m-2}{2} L_{2}(j)\right) \sigma_{j}^{2} \tag{4.12}
\end{equation*}
$$

where $L_{i}(j)=r_{i}(j-2, n-m-j+2, N-j)$, for $i=0,1,2$. Furthermore, arguing as in proof of (4.9) we obtain

$$
\begin{equation*}
\binom{n-m}{j-2} L_{i}(j) \ll n e_{j}\left(Z_{3}\right) \quad \text { for } i=0,1,2 . \tag{4.13}
\end{equation*}
$$

Finally, combining (4.11)-(4.13) we get $\mathbf{E} U_{j}^{2}\left(Y_{m}\right) \ll n m^{4} e_{j}\left(Z_{3}\right) \sigma_{j}^{2}$. This bound implies (4.10) thus completing the proof of the second inequality of (4.2)

In order to prove the last inequality of (4.2) we shall show that, for $3 \leq j \leq n$,

$$
\begin{equation*}
e_{j}\left(\eta_{m, i}\right) \leq n^{2} e_{j}\left(Z_{3}\right) \tag{4.14}
\end{equation*}
$$

Note that (by the definition of $\left.\eta_{m, i}\right) e_{j}\left(\eta_{m, i}\right)=0$, for $j>n-m+1$. Let us prove (4.14), for $3 \leq j \leq n-m+1$. Given $j$, fix $B_{0} \subset \Omega_{m}^{c}$, with $\left|B_{0}\right|=j-1$. By symmetry,

$$
\begin{equation*}
\mathbf{E} U_{j}^{2}\left(\eta_{m, i}\right)=\binom{n-m}{j-1} \mathbf{E} T_{\{i\} \cup B_{0}} U_{j}\left(\eta_{m, i}\right) . \tag{4.15}
\end{equation*}
$$

Denote $\kappa=n-m-j+1$. A direct calculation shows that

$$
\mathbf{E} T_{\{i\} \cup B_{0}} U_{j}\left(\eta_{m, i}\right)=\sum_{v=0}^{(j-1) \wedge \kappa}\binom{j-1}{v}\binom{\kappa}{v} s_{j, j-v}=r_{0}(j-1, \kappa, N-j) \sigma_{j}^{2}
$$

where in the last step we invoke (2.3). Furthermore, proceeding as in the proof of (4.9) we obtain

$$
\begin{equation*}
\binom{n-m}{j-1} r_{0}(j-1, \kappa, N-j) \leq n^{2} e_{j}\left(Z_{3}\right) . \tag{4.16}
\end{equation*}
$$

Now (4.14) follows from (4.15) and (4.16).
Proof of (4.3). Note that the inequality $n \leq N / 2$ implies $\tau^{2} \geq n / 2$. Therefore, in order to prove (4.3) it suffices to show that $\mathbf{E} Z_{3}^{2} \ll \mathbf{E}\left(\mathbb{D}_{3} T\right)^{2}$. For this purpose we show that

$$
\begin{equation*}
e_{j}\left(Z_{3}\right) \ll e_{j}\left(\mathbb{D}_{3} T\right), \quad 3 \leq j \leq n . \tag{4.17}
\end{equation*}
$$

We invoke the formula for $\mathbf{E} U_{j}^{2}\left(\mathbb{D}_{i} T\right)$ provided in Lemma 2 of Bloznelis and Götze (2001):

$$
\mathbf{E} U_{j}^{2}\left(\mathbb{D}_{i} T\right)=\frac{\binom{n-i}{j-i}\binom{N-n-i}{j-i}}{\binom{N-i-j}{j-i}} \frac{N-j+1}{N-i-j+1} 2^{i} \sigma_{j}^{2} .
$$

Combining this formula and (4.4) we find $\frac{e_{j}\left(Z_{3}\right)}{e_{j}\left(\mathbb{D}_{3} T\right)}=A B C$ where

$$
A=\frac{[N-n]_{3}}{[N-j]_{3}}, \quad B=\frac{[N-2 j+3]_{3}}{[N-n-j+3]_{3}}, \quad C=2^{-3} \frac{N-j-2}{N-j+1}
$$

Inequality (4.17) follows from the inequalities $A \leq 1, C \leq 2^{-3}$ and $B \leq 2^{3}$. The first two inequalities are obvious. In order to show the last one we write $j=n-\varepsilon$ and use the fact that $\varepsilon \geq 0$. The lemma is proved.

In the remaining part of the section we evaluate the coefficients $r_{k}(s, t, u)$. Using the identity [see Feller (1968), Chapter II]

$$
\begin{equation*}
\sum_{v}(-1)^{v}\binom{a}{v}\binom{u-v}{t}=\binom{u-a}{u-t}, \quad a, t, u \in\{0,1,2, \ldots\} \tag{4.18}
\end{equation*}
$$

Zhao and Chen (1990) showed that for $u \geq s \wedge t$ and $s \geq t$

$$
\begin{equation*}
r_{0}(s, t, u)=\binom{u-s}{t}\binom{u}{t}^{-1} \tag{4.19}
\end{equation*}
$$

Given integers $0 \leq s \leq t$, let $l(t, s)$ denote the coefficients of the expansion

$$
\begin{equation*}
[v+t]_{t}=l(t, t)[v]_{t}+l(t, t-1)[v]_{t-1}+\cdots+l(t, 0)[v]_{0} \tag{4.20}
\end{equation*}
$$

LEMMA 4.2. Let $k, s, t, u \in\{0,1,2, \ldots\}$. For $u \geq s \wedge t+k$, we have

$$
\begin{equation*}
r_{k}(s, t, u)=\sum_{r=0}^{k} l(k, r)(-1)^{r+k} A_{k, r} \tag{4.21}
\end{equation*}
$$

where

$$
A_{k, r}= \begin{cases}0, & \text { for } r>s \wedge t \\ 0, & \text { for } u<s+t+k-r \\ \frac{(u-s-k)!(u-t-k)![s]_{r}[t]_{r}}{(u-s-t-k+r)!u!}, & \text { otherwise }\end{cases}
$$

Clearly, the numbers $l(i, j)$ can be expressed by Stirling numbers. A direct calculation shows that

$$
\begin{array}{lll}
l(0,0)=1 ; & l(1,0)=1, & l(1,1)=1 \\
l(2,0)=2, & l(2,1)=4, & l(2,2)=1 \\
l(3,0)=6, & l(3,1)=18, & l(3,2)=9,
\end{array} \quad l(3,3)=1
$$

Proof of Lemma 4.2. Write $a=\min \{s, t\}$ and $b=\max \{s, t\}$. We have

$$
\begin{equation*}
r_{k}(s, t, u)=\sum_{v=0}^{a}(-1)^{v+k}\binom{b}{v} M_{v} \quad \text { where } M_{v}=\binom{a}{v}\binom{u}{v+k}^{-1} \tag{4.22}
\end{equation*}
$$

A simple calculation shows that

$$
M_{v}=[v+k]_{k}\binom{u-k-v}{u-k-a} w_{k}(a, u), \quad w_{k}(a, u)=\binom{u-k}{a}^{-1}[u]_{k}^{-1} .
$$

Invoking the expansion (4.20), for the function $v \rightarrow[v+k]_{k}$, we obtain an expression for $M_{v}$. Substituting this expression in (4.22) we get

$$
r_{k}(s, t, u)=w_{k}(a, u) \sum_{r=0}^{k} l(k, r) S_{r}, \quad S_{r}=\sum_{v=0}^{a}(-1)^{v+k}\binom{b}{v}\binom{u-k-v}{u-k-a}[v]_{r} .
$$

We complete the proof of (4.21) by showing that, for $0 \leq r \leq k$,

$$
\begin{align*}
& S_{r}=(-1)^{r+k}[b]_{r}\binom{u-b-k}{a-r}, \\
& {[b]_{r}\binom{u-b-k}{a-r} w_{k}(a, u)=A_{k, r} .} \tag{4.23}
\end{align*}
$$

Note that $[v]_{r}=0$, for $v<r$. For $r \leq v \leq b$, we have $[v]_{r}\binom{b}{v}=[b]_{r}\binom{b-r}{v-r}$. Therefore, denoting $v^{\prime}=v-r$, we can write

$$
S_{r}=\sum_{v^{\prime}=0}^{a-r}(-1)^{v^{\prime}+r+k}[b]_{r}\binom{b-r}{v^{\prime}}\binom{u-k-r-v^{\prime}}{u-k-a} .
$$

Finally, invoking (4.18) we obtain the first identity of (4.23). The second identity is trivial.
