

## PERMUTATIONS OF THE POSITIVE INTEGERS WITH RESTRICTIONS ON THE SEQUENCE OF DIFFERENCES

PETER J. SLATER AND WILLIAM YSLAS VÉLEZ

**Let  $\{a_k\}$  be a sequence of positive integers and  $d_k = |a_{k+1} - a_k|$ . We say that  $\{a_k\}$  is a permutation if every positive integer appears once and only once in the sequence,  $\{a_k\}$ . We prove the following: Let  $\{m_i\}$  be any sequence of positive integers, then there exists a permutation  $\{a_k\}$  such that  $|\{k | d_k = i\}| = m_i$ .**

By a permutation  $\{a_k | k \in N\}$ , where  $N$  denotes the set of positive integers, we shall mean a sequence of positive integers such that every element of  $N$  appears once and only once in the sequence  $\{a_k | k \in N\}$ . Set  $d_k = |a_{k+1} - a_k|$ . The purpose of this paper is to answer, in the affirmative, two questions which were raised by Roger Entringer at the University of New Mexico.

*Question 1.* Can one construct a permutation  $\{a_k | k \in N\}$  such that given any interger  $n$ ,  $|\{k | d_k = n\}| \leq C$ , where  $C$  is some fixed constant which is independent of  $n$ ?

*Question 2.* Can one construct a permutation  $\{a_k | k \in N\}$  such that  $\{d_k | k \in N\}$  is also a permutation?

These questions are similar in nature to a problem described in [2] as having been solved by M. Hall. A solution by J. Browkin appears in [1], and the problem is to find a subset  $A$  of  $N$  such that every natural number is the difference of precisely one pair of numbers of the set  $A$ . Note that in this problem one considers all differences and not just differences formed by adjacent members in a sequence.

Let us consider the following procedure for constructing a sequence. Let  $a_1 = 1, a_2 = 2$ . We define  $a_3$  as follows: Let  $a_3$  be the smallest integer, which has not already appeared in the sequence, such that the difference  $|a_3 - a_2|$  has also not appeared. Clearly,  $a_3 = 4$ . Assume that  $a_1, a_2, \dots, a_t$  have been defined in this way. Define  $a_{t+1}$  by the following conditions: (i)  $|a_{t+1} - a_t| \neq d_i, i < t$ , (ii)  $a_{t+1} \neq a_i, i < t + 1$ , and (iii)  $a_{t+1}$  is the smallest positive integer with properties (i) and (ii).

Clearly, every integer appears at most once in the sequences  $\{a_k | k \in N\}$  and  $\{d_k | k \in N\}$ . But are these sequences permutations? The next theorem settles this question for the sequence  $\{a_k | k \in N\}$ .

**THEOREM 1.** *The sequence,  $\{a_k | k \in N\}$ , constructed above is a permutation.*

*Proof.* Assume that this sequence is not a permutation. Let  $i$  be the smallest integer which does not appear in the sequence. Choose  $k$  so that  $\{1, 2, \dots, i-1\} \subset \{a_1, \dots, a_k\}$ . Choose subscripts  $k_1, k_2, \dots, k_{i+1}$  such that  $k+1 \leq k_1 < k_2 < \dots < k_{i+1}$  and  $a_{k_j} > a_l$ , for  $l < k_j$ , that is,  $a_{k_j}$  is the largest integer to appear in  $\{a_1, \dots, a_{k_j}\}$ . Let  $M = \max\{d_j \mid j = 1, \dots, k_{i+1} - 1\}$ ,  $M_1 = \max\{d_j \mid j = 1, \dots, k_1 - 1\}$ ,  $M_2 = \max\{d_j \mid j = k - 1, \dots, k_{i+1} - 1\}$ . Then  $M = \max\{M_1, M_2\}$ . But  $M_1 \leq a_{k_1} - 1$  and  $M_2 \leq a_{k_{i+1}} - (i+1)$ , since the smallest integer appearing in the sequence  $\{a_{k_1}, a_{k_2}, \dots, a_{k_{i+1}}\}$  is larger than or equal to  $(i+1)$ . Hence  $M \leq \max\{a_{k_1} - 1, a_{k_{i+1}} - (i+1)\}$ . But  $a_{k_1} - 1 \leq a_{k_2} - 2 \leq \dots \leq a_{k_{i+1}} - (i+1)$ . So  $M \leq a_{k_{i+1}} - (i+1) < a_{k_{i+1}} - i$ . Hence  $a_{k_{i+1}} - i > d_j$ ,  $j = 1, \dots, k_{i+1} - 1$ , and  $i$  is the smallest integer which has not been used, so we must have that  $a_{k_{i+1}+1} = i$ , which is a contradiction.

We have not been able to determine whether or not the sequence  $\{d_k \mid k \in N\}$  is a permutation.

We next consider another way of constructing permutations so that the differences are also a permutation.

We say that  $\{a_1, \dots, a_t\}$  has property 1 if the  $a_i$  are distinct and the  $d_i = |a_{i+1} - a_i|$ ,  $i = 1, \dots, t-1$ , are also distinct.

Let  $i_t$  be the smallest integer not appearing in the set  $\{a_1, \dots, a_t\}$ ,  $e_t$  is the smallest integer not appearing in the set  $\{d_1, \dots, d_{t-1}\}$ ,  $I_t = \max\{a_1, \dots, a_t\}$ ,  $E_t = \max\{d_1, \dots, d_{t-1}\}$ . Clearly  $E_t < I_t$ .

REMARK. Note that either  $e_t < E_t$  or  $e_t = E_t + 1$ . In either case we have that  $e_t \leq I_t$ .

Rule 1. Set  $a_{t+1} = 2I_t + 1$ . If  $e_t \leq i_t$ , then set  $a_{t+2} = a_{t+1} - e_t$ . If  $e_t > i_t$ , then set  $a_{t+2} = i_t$ .

LEMMA 1. If  $\{a_1, \dots, a_t\}$  has property 1 and  $a_{t+1}, a_{t+2}$  are constructed according to Rule 1, then  $\{a_1, \dots, a_t, a_{t+1}, a_{t+2}\}$  also has property 1.

*Proof.* Clearly  $a_{t+1} \cap \{a_1, \dots, a_t\} = \emptyset$  and  $d_t = a_{t+1} - a_t = 2I_t + 1 - a_t = I_t + 1 + (I_t - a_t) \geq I_t + 1 > E_t$ , so  $d_t \cap \{d_1, \dots, d_{t-1}\} = \emptyset$ .

Assume that  $e_t \leq i_t$ . Then  $a_{t+2} = 2I_t + 1 - e_t = I_t + 1 + (I_t - e_t) \geq I_t + 1$ . Hence  $\{a_{t+2}\} \cap \{a_1, \dots, a_t\} = \emptyset$ , so  $\{a_1, \dots, a_t, a_{t+1}, a_{t+2}\}$  are  $t+2$  distinct integers. Further  $d_{t+1} = |a_{t+2} - a_{t+1}| = e_t$ , so  $\{d_1, \dots, d_{t+1}\}$  are  $t+1$  distinct differences, hence  $\{a_1, \dots, a_{t+2}\}$  has property 1.

Assume that  $i_t < e_t$ . Then  $a_{t+2} = i_t$ , so  $\{a_1, \dots, a_{t+2}\}$  are  $t+2$  distinct integers. Further  $d_{t+1} = 2I_t + 1 - i_t = I_t + 1 + (I_t - i_t) > (I_t + 1) + (I_t - e_t) \geq I_t + 1 > E_t$ . So  $\{d_{t+1}\} \cap \{d_1, \dots, d_t\} = \emptyset$ , hence  $\{a_1, \dots, a_t, a_{t+1}, a_{t+2}\}$  has property 1.

Since  $\{a_1, \dots, a_{t+2}\}$  now has property 1, we can apply Rule 1 to this sequence and obtain the sequence  $\{a_1, \dots, a_{t+4}\}$ , which again has property 1.

**THEOREM 2.** *Let  $\{a_1, \dots, a_t\}$  have property 1 and assume that the infinite sequence  $\{a_1, \dots, a_t, a_{t+1}, \dots\}$  is obtained from  $\{a_1, \dots, a_t\}$  by applying Rule 1 successively, then the sequences  $\{a_k | k \in N\}$  and  $\{d_k | k \in N\}$  are both permutations.*

*Proof.* If  $e_t \leq i_t$ , then  $d_{t+1} = e_t$ . Hence the smallest difference which has not appeared in  $\{d_1, \dots, d_{t+1}\}$  is larger than  $e_t$ , while  $i_t$  is still the smallest integer which has not appeared in  $\{a_1, \dots, a_{t+2}\}$ . If  $i_t < e_t$ , then just the opposite happens. We have that  $a_{t+2} = i_t$  while the smallest difference which has not appeared in  $\{d_1, \dots, d_{t+1}\}$  is still  $e_t$ . From these remarks the theorem follows by induction.

Let  $\{m_1, m_2, \dots\}$  be any sequence of positive integers. Then by a slight variation we can obtain a permutation  $\{a_k | k \in N\}$  such that  $|\{i | d_i = j\}| = m_j$ .

We say that  $\{a_1, \dots, a_t\}$  has property 2 if the  $a_i$  are distinct and  $|\{i | d_i = j, i < t\}| \leq m_j$ , for all  $j$ .

Let  $i_t, I_t, E_t$  be defined as before. Let  $e_t$  be the smallest integer such that  $|\{i | d_i = j, i < t\}| = m_j$ , for  $j < e_t$ , and  $|\{i | d_i = e_t, i < t\}| < m_{e_t}$ . As before, we have that  $E_t < I_t$  and  $e_t \leq I_t$ .

**LEMMA 2.** *Assume that  $\{a_1, \dots, a_t\}$  has property 2 and that  $a_{t+1}, a_{t+2}$  are defined according to Rule 1, then  $\{a_1, \dots, a_t, a_{t+1}, a_{t+2}\}$  also has property 2.*

*Proof.* The proof is exactly the same as Lemma 1.

**THEOREM 3.** *Let  $\{m_1, m_2, \dots\}$  be any infinite sequence of positive integers and let  $\{a_1, a_2, \dots, a_t\}$  be a sequence which satisfies property 2. If the sequence  $\{a_1, \dots, a_t, a_{t+1}, \dots\}$  is obtained by successively applying Rule 1, then this sequence is a permutation and it also has the property that  $|\{i | d_i = j\}| = m_j$ .*

*Proof.* The proof follows by induction.

**REMARK.** There are sequences which satisfy property 2, for example,  $\{a_1, a_2\}$ , where  $a_1 \neq a_2$ .
