We study the combinatoric convolution sums involving odd divisor functions, their relations to Bernoulli numbers, and some interesting applications.

1. Introduction

The Bernoulli polynomials $B_k(x)$, which are usually defined by the exponential generating function

$$\frac{te^{xt}}{e^t - 1} = \sum_{k=0}^{\infty} B_k(x) \frac{t^k}{k!}, \quad (1)$$

play an important role in different areas of mathematics, including number theory and the theory of finite differences. It is well known that $B_k = B_k(0)$ are rational numbers. It can be shown that $B_{2k+1} = 0$ for $k \geq 1$ and is alternatively positive and negative for even k . The B_k are called Bernoulli numbers. Let \mathbb{N} denote the set of positive integers. Further, let $N, d, k \in \mathbb{N}$, where $s, r \in \mathbb{N} \cup \{0\}$. Throughout this paper, we define divisor functions as follows:

$$\begin{aligned} \sigma_s(n) &= \sum_{d|n} d^s, & \sigma_{s,r}(n; m) &= \sum_{\substack{d|n \\ d \equiv r \pmod{m}}} d^s, \\ \tilde{\sigma}_s(n) &= \sum_{d|n} (-1)^{d-1} d^s, & \sigma_s^*(n) &:= \sum_{\substack{d|n \\ n/d \text{ odd}}} d^s. \end{aligned} \quad (2)$$

We also make use of the following convention:

$$\sigma_s(n) = 0 \quad \text{if } n \notin \mathbb{Z} \text{ or } n \leq 0. \quad (3)$$

Ramanujan [1] proved that

$$\begin{aligned} \sum_{m=1}^{n-1} \sigma_1(m) \sigma_1(n-m) &= \frac{1}{12} (5\sigma_3(n) + (1-6n)\sigma_1(n)), \\ \sum_{m=1}^{n-1} \sigma_1(m) \sigma_3(n-m) &= \frac{1}{240} [21\sigma_5(n) + (10-30n)\sigma_3(n) - \sigma_1(n)] \end{aligned} \quad (4)$$

using elementary arguments.

Let \mathfrak{H} be the complex upper half plane $\{z \in \mathbb{C} : \text{Im}(z) > 0\}$ and let q be $e^{2\pi iz}$ for $z \in \mathfrak{H}$. Denote $\eta(z)$ by the Dedekind η -function

$$\eta(z) = q^{1/24} \prod_{n \geq 1} (1 - q^n) \quad (5)$$

and $c_6(n)$ by the n th coefficient of $(\eta(z)\eta(2z)\eta(3z)\eta(6z))^2$. Alaca and Williams [2] proved that

$$\begin{aligned} \sum_{\substack{(l,m) \in \mathbb{N}^2 \\ 2l+3m=n}} \sigma_1(l) \sigma_1(m) \\ = \frac{1}{120} \sigma_3(n) + \frac{1}{30} \sigma_3\left(\frac{n}{2}\right) \end{aligned}$$

$$\begin{aligned}
& + \frac{3}{40} \sigma_3 \left(\frac{n}{3} \right) + \frac{3}{10} \sigma_3 \left(\frac{n}{6} \right) + \left(\frac{1}{24} - \frac{n}{12} \right) \sigma_1 \left(\frac{n}{2} \right) \\
& + \left(\frac{1}{24} - \frac{n}{8} \right) \sigma_1 \left(\frac{n}{3} \right) - \frac{1}{120} c_6(n).
\end{aligned} \tag{6}$$

It turns out that we need not only divisor functions but also the coefficients of certain modular functions. For other divisor functions, Hahn [3] showed that

$$16 \sum_{m=1}^{n-1} \tilde{\sigma}_1(m) \tilde{\sigma}_3(n-m) = -\tilde{\sigma}_5(n) + 2(n-1)\tilde{\sigma}_3(n) + \tilde{\sigma}_1(n) \tag{7}$$

and Glaisher [4–6] extended Besgue's formula by replacing $\sigma_1(n)$ in the convolution sum in (4) by other sums $\sigma^*(n)$; for example,

$$\begin{aligned}
24 \sum_{m=1}^{n-1} \sigma_1^*(m) \sigma_1^*(n-m) &= 6\sigma_3(n) - 6\sigma_3 \left(\frac{n}{2} \right) \\
&- 6n\sigma_1(n) + 6n\sigma_1 \left(\frac{n}{2} \right).
\end{aligned} \tag{8}$$

Recently, the combinatorial convolution sum is studied [7–10]. In [10] Williams proved the following.

Proposition 1. Let $k, n \in \mathbb{N}$ and $n \geq 2$. Then

$$\begin{aligned}
&\sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \sigma_{2k-2s-1}(m) \sigma_{2s+1}(n-m) \\
&= \frac{2k+3}{4k+2} \sigma_{2k+1}(n) + \left(\frac{k}{6} - n \right) \sigma_{2k-1}(n) \\
&+ \frac{1}{2k+1} \sum_{j=2}^k \binom{2k+1}{2j} B_{2j} \sigma_{2k+1-2j}(n).
\end{aligned} \tag{9}$$

Cho et al. found out the linear sum for combinatorial convolution sum of $\sigma_l(m; i, N)$ in [7].

Proposition 2. For $k, N \in \mathbb{N}$ and $N \geq 3$, one has

$$\begin{aligned}
&\sum_{r=0}^{2k} \binom{2k}{r} \sum_{i=1}^{[(N-1)/2]} \sum_{m=1}^{n-1} \sigma_{2k-r}(m; i, N) \sigma_r(n-m; i, N) \\
&= \sigma_{2k+1}^*(n; N) - \frac{2}{N} n \sigma_{2k-1}^*(n; N) \\
&- \frac{1}{N} \sum_{i=1}^{[(N-1)/2]} (N-2i) \sigma_{2k}(n; i, N) \\
&- \frac{1+(-1)^N}{2} \left(\sigma_{2k+1}^* \left(\frac{2n}{N}; 2 \right) - \frac{2}{N} n \sigma_{2k-1}^* \left(\frac{2n}{N}; 2 \right) \right),
\end{aligned} \tag{10}$$

where

$$\begin{aligned}
\sigma_r(n; i, N) &= \sum_{\substack{d|n \\ n/d=i(N)}} d^r - (-1)^r \sum_{\substack{d|n \\ n/d=-i(N)}} d^r, \\
\sigma_r^*(n; N) &= \sum_{\substack{d|n \\ n/d \neq 0(N)}} d^r = \sigma_r(n) - \sigma_r \left(\frac{n}{N} \right).
\end{aligned} \tag{11}$$

Denote \tilde{B}_k by $\sum_{j=0}^k \binom{k}{j} 2^j B_j = 2^k B_k(1/2)$. The generating function $2te^t/(e^{2t}-1)$ of \tilde{B}_k is an even function and \tilde{B}_k is zero for all odd positive integer k . The aim of this paper is to study two combinatorial convolution sums of the analogous type of Proposition 2. When we write the convolution sums as linear sum of divisor function, in the result by Williams the coefficients are $B_k = B_k(0)$ and ours are $B_k(1/2)$. More precisely, we prove the following theorems.

Theorem 3. For $k, n \in \mathbb{N}$ and $n \geq 2$,

$$\begin{aligned}
&\sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(n-m; 2) \\
&= 2^{2k-1} \sigma_{2k+1} \left(\frac{n}{2} \right) + \frac{1}{4k+2} \sum_{i=0}^k \binom{2k+1}{2i+1} \\
&\quad \times \tilde{B}_{2k-2i} \sigma_{2i+1,1}(n; 2).
\end{aligned} \tag{12}$$

Equation (7) is a special case when $k = 2$ for the following theorem because $\tilde{B}_4 = 14/30$ and $B_4 = -1/30$.

Theorem 4. For $k, n \in \mathbb{N}$ and $n \geq 2$,

$$\begin{aligned}
&\sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \tilde{\sigma}_{2k-2s-1}(m) \tilde{\sigma}_{2s+1}(n-m) \\
&= -\frac{1}{2} \tilde{\sigma}_{2k+1}(n) + \left(n - \frac{k}{2} \right) \tilde{\sigma}_{2k-1}(n) \\
&+ \frac{1}{4k+2} \sum_{i=0}^{k-2} \binom{2k+1}{2i+1} \\
&\quad \times \left(\tilde{B}_{2k-2i} + (2^{2k-2i} - 2) B_{2k-2i} \right) \sigma_{2i+1}(n) \\
&+ \frac{1}{4k+2} \sum_{i=0}^{k-2} \binom{2k+1}{2i+1} \\
&\quad \times \left(\tilde{B}_{2k-2i} - 2^{2k-2i} B_{2k-2i} \right) \tilde{\sigma}_{2i+1}(n).
\end{aligned} \tag{13}$$

Remark 5. The product of two modular forms is another modular form of bigger weight. The dimension $[(k+1)/2]+1$ of space $M_{2k+2}(\Gamma_0(2))$ of modular forms on $\Gamma_0(2)$ is approximately linear for k and the space $E_{2k+2}(\Gamma_0(2))$ generated by generating functions of divisor functions is clearly 2 as k grows. More precisely speaking, for the Eisenstein series G_{2k+2} and G_{2k+2}^* which will be defined in Section 2

$$\begin{aligned}
&G_{2s+2}^*(z) G_{2k-2s}^*(z) \in M_{2k+2}(\Gamma_0(2)) \\
&= E_{2k+2}(\Gamma_0(2)) \bigoplus S_{2k+2}(\Gamma_0(2)),
\end{aligned} \tag{14}$$

where $S_{2k+2}(\Gamma_0(2))$ is the space of cusp form of weight $2k+2$ on $\Gamma_0(2)$ and it is orthogonal complement of $E_{2k+2}(\Gamma_0(2))$ in $M_{2k+2}(\Gamma_0(2))$. Since $E_{2k+2}(\Gamma_0(2)) = \langle G_{2k+2}, G_{2k+2}^* \rangle$ and $S_{2k+2}(\Gamma_0(2)) = \langle h_1, \dots, h_{[(k+1)/2]-1} \rangle$,

$$\begin{aligned} & G_{2s+2}^*(z) G_{2k-2s}^*(z) \\ &= \alpha_1 G_{2k+2}(z) + \alpha_2 G_{2k+2}^*(z) + \sum_{r=1}^{[(k+1)/2]-1} \beta_r h_r(z) \end{aligned} \quad (15)$$

for suitable constants $\alpha_1, \alpha_2, \beta_1, \dots, \beta_{[(k+1)/2]-1}$. On the other hand, Theorems 3 and 4 show that the combinatorial convolution sums are written as only divisor functions; that is,

$$\begin{aligned} & \sum_{s=0}^{k-1} \binom{2k}{2s+1} G_{2s+2}^*(z) G_{2k-2s}^*(z) \\ &= \alpha_1 G_{2k+2}(z) + \alpha_2 G_{2k+2}^*(z). \end{aligned} \quad (16)$$

The disappearance of $\beta_1, \dots, \beta_{[(k+1)/2]-1}$ is observed in Examples 17 and 18.

All calculations in Lemmas 6 and 7 and Theorems 9 and 10 are obtained by usins SAGE.

2. Modular Forms

In this section, we observe the convolution sums as a view point of generating functions of divisor functions.

The normalized Eisenstein series G_k is defined by

$$G_k(z) = -\frac{B_k}{2k} + \sum_{n=1}^{\infty} \sigma_{k-1}(n) q^n. \quad (17)$$

For the generating function of $\sigma_{k-1,1}(n)$ we denote

$$\begin{aligned} G_k^*(z) &:= G_k(z) - 2^{k-1} G_k(2z) \\ &= \frac{2^{k-1}-1}{2k} B_k + \sum_{n=1}^{\infty} \sigma_{k-1,1}(n; 2) q^n. \end{aligned} \quad (18)$$

Let Γ be a finite index subgroup of $\mathrm{SL}(2, \mathbb{Z})$. The *modular form* $f(z)$ of weight k on Γ is a holomorphic function on \mathfrak{H} such that

$$f\left(\frac{az+b}{cz+d}\right) = (cz+d)^k f(z) \quad \forall \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \quad (19)$$

for a positive integer k . The vector space over \mathbb{C} of holomorphic modular forms of weight k on Γ is finite dimensional and is denoted by $M_k(\Gamma)$.

Note that $G_k \in M_k(\mathrm{SL}(2, \mathbb{Z}))$ (if $2 \mid k > 2$) and $G_k^* \in M_k(\Gamma_0(2))$ (if $2 \mid k \geq 2$) for $\Gamma_0(2) = \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2, \mathbb{Z}) : 2 \mid c \}$. Moreover, the product of two modular forms f_1 and f_2 of weights k_1 and k_2 is also modular form of weight $k_1 + k_2$.

The Δ is the discriminant function

$$\Delta(z) = \eta^{24}(z) = \sum_{n \geq 1} \tau(n) q^n \quad (20)$$

with Ramanujan τ -function as its coefficient. It is modular of weight 12 on $\mathrm{SL}(2, \mathbb{Z})$.

Define the following two weight 14 modular forms $\Delta_{14,1}$ and $\Delta_{14,2}$ by using the Dedekind η -function defined in (5):

$$\begin{aligned} \Delta_{14,1}(z) &= 14(G_6^*(z) - 5G_6(z)) \eta^8(z) \eta^8(2z) \\ &= \sum_{N=1}^{\infty} c_{14,1}(N) q^N, \\ \Delta_{14,2}(z) &= 24^3(G_2^*(z))^3 \eta^8(z) \eta^8(2z) = \sum_{N=1}^{\infty} c_{14,2}(N) q^N. \end{aligned} \quad (21)$$

We get the lemma.

Lemma 6. Consider the following:

(1)

$$\begin{aligned} G_2^*(z) G_{10}^*(z) &= \frac{31}{5528} G_{12}(z) - \frac{227}{60808} G_{12}^*(z) \\ &+ \frac{1365}{691} \Delta(z) + \frac{26880}{691} \Delta(2z), \end{aligned} \quad (22)$$

(2)

$$\begin{aligned} G_4^*(z) G_8^*(z) &= \frac{17}{44224} G_{12}(z) - \frac{79}{221120} G_{12}^*(z) \\ &- \frac{203}{691} \Delta(z) - \frac{4928}{691} \Delta(2z), \end{aligned} \quad (23)$$

(3)

$$\begin{aligned} (G_6^*(z))^2 &= \frac{1}{5528} G_{12}(z) - \frac{61}{348264} G_{12}^*(z) \\ &+ \frac{85}{691} \Delta(z) + \frac{2560}{691} \Delta(2z). \end{aligned} \quad (24)$$

Proof. The functions $G_2^* G_{10}^*$, $G_4^* G_8^*$, and $(G_6^*)^2$ are modular functions of weight 12 on $\Gamma_0(2)$. Note that $M_{12}(\Gamma_0(2))$ is a 4-dimensional vector space over \mathbb{C} generated by $G_{12}(z)$, $G_{12}^*(z)$, $\Delta(z)$, and $\Delta(2z)$ because $\dim_{\mathbb{C}}(M_k(\Gamma_0(2))) = [k/4] + 1$. Their q -expansions are as follows:

$$\begin{aligned} G_{12}(z) &= \frac{691}{65520} + q + 2049q^2 + 177148q^3 \\ &+ 4196353q^4 + 48828126q^5 + O(q^6), \end{aligned}$$

$$\begin{aligned} G_{12}^*(z) &= -\frac{1414477}{65520} + q + q^2 + 177148q^3 + q^4 \\ &+ 48828126q^5 + O(q^6), \end{aligned}$$

$$\begin{aligned} \Delta(z) &= q - 24q^2 + 252q^3 - 1472q^4 \\ &+ 4830q^5 + O(q^6), \end{aligned}$$

$$\begin{aligned} G_2^*(z) G_{10}^*(z) &= \frac{511}{6336} + \frac{87}{44}q + \frac{131}{44}q^2 + \frac{9129}{11}q^3 \\ &+ \frac{866403}{44}q^4 + \frac{2223801}{22}q^5 + O(q^6), \end{aligned}$$

$$\begin{aligned}
G_4^*(z)G_8^*(z) &= \frac{889}{115200} - \frac{47}{160}q + \frac{113}{160}q^2 - \frac{2769}{40}q^3 \\
&\quad + \frac{354673}{160}q^4 - \frac{7521}{80}q^5 + O(q^6), \\
(G_6^*(z))^2 &= \frac{961}{254016} + \frac{31}{252}q + \frac{283}{252}q^2 + \frac{2017}{63}q^3 \\
&\quad + \frac{123259}{252}q^4 + \frac{36731}{42}q^5 + O(q^6).
\end{aligned} \tag{25}$$

By comparing the above expansions with ones of $G_{2s}^*(z)$ for $s = 1, 2, 3$, we get our result. \square

Lemma 7. Consider the following:

(1)

$$\begin{aligned}
G_2^*(z)G_{12}^*(z) &= \frac{691}{174752}G_{14}(z) - \frac{1885739}{715609440}G_{14}^*(z) \\
&\quad - \frac{891}{86}\Delta_{14,1}(z) - \frac{8525}{762}\Delta_{14,2}(z),
\end{aligned} \tag{26}$$

(2)

$$\begin{aligned}
G_4^*(z)G_{10}^*(z) &= \frac{31}{174752}G_{14}(z) - \frac{4769}{28834080}G_{14}^*(z) \\
&\quad + \frac{81}{86}\Delta_{14,1}(z) + \frac{245}{254}\Delta_{14,2}(z),
\end{aligned} \tag{27}$$

(3)

$$\begin{aligned}
G_6^*(z)G_8^*(z) &= \frac{17}{349504}G_{14}(z) - \frac{5249}{110093760}G_{14}^*(z) \\
&\quad - \frac{9}{86}\Delta_{14,1}(z) - \frac{25}{254}\Delta_{14,2}(z).
\end{aligned} \tag{28}$$

Proof. One can prove these by using a similar way to Lemma 6 and 4-dimensional vector space $M_{14}(\Gamma_0(2))$ generated by G_{14} , G_{14}^* , $\Delta_{14,1}$, and $\Delta_{14,2}$ over \mathbb{C} because their q -expansions are as follows:

$$\begin{aligned}
G_{14}(z) &= -\frac{1}{24} + q + 8193q^2 + 1594324q^3 \\
&\quad + 67117057q^4 + 1220703126q^5 + O(q^6), \\
G_{14}^*(z) &= \frac{8191}{24} + q + q^2 + 1594324q^3 \\
&\quad + q^4 + 1220703126q^5 + O(q^6),
\end{aligned} \tag{29}$$

$$\begin{aligned}
\Delta_{14,1}(z) &= q - 64q^2 - 1836q^3 \\
&\quad + 4096q^4 + 3990q^5 + O(q^6),
\end{aligned}$$

$$\begin{aligned}
\Delta_{14,2}(z) &= q + 64q^2 + 1236q^3 \\
&\quad + 4096q^4 - 57450q^5 + O(q^6).
\end{aligned}$$

Remark 8. (1) $\Delta(z)$ is the normalized Hecke eigenform on the full modular group of weight 12:

$$\begin{aligned}
\tau(p^{r+1}) &= \tau(p^r)\tau(p) - p^{11}\tau(p^{r-1}) \quad \text{for } p \text{ prime, } r \geq 1, \\
\tau(mn) &= \tau(m)\tau(n) \quad \text{if } \gcd(m, n) = 1.
\end{aligned} \tag{30}$$

(2) $\Delta_{14,1}(z)$ and $\Delta_{14,2}(z)$ are normalized newforms on $\Gamma_0(2)$ of weight 14. The coefficients $c_{k,j}(n)$ ($j = 1, 2$) satisfy that

$$\begin{aligned}
c_{14,j}(p^{r+1}) &= c_{14,j}(p^r)c_{14,j}(p) \\
&\quad - p^{13}c_{14,j}(p^{r-1}) \quad \text{for } p \text{ odd prime } p, r \geq 1, \\
c_{14,j}(2^r) &= c_{14,j}(2)^r \quad \text{for } r \geq 0, \\
c_{14,j}(mn) &= c_{14,j}(m)c_{14,j}(n) \quad \text{if } \gcd(m, n) = 1.
\end{aligned} \tag{31}$$

Moreover, for the Atkin-Lehner involution $W_2 = \begin{pmatrix} 0 & -1 \\ 2 & 1 \end{pmatrix}$,

$$\Delta_{14,1}|_{14}W_2 = \Delta_{14,1}, \quad \Delta_{14,2}|_{14}W_2 = -\Delta_{14,2} \tag{32}$$

if we define the action $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{GL}(2, \mathbb{Q})$ on the complex valued function f as

$$(f|_k\gamma)(z) = \det(\gamma)^{k/2}(cz+d)^{-k}f\left(\frac{az+b}{cz+d}\right). \tag{33}$$

By the help of Lemmas 6 and 7 we get the formulae for each convolution sum.

Theorem 9. Consider the following:

(1)

$$\begin{aligned}
\sum_{m=1}^{n-1} \sigma_{1,1}(m; 2)\sigma_{9,1}(n-m; 2) \\
&= \frac{31}{5528}\sigma_{11}(n) - \frac{227}{60808}\sigma_{11,1}(n; 2) - \frac{1}{24}\sigma_{9,1}(n; 2) \\
&\quad - \frac{511}{264}\sigma_{1,1}(n; 2) + \frac{1365}{691}\tau(n) + \frac{26880}{691}\tau\left(\frac{n}{2}\right),
\end{aligned} \tag{34}$$

(2)

$$\begin{aligned}
\sum_{m=1}^{n-1} \sigma_{3,1}(m; 2)\sigma_{7,1}(n-m; 2) \\
&= \frac{17}{44224}\sigma_{11}(n) - \frac{79}{221120}\sigma_{11,1}(n; 2) + \frac{7}{240}\sigma_{7,1}(n; 2) \\
&\quad + \frac{127}{480}\sigma_{3,1}(n; 2) - \frac{203}{691}\tau(n) - \frac{4928}{691}\tau\left(\frac{n}{2}\right),
\end{aligned} \tag{35}$$

$$\begin{aligned}
(3) \quad & \sum_{m=1}^{n-1} \sigma_{5,1}(m; 2) \sigma_{5,1}(n-m; 2) \\
& = \frac{1}{5528} \sigma_{11}(n) - \frac{61}{348264} \sigma_{11,1}(n; 2) \\
& \quad - \frac{31}{252} \sigma_{5,1}(n; 2) + \frac{85}{691} \tau(n) + \frac{2560}{691} \tau\left(\frac{n}{2}\right). \tag{36}
\end{aligned}$$

Theorem 10. Consider the following:

(1)

$$\begin{aligned}
& \sum_{m=1}^{n-1} \sigma_{1,1}(m; 2) \sigma_{11,1}(n-m; 2) \\
& = \frac{691}{174752} \sigma_{13}(n) - \frac{1885739}{715609440} \sigma_{13,1}(n; 2) - \frac{1}{24} \sigma_{11,1}(n; 2) \\
& \quad + \frac{1414477}{65520} \sigma_{1,1}(n; 2) - \frac{891}{86} c_{14,1}(n) - \frac{8625}{762} c_{14,2}(n), \tag{37}
\end{aligned}$$

(2)

$$\begin{aligned}
& \sum_{m=1}^{n-1} \sigma_{3,1}(m; 2) \sigma_{9,1}(n-m; 2) \\
& = \frac{31}{174752} \sigma_{13}(n) - \frac{4769}{28834080} \sigma_{13,1}(n; 2) + \frac{7}{240} \sigma_{9,1} \\
& \quad \times (n; 2) - \frac{511}{264} \sigma_{3,1}(n; 2) - \frac{81}{86} c_{14,1}(n) + \frac{245}{254} c_{14,2}(n), \tag{38}
\end{aligned}$$

(3)

$$\begin{aligned}
& \sum_{m=1}^{n-1} \sigma_{5,1}(m; 2) \sigma_{7,1}(n-m; 2) \\
& = \frac{17}{349504} \sigma_{13}(n) - \frac{5249}{110093760} \sigma_{13,1}(n; 2) - \frac{31}{504} \sigma_{7,1}(n; 2) \\
& \quad + \frac{127}{480} \sigma_{5,1}(n; 2) - \frac{9}{86} c_{14,1}(n) - \frac{25}{254} c_{14,2}(n). \tag{39}
\end{aligned}$$

3. Proof of Theorems

In his series of eighteen papers published between 1858 and 1865, Joseph Liouville (1809–1882) stated without proof several elementary arithmetic formulae. One of these is the following formula.

Proposition 11 (see [10, page 112]). Let $f: \mathbb{Z} \rightarrow \mathbb{C}$ be an even function. Let $n \in \mathbb{N}$. Then one obtains

$$\sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} (f(a-b) - f(a+b))$$

$$\begin{aligned}
& = f(0) (\sigma_1^*(n) - \sigma_0^*(n)) - \frac{1}{2} \sum_{\substack{d \in \mathbb{N} \\ d|n \\ d \text{ even}}} df(d) \\
& \quad - 2 \sum_{\substack{d \in \mathbb{N} \\ d|n \\ d \text{ odd}}} \sum_{\substack{t \in \mathbb{N} \\ 1 \leq t < d \\ t \text{ even}}} f(t). \tag{40}
\end{aligned}$$

Now we are ready to prove our theorems in Section 1.

Proof of Theorem 3. We apply $f(x) = x^{2k}$ ($k \geq 1$) in Proposition 11. Then the left-hand side is

$$\begin{aligned}
& \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} (a-b)^{2k} - (a+b)^{2k} \\
& = \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} \left(\sum_{r=0}^{2k} \binom{2k}{r} (-1)^r a^{2k-r} b^r \right. \\
& \quad \left. - \sum_{r=0}^{2k} \binom{2k}{r} a^{2k-r} b^r \right) \\
& = -2 \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} \sum_{r=0}^{2k} \binom{2k}{r} a^{2k-r} b^r \\
& = -2 \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} a^{2k-2s-1} b^{2s+1} \\
& = -2 \sum_{s=0}^{k-1} \binom{2k}{2s+1} \\
& \quad \times \sum_{m=1}^{n-1} \left(\sum_{\substack{a|m \\ 2 \nmid a}} a^{2k-2s-1} \right) \left(\sum_{\substack{b|(n-m) \\ 2 \nmid b}} b^{2s+1} \right) \\
& = -2 \sum_{m=1}^{n-1} \sum_{s=0}^{k-1} \binom{2k}{2s+1} \\
& \quad \times \sigma_{2k-2s-1,1(m;2)} \sigma_{2s+1,1(n-m;2)}. \tag{41}
\end{aligned}$$

On the other hand by using Bernoulli's identity [10, page 42],

$$\sum_{l=1}^{n-1} l^k = \frac{1}{k+1} \sum_{j=0}^k \binom{k+1}{j} B_j n^{k+1-j}, \tag{42}$$

the right-hand side is

$$\begin{aligned}
& \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} (a-b)^{2k} - (a+b)^{2k} \\
&= \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} \left(\sum_{r=0}^{2k} \binom{2k}{r} (-1)^r a^{2k-r} b^r \right. \\
&\quad \left. - \sum_{r=0}^{2k} \binom{2k}{r} a^{2k-r} b^r \right) \\
&= -2 \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} \sum_{\substack{r=0 \\ r \text{ odd}}}^{2k} \binom{2k}{r} a^{2k-r} b^r \\
&= -2 \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{\substack{(a,b,x,y) \in \mathbb{N}^4 \\ ax+by = n \\ a,b \text{ odd}}} a^{2k-2s-1} b^{2s+1} \\
&= -2 \sum_{s=0}^{k-1} \binom{2k}{2s+1} \\
&\quad \times \sum_{m=1}^{n-1} \left(\sum_{\substack{a|m \\ 2 \nmid a}} a^{2k-2s-1} \right) \left(\sum_{\substack{b|(n-m) \\ 2 \nmid b}} b^{2s+1} \right) \\
&= -2 \sum_{m=1}^{n-1} \sum_{s=0}^{k-1} \binom{2k}{2s+1} \\
&\quad \times \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(n-m; 2). \tag{43}
\end{aligned}$$

After dividing both sides by -2 we get

$$2^{2k-1} \sigma_{2k+1} \left(\frac{n}{2} \right) + \frac{1}{4k+2} \sum_{i=0}^k \tilde{B}_{2k-2i} \binom{2k+1}{2i+1} \sigma_{2i+1,1}(n; 2). \tag{44}$$

□

Remark 12. When f is a constant function in Proposition 11, it is a trivial formula such that

$$\sigma_1(n) = 2\sigma_1^*(n) - \sigma_{1,1}(n; 2). \tag{45}$$

Corollary 13. For $k \geq 1$,

$$\sum_{r=0}^{2k+1} \sum_{j=0}^{2k+1-r} \binom{2k+1}{j, r, 2k+1-r-j} 2^j B_j = 0. \tag{46}$$

Proof. Applying $n = 1$ in Theorem 3, our result is proved. □

Corollary 14. Let $N \in \mathbb{N}$. Then one has

$$\begin{aligned}
& \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{\substack{m=1 \\ 2 \nmid m}}^{2N} \sigma_{2k-2s-1}(m) \sigma_{2s+1}(2N-m) \\
&= 2^{2k-1} \sigma_{2k+1}^*(N). \\
\text{Proof. } & \text{Let } n = 2N \text{ in Theorem 3. Then the left-hand side is} \\
& \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{2N-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(2N-m; 2) \\
&= \sum_{s=0}^{k-1} \binom{2k}{2s+1} \\
&\quad \times \left[\sum_{\substack{m=1 \\ 2 \mid m}}^{2N-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(2N-m; 2) \right. \\
&\quad \left. + \sum_{\substack{m=1 \\ 2 \nmid m}}^{2N-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(2N-m; 2) \right] \\
&= \sum_{s=0}^{k-1} \binom{2k}{2s+1} \\
&\quad \times \left[\sum_{m=1}^{N-1} \sigma_{2k-2s-1,1}(2m; 2) \sigma_{2s+1,2}(2N-2m) \right. \\
&\quad \left. + \sum_{\substack{m=1 \\ 2 \mid m}}^{2N-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(2N-m; 2) \right]
\end{aligned} \tag{47}$$

$$\begin{aligned}
&= \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{N-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(N-m; 2) \\
&\quad + \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{\substack{m=1 \\ 2 \mid m}}^{2N-1} \sigma_{2k-2s-1}(m) \sigma_{2s+1}(2N-m).
\end{aligned} \tag{48}$$

The right-hand side of Theorem 3 for $n = 2N$ is

$$\begin{aligned}
& 2^{2k-1} \sigma_{2k+1}(N) + \frac{1}{4k+2} \sum_{i=0}^k \binom{2k+1}{2i+1} \tilde{B}_{2k-2i} \sigma_{2i+1,1}(2N; 1) \\
&= 2^{2k-1} \sigma_{2k+1}(N) + \frac{1}{4k+2} \\
&\quad \times \sum_{i=0}^k \binom{2k+1}{2i+1} \tilde{B}_{2k-2i} \sigma_{2i+1,1}(N; 2)
\end{aligned}$$

$$\begin{aligned}
&= 2^{2k-1} \sigma_{2k+1}(N) - 2^{2k-1} \sigma_{2k+1}\left(\frac{N}{2}\right) \\
&\quad + \sum_{i=0}^{k-1} \binom{2k}{2i+1} \sum_{m=1}^{N-1} \sigma_{2k-2i-1,1}(m; 2) \sigma_{2i+1,1}(N-m; 2). \tag{49}
\end{aligned}$$

Since $\sigma_s^*(N) = \sigma_s(N) - \sigma_s(N/2)$, we are done. \square

Remark 15. The above result is also in [8, Theorem 3.4], but we do not use the combinatoric convolution sums of σ_k^* -functions but odd divisor function.

Corollary 16. For the odd prime p case, one has

$$\begin{aligned}
&\sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{p-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(p-m; 2) \\
&= \frac{1}{4k+2} \sum_{r=0}^{2k+1} \sum_{j=0}^{2k+1-r} \binom{2k+1}{j, r, 2k+1-j-r} 2^j p^r B_j. \tag{50}
\end{aligned}$$

Proof. In Theorem 3,

$$\begin{aligned}
&\sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{p-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(p-m; 2) \\
&= \frac{1}{4k+2} \sum_{s=0}^k \tilde{B}_{2k-2s} \binom{2k+1}{2s+1} \sigma_{2s+1,1}(p; 2) \\
&= \frac{1}{4k+2} \sum_{r=0}^{2k+1} \tilde{B}_{2k-r+1} \binom{2k+1}{r} \sigma_r(p) \\
&= \frac{1}{4k+2} \sum_{r=0}^{2k+1} \sum_{j=0}^{2k+1-r} \binom{2k+1}{j, r, 2k+1-j-r} 2^j B_j (1+p^r) \\
&= \frac{1}{4k+2} \sum_{r=0}^{2k+1} \sum_{j=0}^{2k+1-r} \binom{2k+1}{j, r, 2k+1-j-r} 2^j p^r B_j \tag{51}
\end{aligned}$$

by Corollary 13. \square

Proof of Theorem 4. Note that

$$\begin{aligned}
\tilde{\sigma}_s(n) &= \sigma_s(n) - 2^{s+1} \sigma_s\left(\frac{n}{2}\right), \\
\sigma_{s,1}(n; 2) &= \sigma_s(n) - 2^s \sigma_s\left(\frac{n}{2}\right). \tag{52}
\end{aligned}$$

We reconsider Proposition 1 as the last one in the previous line:

$$\begin{aligned}
&\sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \sigma_{2k-2s-1}\left(\frac{m}{2}\right) \sigma_{2s+1}\left(\frac{n-m}{2}\right) \\
&= \frac{2k+3}{4k+2} \sigma_{2k+1}\left(\frac{n}{2}\right) + \left(\frac{k}{6} - \frac{n}{2}\right) \sigma_{2k-1}\left(\frac{n}{2}\right) \tag{53} \\
&\quad + \frac{1}{2k+1} \sum_{j=2}^k \binom{2k+1}{2j} B_{2j} \sigma_{2k+1-2j}\left(\frac{n}{2}\right).
\end{aligned}$$

Thus,

$$\begin{aligned}
&\sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \tilde{\sigma}_{2k-2s-1}(m) \tilde{\sigma}_{2s+1}(n-m) \\
&= \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \left(\sigma_{2k-2s-1}(m) - 2^{2k-2s} \sigma_{2k-2s-1}\left(\frac{m}{2}\right) \right) \\
&\quad \times \left(\sigma_{2s+1}(n-m) - 2^{2s+2} \sigma_{2s+1}\left(\frac{n-m}{2}\right) \right) \\
&= 2 \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \sigma_{2k-2s-1,1}(m; 2) \sigma_{2s+1,1}(n-m; 2) \\
&\quad - \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \sigma_{2k-2s-1}(m) \sigma_{2s+1}(n-m) \\
&\quad + 2^{2k+1} \sum_{s=0}^{k-1} \binom{2k}{2s+1} \sum_{m=1}^{n-1} \sigma_{2k-2s-1}\left(\frac{m}{2}\right) \sigma_{2s+1}\left(\frac{n-m}{2}\right) \\
&= -\frac{1}{2} \tilde{\sigma}_{2k+1}(n) + \left(n - \frac{k}{2}\right) \tilde{\sigma}_{2k-1}(n) + \frac{1}{4k+2} \\
&\quad \times \sum_{i=0}^{k-2} \binom{2k+1}{2i+1} (\tilde{B}_{2k-2i} + (2^{2k-2i} - 2) B_{2k-2i}) \sigma_{2s+1}(n) \\
&\quad + \frac{1}{4k+2} \sum_{i=0}^{k-2} \binom{2k+1}{2i+1} (\tilde{B}_{2k-2i} - 2^{2k-2i} B_{2k-2i}) \tilde{\sigma}_{2i+1}(n) \tag{54}
\end{aligned}$$

by Proposition 1, Theorem 3, and (53). \square

The following examples show us that the coefficients of cusp forms disappear in the combinatorial convolution sum for the weights 12 and 14, explicitly.

Example 17. Consider the case of Theorem 3 for $k = 5$. The left-hand side is

$$\begin{aligned}
&\sum_{s=0}^4 \binom{10}{2s+1} \sum_{m=1}^{n-1} \sigma_{9-2s,1}(m; 2) \sigma_{2s+1}(n-m; 2) \\
&= 20 \sum_{m=1}^{n-1} \sigma_{1,1}(m; 2) \sigma_{1,1}(n-m; 2) \\
&\quad + 240 \sum_{m=1}^{n-1} \sigma_{3,1}(m; 2) \sigma_{7,1}(n-m; 2) \\
&\quad + 252 \sum_{m=1}^{n-1} \sigma_{5,1}(m; 2) \sigma_{5,1}(n-m; 2). \tag{55}
\end{aligned}$$

When we put the formula in Theorem 9 in the above, the coefficients of $\tau(n)$ and $\tau(n/2)$ are zero.

Example 18. The left-hand side of Theorem 3 when $k = 6$ is

$$\begin{aligned} & 24 \sum_{m=1}^{n-1} \sigma_{1,1}(m; 2) \sigma_{11,1}(n-m; 2) \\ & + 440 \sum_{m=1}^{n-1} \sigma_{3,1}(m; 2) \sigma_{9,1}(n-m; 2) \\ & + 1584 \sum_{m=1}^{n-1} \sigma_{5,1}(m; 2) \sigma_{7,1}(n-m; 2). \end{aligned} \quad (56)$$

By applying Theorem 10 to the above, one can check that our theorem is true and the coefficients $c_{14,1}(n)$ and $c_{14,2}(n)$ of cusp forms disappear.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
