Intermittency and infinite variance: the case of integrated supOU processes* 

Danijel Grahovac†  Nikolai N. Leonenko‡  Murad S. Taqqu§

Abstract

SupOU processes are superpositions of Ornstein-Uhlenbeck type processes with a random intensity parameter. They are stationary processes whose marginal distribution and dependence structure can be specified independently. Integrated supOU processes have then stationary increments and satisfy central and non-central limit theorems. Their moments, however, can display an unusual behavior known as “intermittency”. We show here that intermittency can also appear when the processes have a heavy tailed marginal distribution and, in particular, an infinite variance.

Keywords: supOU processes; Ornstein-Uhlenbeck process; absolute moments; limit theorems; infinite variance.

MSC2020 subject classifications: 60F05; 60G52; 60G10.

Submitted to EJP on October 22, 2019, final version accepted on April 3, 2021.

1 Introduction

Superpositions of Ornstein-Uhlenbeck type (supOU) processes provide models with analytically and stochastically tractable dependence structure displaying either weak or strong dependence and also having marginal distributions that are infinitely divisible. They have applications in environmental studies, ecology, meteorology, geophysics, biology, see [4, 5, 29] and the references therein. The supOU processes are particularly relevant in finance and the statistical theory of turbulence since they can model key stylized features of observational series from finance and turbulence (see e.g. [5, 9, 10, 12, 13, 6, 33]). Recently in [23], the supOU processes have even been used to assess the mass of black hole.

Intermittency and infinite variance

SupOU processes form a rich class of stationary processes with a flexible dependence structure. They are defined as integrals with respect to an infinitely divisible random measure (see Section 2) and their distribution is determined by the characteristic quadruple

\[(a, b, \mu, \pi), \quad (1.1)\]

where \((a, b, \mu)\) is some Lévy-Khintchine triplet (see e.g. [31]) and \(\pi\) is a probability measure on \(R_+\). In the construction of the supOU process \(\{X(t), t \in R\}\), the choice of \((a, b, \mu)\) uniquely characterizes the one-dimensional marginals. These do not depend on the choice of \(\pi\). The probability distribution \(\pi\) affects the dependence structure however. See Section 2 and [2, 5, 11, 12, 13, 17] for details.

By aggregating the supOU process \(\{X(t), t \in R\}\) one obtains the integrated supOU process

\[X^*(t) = \int_0^t X(s)ds. \quad (1.2)\]

A suitably normalized integrated process exhibits complex limiting behavior. Indeed, if the underlying supOU process has finite variance, then four classes of processes may arise in a classical limiting scheme ([19]). Namely, the limit process may be Brownian motion, fractional Brownian motion, a stable Lévy process or a stable process with dependent increments. The type of limit depends on whether the Gaussian component is present in (1.1) or not, on the behavior of \(\pi\) in (1.1) near the origin and on the growth of the Lévy measure \(\mu\) in (1.1) near the origin (see [19] for details). In the infinite variance case, the limiting behavior is even more complex as the limit process may additionally depend on the regular variation index of the marginal distribution (see [20] for details).

The limiting behavior of the integrated process has practical significance since supOU processes may be used as stochastic volatility models, see [1, 10] and the references therein. In this setting the integrated process \(X^*\) represents the integrated volatility (see e.g. [12]). Moreover, the limiting behavior is important for statistical estimation (see [27, 32]).

The integrated supOU process may exhibit another interesting limiting property related to behavior of their absolute moments in time. Although a suitably normalized integrated process satisfies a limit theorem, it may happen that its moments do not converge beyond some critical order. One way to investigate this behavior is to measure the rate of growth of moments by the scaling function, defined for a generic process \(Y = \{Y(t), t \geq 0\}\) as

\[\tau_Y(q) = \lim_{t \to \infty} \frac{\log E|Y(t)|^q}{\log t}, \quad (1.3)\]

assuming the limit in (1.3) exists and is finite. We will often focus on

\[\frac{\tau_Y(q)}{q} = \lim_{t \to \infty} \frac{\log (E|Y(t)|^q)^{1/q}}{\log t}\]

which has the advantage of involving \((E|Y(t)|^q)^{1/q}\) which has the same units as \(Y(t)\). The values \(q\) are assumed to be in the range of finite moments \(q \in (0, \eta(Y))\), where

\[\eta(Y) = \sup\{q > 0 : E|Y(t)|^q < \infty \forall t\}.\]

To see how this is related to limit theorems, suppose that \(Y\) satisfies a limit theorem in the form

\[\left\{ \frac{Y(Tt)}{A_T} \right\} \overset{d}{\to} \{Z(t)\},\]

with \(A_T\) a sequence of constants and convergence in the sense of convergence of all finite-dimensional distributions as \(T \to \infty\). By Lamperti’s theorem (see, for example, [28,
Intermittency and infinite variance

Theorem 2.8.5), the limit $Z$ is $H$-self-similar for some $H > 0$, that is, for any constant $c > 0$, the finite-dimensional distributions of $Z(ct)$ are the same as those of $c^H Z(t)$. Moreover, the normalizing sequence is of the form $A_T = \ell(T)^{-H}$ for some $\ell$ slowly varying at infinity. For self-similar process, the moments evolve as a power function of time since $E|Z(t)|^q = E|Z(1)|^q t^{Hq}$ and therefore the scaling function of $Z$ is $\tau_Z(q) = Hq$. If for some $q > 0$ we have

$$\frac{E|Y(T)|^q}{A_T^q} \to E|Z(t)|^q, \quad \forall t \geq 0,$$

then the scaling function of $Y$ would also be $\tau_Y(q) = Hq$ (see [17, Theorem 1]), and the function

$$q \mapsto \frac{\tau_Y(q)}{q} = \frac{Hq}{q} = H$$

would be constant over values of $q$ for which (1.4) holds.

It was shown in [17] that the integrated supOU process $X^*$ may have the scaling function

$$\tau_{X^*}(q) = q - \alpha$$

for a certain range of $q$. Thus its scaling function is different from that of a self-similar process. This situation happens, for example, for a non-Gaussian integrated supOU process with marginal distribution having exponentially decaying tails and probability measure $\pi$ in (1.1) regularly varying at zero.

Note that the relation (1.6) implies that the function

$$q \mapsto \frac{\tau_{X^*}(q)}{q} = \frac{q - \alpha}{q} = 1 - \frac{\alpha}{q}$$

is not constant. It has points of strict increase, a property referred to as intermittency. This term is used in all kind of different contexts. It refers in general to an unusual moment behavior and is used in various applications such as turbulence, magnetohydrodynamics, rain and cloud studies, physics of fusion plasmas (see e.g. [16, Chapter 8] or [36]).

Hence, intermittency implies that the usual convergence of moments (1.4) must not hold beyond some critical value of $q$. The papers [17, 18, 19] provide a complete picture on the behavior of moments in the case where $X(t)$ has finite variance.

We focus here on the limiting behavior of moments and on the intermittency in the case where $X(t)$ has infinite variance and show that we can have intermittency even in this case. To establish the rate of growth of moments we make use of the limit theorems established in [20]. The type of the limiting process depends heavily on the structure of the underlying supOU process. Hence, the form of the scaling function of the integrated process will depend on the several parameters related to the quadruple (1.1). Special care is needed since the range of finite moments is limited. We show that the scaling function may look like a broken line indicating that there is a change-point in the rate of growth of moments. Hence, infinite variance integrated supOU processes may also exhibit the phenomenon of intermittency. Our results also indicate that in some cases, if we decompose the process into several components, the intermittency of the finite variance component may remain hidden by the infinite moments of the infinite variance component. We conclude that moments may have limited capability in identifying unusual limiting behavior.

The paper is organized as follows. In Section 2 we introduce notation and assumptions. Section 3 contains the main results and all the proofs are given in Section 4.
Intermittency and infinite variance

2 Preliminaries and assumptions

We shall use the notation
\[ \kappa_Y(\zeta) = C \{ \zeta \downarrow Y \} = \log \mathbb{E} e^{i\zeta Y}, \quad \zeta \in \mathbb{R}, \]
to denote the cumulant (generating) function of a random variable \( Y \). For a stochastic process \( Y = \{ Y(t) \} \) we write \( \kappa_Y(\zeta, t) = \kappa_Y(t)(\zeta) \), and by suppressing \( t \) we mean \( \kappa_Y(\zeta) = \kappa_Y(\zeta, 1) \), that is the cumulant function of the random variable \( Y(1) \).

2.1 SupOU processes

The class of supOU processes has been introduced by Barndorff-Nielsen in [2] as follows. Let \( m \) be the product \( m = \pi \times \text{Leb} \) of a probability measure \( \pi \) on \( \mathbb{R}_+ \) and the Lebesgue measure on \( \mathbb{R} \). A homogeneous infinitely divisible random measure (Lévy basis) on \( \mathbb{R}_+ \times \mathbb{R} \) with control measure \( m \) is a random measure such that the cumulant function of the random variable \( \Lambda(A) \), where \( A \in \mathcal{B}(\mathbb{R}_+ \times \mathbb{R}) \) has finite measure, equals
\[ C \{ \zeta \downarrow \Lambda(A) \} = m(A) \kappa_L(\zeta) = (\pi \times \text{Leb})(A) \kappa_L(\zeta). \]
Here \( \kappa_L \) is the cumulant function \( \kappa_L(\zeta) = \log \mathbb{E} e^{i\zeta L(1)} \) of some infinitely divisible random variable \( L(1) \) with Lévy-Khintchine triplet \( (a, b, \mu) \) i.e.
\[ \kappa_L(\zeta) = i\zeta a - \frac{\zeta^2}{2} b + \int_{\mathbb{R}} (e^{i\zeta x} - 1 - i\zeta x1_{[-1,1]}(x)) \mu(dx). \quad (2.1) \]
The Lévy process \( L = \{ L(t), t \geq 0 \} \) associated with the triplet \( (a, b, \mu) \) is called the background driving Lévy process (see [10]). It has independent stationary increments and thus, its finite-dimensional distributions depend only on the distribution of \( L(1) \).

The supOU process is a strictly stationary process \( X = \{ X(t), t \in \mathbb{R} \} \) given by the stochastic integral \((2.2)\)
\[ X(t) = \int_{s=-\infty}^{\infty} \int_{\xi=0}^{\infty} e^{-\xi t + s} 1_{[0,\infty)}(\xi t - s) \Lambda(d\xi, ds). \quad (2.2) \]
By appropriately choosing the infinitely divisible distribution \( L(1) \), one can obtain any self-decomposable distribution as a marginal distribution of \( X \). Note that the one-dimensional marginals of the supOU process are independent on the choice of \( \pi \). The probability measure \( \pi \) “randomizes” the rate parameter \( \xi \) in \( (2.2) \) and the Lebesgue measure \( ds \) is associated with the moving average variable \( s \). The quadruple \( (a, b, \mu, \pi) \) given in \((1.1)\) determines the law of the supOU process \( \{ X(t), t \in \mathbb{R} \} \). More details about supOU processes can be found in [2, 5, 7, 8, 11, 17].

We will consider below supOU processes with marginal distributions in the domain of attraction of stable law. Recall that a stable distribution \( S_\gamma(\sigma, \rho, c) \) with parameters \( 0 < \gamma < 2, \sigma > 0, -1 \leq \rho \leq 1 \) and \( c \in \mathbb{R} \), has a cumulant function of the form:
\[ \kappa_{S_\gamma(\sigma, \rho, c)}(\zeta) := C \{ \zeta \downarrow Z \} = i\zeta - \sigma \gamma |\zeta|^\gamma (1 - i\rho \text{sign}(\zeta) \chi(\zeta, \gamma)), \quad \zeta \in \mathbb{R}, \quad (2.3) \]
where
\[ \chi(\zeta, \gamma) = \begin{cases} \tan \left( \frac{\pi \gamma}{2} \right), & \gamma \neq 1, \\ \frac{\pi}{2} \log |\zeta|, & \gamma = 1. \end{cases} \]
When \( \gamma \neq 1 \), then \( S_\gamma(\sigma, \rho, c) \) is strictly stable if and only if \( c = 0 \). For \( \gamma = 1 \), \( S_1(\sigma, \rho, c) \) is strictly stable if and only if \( \rho = 0 \).
2.2 Basic assumptions

We now state a set of assumptions for the class of supOU processes we consider.

**Assumption 2.1.** The supOU process \( \{X(t), t \in \mathbb{R}\} \) is such that the following holds:

(i) The marginal distribution satisfies

\[
P(X(1) > x) \sim pk(x)x^{-\gamma} \quad \text{and} \quad P(X(1) \leq -x) \sim qk(x)x^{-\gamma}, \quad \text{as } x \to \infty,
\]

for some \( p, q \geq 0, p + q > 0, 0 < \gamma < 2 \) and some slowly varying function \( k \). If \( \gamma = 1 \), we assume \( p = q \). When the mean is finite, we assume \( \mathbb{E}X(1) = 0 \).

(ii) \( \pi \) has a density \( p \) satisfying

\[
p(x) \sim \alpha \ell(x^{-1})x^{\alpha-1}, \quad \text{as } x \to 0,
\]

for some \( \alpha > 0 \) and some slowly varying function \( \ell \) and

\[
\int_0^\infty \xi \pi(d\xi) < \infty.
\]

(iii) The behavior at the origin of the Lévy measure \( \mu \) is given by

\[
\mu([x, \infty)) \sim c^+ x^{-\beta} \quad \text{and} \quad \mu((-\infty, -x]) \sim c^- x^{-\beta} \quad \text{as } x \to 0,
\]

for some \( 0 \leq \beta < 2, \beta \neq 1 + \alpha, c^+, c^- \geq 0, c^+ + c^- > 0 \).

Assumption 2.1(i) implies that the marginal distribution is in the domain of attraction of an infinite variance stable law \( S_{\gamma}(\sigma, \rho, 0) \) with (see [22, Theorem 2.6.1])

\[
\sigma = \left( \frac{\Gamma(2 - \gamma)}{1 - \gamma} (p + q) \cos \left( \frac{\pi \gamma}{2} \right) \right)^{1/\gamma}, \quad \rho = \frac{p - q}{p + q}.
\]

Note that this is a strictly stable law since \( \rho = 0 \) if \( \gamma = 1 \). By [15, Proposition 3.1], the tail of the distribution function of \( X(1) \) is asymptotically equivalent to the tail of the background driving Lévy process \( L(t) \) at \( t = 1 \). More precisely, as \( x \to \infty \)

\[
P(L(1) > x) \sim \gamma P(X(1) > x) \quad \text{and} \quad P(L(1) \leq -x) \sim \gamma P(X(1) \leq -x).
\]

Hence, (2.4) implies

\[
P(L(1) > x) \sim p\gamma k(x)x^{-\gamma} \quad \text{and} \quad P(L(1) \leq -x) \sim q\gamma k(x)x^{-\gamma}, \quad \text{as } x \to \infty,
\]

and \( L(1) \) is in the domain of attraction of stable distribution \( S_{\gamma}(\gamma^{1/\gamma} \sigma, \rho, 0) \).

The next assumption, Assumption 2.1(ii), concerns the dependence structure controlled by the behavior near the origin of the probability measure \( \pi \) in the characteristic quadruple (1.1). In the finite variance case, \( \pi \) is directly related to the correlation function of the supOU process \( X \):

\[
r(t) = \int_{\mathbb{R}_+} e^{-\xi t} \pi(d\xi), \quad t \geq 0.
\]

Hence, by a Tauberian argument, the decay of the correlation function at infinity is related to the decay of the distribution function of \( \pi \) at zero (see [15, Proposition 2.6]). We assume \( \pi \) has a density for simplicity. Note that if the variance of the supOU process is finite and \( \alpha \in (0,1) \), then the correlation function is not integrable, and the finite variance supOU process may be said to exhibit long-range dependence. On the other
hand, note that the tail distribution of \( \pi \) does not affect the tail behavior of \( r(t) \), and in particular the decay of correlations. Hence it is not very restrictive to assume that (2.6) holds.

In Assumption 2.1(iii), the Lévy measure \( \mu \) is assumed to have a power law behavior near the origin which will give rise to another parameter affecting the limiting behavior. We have excluded a boundary cases \( \gamma = 1 + \alpha \) to simplify the presentation of the results. If (2.7) holds, then \( \beta \) is the Blumenthal-Getoor index of the Lévy measure \( \mu \) defined by (see [19])

\[
\beta_{BG} = \inf \left\{ \gamma \geq 0 : \int_{|x| \leq 1} |x|^{\gamma} \mu(dx) < \infty \right\}.
\]

Note that by [24, Lemma 7.15], \( \mu( (x, \infty)) \sim P(L(1) > x) \) and \( \mu( (-\infty, -x]) \sim P(L(1) \leq -x) \) as \( x \to \infty \), hence we can express (2.10) equivalently as

\[
\mu((x, \infty)) \sim p_{\gamma} x^{-\gamma} \quad \text{and} \quad \mu(( -\infty, -x]) \sim q_{\gamma} x^{-\gamma}, \quad \text{as} \quad x \to \infty.
\] (2.11)

Hence, all the assumptions can be stated in terms of the characteristic quadruple (1.1). The condition (2.7) may be equivalently stated in terms of the Lévy measure of \( X(1) \). Indeed, if \( \nu \) is the Lévy measure of \( X(1) \), then (2.7) is equivalent to (see [19] for details)

\[
\nu((x, \infty)) \sim \beta^{-1} c^+ x^{-\beta} \quad \text{and} \quad \nu(( -\infty, -x]) \sim \beta^{-1} c^- x^{-\beta}, \quad \text{as} \quad x \to 0.
\]

3 Main results

As stated in the introduction, we are interested in establishing the rate of growth of moments of the integrated process (1.2), measured by the scaling function \( \tau_{X^*} \) defined by (1.3). We particularly focus on whether the scaling function exhibits non-linearities. The situation is more delicate than in the finite variance case since the range of finite moments is limited and the scaling function of the integrated process \( X^* \) is well-defined only over the interval \((0, \eta(X^*)) = (0, \gamma)\).

We will show that infinite variance supOU processes may exhibit the phenomenon of intermittency. We first consider the case when the underlying supOU process has no Gaussian component \( (b = 0) \). The obtained scaling functions for this case are shown in Figures 1a–1d.

**Theorem 3.1.** Suppose that Assumption 2.1 holds and \( b = 0 \). Then the scaling function \( \tau_{X^*}(q) \) of the process \( X^* \) is as follows:

(a) If \( \alpha > 1 \) or if \( \alpha \in (0, 1) \) and \( \gamma < 1 + \alpha \), then

\[
\tau_{X^*}(q) = \frac{1}{\gamma} q, \quad 0 < q < \gamma.
\]

(b) If \( \beta < 1 + \alpha < \gamma \), then

\[
\tau_{X^*}(q) = \begin{cases} \frac{1}{1+\alpha} q, & 0 < q \leq 1 + \alpha, \\ q - \alpha, & 1 + \alpha \leq q < \gamma. \end{cases}
\]

(c) If \( 1 + \alpha < \beta \leq \gamma \), then

\[
\tau_{X^*}(q) = \begin{cases} \left( 1 - \frac{\alpha}{\beta} \right) q, & 0 < q \leq \beta, \\ q - \alpha, & \beta \leq q < \gamma. \end{cases}
\]

(d) If \( 1 + \alpha < \gamma < \beta \), then

\[
\tau_{X^*}(q) = \left( 1 - \frac{\alpha}{\beta} \right) q, \quad 0 < q < \gamma.
\]
Figure 1: The scaling functions obtained in Theorems 3.1 \((b = 0)\) and 3.2 \((b \neq 0)\). There is intermittency in the cases (b) and (c).

Note that the scaling function has a change-point in only two of the cases of Theorem 3.1. Hence intermittency appears only in cases (b) and (c) of Theorem 3.1 shown in Figures 1b and 1c, respectively. One can notice that infinite order moments may hide the intermittency property as they limit the domain of the scaling function.
The proof of Theorem 3.1 is given in Subsection 4.3. It is based on the decomposition of the integrated process $X^*$ into independent components $X_1^*$, $X_2^*$ and $X_3^*$ that correspond to characteristic quadruples $(a, 0, \mu(dx)1_{\{|x|>1\}}, \pi)$, $(0, 0, \mu(dx)1_{\{|x|\leq1\}}, \pi)$ and $(0, b, 0, \pi)$, respectively. In Section 4 we derive the scaling functions of $X_1^*$, $X_2^*$ and $X_3^*$ and then combine these to get the scaling function of the integrated process $X^*$. This is illustrated in Figure 2 in Subsection 4.3.

The finite variance component $X_2^*$ exhibits intermittency in all cases, however, this is not always apparent from the scaling function of the process $X^*$. In these cases, the change point in the scaling function of $X_2^*$ is to the right of the moment index $\gamma$ and the scaling function of $X^*$ remains linear on $(0, \gamma)$ (see Figures 2a, 2b, 2c and 2f in Subsection 4.3). Hence, infinite order moments may hide the behavior of the intermittent component.

We next state the result for the supOU process with Gaussian component ($b \neq 0$). The scaling functions for this case are shown in Figures 1e–1f.

**Theorem 3.2.** Suppose that Assumption 2.1 holds and $b \neq 0$. Then the scaling function $\tau_{X^*}(q)$ of the process $X^*$ is as follows:

(a) If $\alpha > 1$ or if $\alpha \in (0, 1)$ and $\gamma < \frac{2}{2-\alpha}$, then

$$\tau_{X^*}(q) = \frac{1}{\gamma}q, \quad 0 < q < \gamma.$$ 

(b) If $\alpha \in (0, 1)$ and $\gamma > \frac{2}{2-\alpha}$, then

$$\tau_{X^*}(q) = \left(1 - \frac{\alpha}{2}\right)q, \quad 0 < q < \gamma.$$ 

Note that if the Gaussian component is present, then the scaling function displays no intermittency. For example, even if the scaling functions of the two components $X_1^*$ and $X_2^*$ have a change-point, this cannot be seen from the scaling function of $X^*$ due to infinite moments (see Figures 4c, 4d, 4e in Subsection 4.3).

4 Proofs

For the proofs of the main results, we first make a decomposition of the integrated process $X^*$ into components that have different limiting behavior. We then compute the scaling functions of these components and finally combine them to get the scaling function of the integrated process.

4.1 The basic decomposition

The decomposition is based on the Lévy-Itô decomposition of the background driving Lévy process $L$. Let

$$\mu_1(dx) = \mu(dx)1_{\{|x|>1\}},$$

$$\mu_2(dx) = \mu(dx)1_{\{|x|\leq1\}},$$

where $\mu$ is the Lévy measure of the Lévy process $L$. Then we can make a decomposition of the Lévy basis into independent components:

- $A_1$ with characteristic quadruple $(a, 0, \mu_1, \pi)$,
- $A_2$ with characteristic quadruple $(0, 0, \mu_2, \pi)$,
- $A_3$ with characteristic quadruple $(0, b, 0, \pi)$. 
Intermittency and infinite variance

Note that if $X(1)$ has finite mean, then the assumption $E X(1) = 0$ implies that $E L(1) = 0$ (see [2, Eq. (2.8)]) and we must have $a = -\int_{|x| > 1} |x| \mu(dx)$ (see e.g. [31, Ex. 25.12]). Let $L_1(t)$, $L_2(t)$ and $L_3(t)$, $t \in \mathbb{R}$ denote the corresponding background driving Lévy processes so that we have the following cumulant functions:

\begin{align*}
C \{ \zeta \mathbb{1}_1 \} &= i \zeta a + \int_{|x| > 1} (e^{i \zeta x} - 1) \mu_1(dx) = i \zeta a + \int_{|x| > 1} (e^{i \zeta x} - 1) \mu(dx), \quad (4.1) \\
C \{ \zeta \mathbb{1}_2 \} &= \int_{\mathbb{R}} (e^{i \zeta x} - 1 - i \zeta x \mathbb{1}_{[1,1]}(x)) \mu_2(dx) \\
&= \int_{|x| \leq 1} (e^{i \zeta x} - 1 - i \zeta x \mathbb{1}_{[-1,1]}(x)) \mu(dx), \\
C \{ \zeta \mathbb{1}_3 \} &= -\frac{\zeta^2}{2} b.
\end{align*}

Note that $L_1$ is a compound Poisson process and $L_3$ is Brownian motion. Consequently, we can represent $X(t)$ as

\begin{align*}
X(t) &= \int_0^\infty \int_{-\infty}^\infty e^{-\xi t + s} \Lambda_1(d\xi, ds) + \int_0^\infty \int_{-\infty}^\infty e^{-\xi t + s} \Lambda_2(d\xi, ds) \\
&\quad + \int_0^\infty \int_{-\infty}^\infty e^{-\xi t + s} \Lambda_3(d\xi, ds) \\
&=: X_1(t) + X_2(t) + X_3(t),
\end{align*}

with $X_1$, $X_2$ and $X_3$ independent. In the following, $X_1^*$, $X_2^*$ and $X_3^*$ will denote the corresponding integrated processes which are independent.

Before we proceed, we note here two technical facts that will be used in the proofs below. The first is a stochastic Fubini theorem related to the change of the order of integration for the integrated process. It has been used implicitly in many references (see e.g. [2, 17, 19]).

**Lemma 4.1.** For the integrated supOU process $X^*$ one has

\begin{align*}
X^*(t) &= \int_0^t \left( \int_{\mathbb{R}^+ \times \mathbb{R}} f(u, \xi, s) \Lambda(d\xi, ds) \right) du = \int_{\mathbb{R}^+ \times \mathbb{R}} \left( \int_0^t f(u, \xi, s) du \right) \Lambda(d\xi, ds), \quad a.s. \quad (4.3)
\end{align*}

where $f(u, \xi, s) = e^{\xi u + s} 1_{[0, \infty)}(\xi u - s)$.

**Proof.** If $E|X(1)| < \infty$, then we can directly use a stochastic Fubini theorem given in [3, Theorem 3.1]. The conditions of Theorem 3.1 and Remark 3.2 in [3, Theorem 3.1] boil down to showing that

(i) for every $u \in [0, t]$, $f(u, \cdot, \cdot)$ is in the Musielak-Orlicz space $L_{\phi_1}$, that is

\begin{align*}
\int_0^\infty \int_{-\infty}^\infty \left( \sigma^2 f(u, \xi, s)^2 + \int_{\mathbb{R}} (|xf(u, \xi, s)|^2 \wedge |xf(u, \xi, s)|) \mu(dx) \right) \pi(d\xi) ds < \infty,
\end{align*}

(ii) it holds that

\begin{align*}
\int_0^t \int_0^\infty \int_{-\infty}^\infty \left( \sigma^2 f(u, \xi, s)^2 + \int_{\mathbb{R}} (|xf(u, \xi, s)|^2 \wedge |xf(u, \xi, s)|) \mu(dx) \right) \pi(d\xi) ds du < \infty.
\end{align*}

By [30, Theorem 3.3], $L_{\phi_1}$ coincides with the space of $\Lambda$-integrable functions $g$ such that $E|f g d\Lambda| < \infty$. Theorem 3.1 of [2] shows that $f(u, \cdot, \cdot)$ is $\Lambda$-integrable and since we have
assumed $E|X(u)| < \infty$, we conclude that condition (i) holds. By the change of variables $r = e^{-\xi u + s}$ we get
\[
\int_0^t \int_{\mathbb{R}^+ \times \mathbb{R}} \left( \sigma^2 e^{2(-\xi u + s)} 1_{[0,\infty)}(\xi u - s) \right) \pi(d\xi)dsdu = \int_0^t \int_{\mathbb{R}^+ \times \mathbb{R}} \left( \sigma^2 r^2 1_{[0,1)}(r) + \int_\mathbb{R} (|r|^2 \land |r|) 1_{[0,1)}(r) \mu(dx) \right) \pi(d\xi)drdu
\]
\[
= \int_0^t \int_{\mathbb{R}^+ \times \mathbb{R}} \left( \sigma^2 r^2 1_{[0,1)}(r) + \int_\mathbb{R} (|r|^2 \land |r|) 1_{(1,\infty)}(r) \mu(dx) \right) \pi(d\xi)r^{-1}drdu
\]
\[
= t \int_0^t \int_{\mathbb{R}^+ \times \mathbb{R}} \left( \sigma^2 r^2 1_{[0,1)}(r) + \int_\mathbb{R} (|r|^2 \land |r|) 1_{[0,1)}(r) \mu(dx) \right) \pi(d\xi)r^{-1}dr
\]
\[
= t \int_0^t \int_{-\infty}^{\infty} \left( \sigma^2 f(u,\xi,s)^2 + \int_\mathbb{R} (|xf(u,\xi,s)|^2 \land |xf(u,\xi,s)|) \mu(dx) \right) \pi(d\xi)ds,
\]
hence, (ii) follows from (i).

Suppose now that $E|X(1)| = \infty$. We can decompose the Lévy basis similarly as in (4.2) into independent Lévy basis $\Lambda'$ with characteristic quadruple $(0,0,\mu_1,\pi)$, $\mu_1(dx) = \mu(dx)1_{(|x|>1)}$, and $\Lambda_2'$ with characteristic quadruple $(a,b,\mu_2,\pi)$, $\mu_2(dx) = \mu(dx)1_{(|x|\leq 1)}$. For the integral with respect to $\Lambda_2$ we can apply [3, Theorem 3.1] as in the previous case. It remains to consider $\Lambda_1$, which is a compound Poisson random measure and can be written as
\[
\Lambda_1(A) = \int_A \int_\mathbb{R} xN(dw,dx),
\]
where $N$ is a Poisson random measure on $\mathbb{R}^+ \times \mathbb{R} \times \mathbb{R}$ with intensity $\pi \times \text{Leb} \times \mu_1$. We can represent $\Lambda_1(A)$ as
\[
\Lambda_1(A) = \sum_{k=-\infty}^\infty Z_k \delta_{(R_k,\Gamma_k)}(A),
\]
where $-\infty < \cdots < \Gamma_{-1} < \Gamma_0 \leq 0 < \Gamma_1 < \cdots < \infty$ are the jump times of a Poisson process on $\mathbb{R}$ with intensity $\mu_1(\mathbb{R})$, $(Z_k, k \in \mathbb{Z})$ is an i.i.d. sequence with distribution $\mu_1(dx)/\mu_1(\mathbb{R})$, $(R_k, k \in \mathbb{Z})$ is an i.i.d. sequence with distribution $\pi$ and all three sequences are independent (see e.g. [15]). The supOU process can then be represented as
\[
X(u) = \sum_{k=-\infty}^\infty Z_k e^{-R_ku + \Gamma_k} 1_{[0,\infty)}(R_ku - \Gamma_k)
\]
\[
= \sum_{k=-\infty}^0 Z_k e^{-R_ku + \Gamma_k} + \sum_{k=1}^\infty Z_k e^{-R_ku + \Gamma_k} 1_{[0,\infty)}(R_ku - \Gamma_k).
\]
The second sum has finitely many terms a.s. due to $1_{[0,\infty)}(R_ku - \Gamma_k)$ term, hence one can change the order of integration when integrating with respect to $u$. For the first sum, we have by using the inequality $(1 - e^{-x})/x \leq 1$, $x > 0$,
\[
\sum_{k=-\infty}^0 \int_0^t |Z_k|e^{-R_ku + \Gamma_k} du = \sum_{k=-\infty}^0 |Z_k|e^{\Gamma_k} R_k^{-1}(1 - e^{-R_k t}) \leq t \sum_{k=-\infty}^\infty |Z_k|e^{\Gamma_k}.
\]
The right-hand side is finite since it is the integral of $e^{-x}$ with respect to compound Poisson random measure with intensity $\text{Leb} \times |\mu_1|$ (see e.g. [25]). By the classical Fubini-Tonelli theorem we can change the order of integration. This completes the proof of (4.3).\]
Intermittency and infinite variance

The second fact concerns again $X^*(t)$ in (4.3). Clearly $E|X^*(t)|^q < \infty$ for $q < \gamma$. The next lemma shows that $E|X^*(t)|^q = \infty$ for $q > \gamma$.

**Lemma 4.2.** If the supOU process $X$ satisfies (2.4) for some $\gamma > 0$, then for the integrated process $X$ we have $E|X^*(t)|^q = \infty$ for $q > \gamma$ and every $t > 0$.

**Proof.** We will show that $E|X^*(t)|^{q+\varepsilon} = \infty$ for $\varepsilon > 0$. By (4.3), $X^*(t)$ is representable as an integral with respect to Lévy basis $\Lambda$

$$X^*(t) = \int_{\mathbb{R}_+ \times \mathbb{R}} g_t(\xi, s)\Lambda(d\xi, ds).$$

where

$$g_t(\xi, s) = \int_0^t e^{-\xi u + s}1_{[0,\infty)}(\xi u - s)du = \begin{cases} e^{s\xi^{-1}}(1 - e^{-\xi t}), & s < 0, \\ \xi^{-1}(1 - e^{-\xi t + s}), & 0 < s < \xi t. \end{cases}$$

Hence, by [30, Theorem 2.7], the distribution of $X^*(t)$ is infinitely divisible and for Borel set $B \subseteq \mathbb{R}$, the Lévy measure $\mu_{g_t}$ of $X^*(t)$ is given by

$$\mu_{g_t}(B) = \pi \times \text{Leb} \times \mu \{ \{\xi, s, x\} : g_t(\xi, s)x \in B \setminus \{0\}\}.$$  

In particular, for $y > 0$ and $B = [y, \infty)$, we have

$$\mu_{g_t}([y, \infty)) = \int_0^\infty \int_{-\infty}^\infty \mu([y/g_t(\xi, s), \infty))\pi(d\xi)ds.$$  

From (2.11), which is equivalent to (2.4), one has for any $\delta < \varepsilon$, a $y_0$ such that $\mu([y, \infty)) \geq y^{-\gamma-\delta}$ for $y \geq y_0$. This implies that for $y \geq y_0$, $\mu_{g_t}([y, \infty)) \geq Cy^{-\gamma-\delta}$, where $C = \int_0^\infty \int_{-\infty}^\infty (g_t(\xi, s))^{\gamma+\delta}\pi(d\xi)ds$. The same argument can be used for $\mu(-\infty, -y)$. But this implies that $\int_{\{|y|>1\}} |y|^{\gamma+\varepsilon}\mu_{g_t}(dy) \geq C_1 + C_2 \int_{\{|y|\geq y_0\}} |y|^{\gamma-\delta}\mu_{g_t}(dy) = \infty$, where $C_1$ and $C_2$ are positive constants. Hence, we have $E|X^*(t)|^{q+\varepsilon} = \infty$ (see e.g. [31, Theorem 25.3]).

**4.2 Evaluation of the three scaling functions**

We next investigate the scaling functions of each process $X^*_1$, $X^*_2$ and $X^*_3$ separately. These results will then be combined to give the scaling function of the integrated process.

**4.2.1 The scaling function of $X^*_1$**

The process $X^*_1$ has infinite moments of order greater than $\gamma$ and its scaling function $\tau_{X^*_1}$ is well-defined for $q \in (0, \gamma)$ (see Lemma 4.2). Following [20, Lemma 5.1 and 5.2], two processes may arise as a limit of $X^*_1$ after normalization.

If $\gamma < 1 + \alpha$, then as $T \to \infty$

$$\left\{ \frac{1}{T^{\gamma/k^#(T)^{1/\gamma}}} X^*_1(Tt) \right\} \d\to \{L_\gamma(t)\}, \quad (4.4)$$

where $k$ is the slowly varying function in (2.4), $k^#$ is the de Bruijn conjugate of $1/k(1^{1/\gamma})$ and the limit $\{L_\gamma\}$ is a $\gamma$-stable Lévy process such that $L_\gamma(1) \d\to \tilde{\sigma}_\gamma(\tilde{\sigma}_1, \gamma, \rho, 0)$ with

$$\tilde{\sigma}_1, \gamma = \sigma\left(\gamma \int_0^\infty \xi^{1-\gamma}\pi(d\xi)\right)^{1/\gamma},$$

EJP 26 (2021), paper 56.

https://www.imstat.org/ejp
Intermittency and infinite variance

and $\sigma$ and $\rho$ given by (2.8). Recall that the de Bruijn conjugate [14, Subsection 1.5.7] of some slowly varying function $h$ is a slowly varying function $h^#$ such that

$$h(x)h^#(xh(x)) \to 1, \quad h^#(xh^#(x)) \to 1,$$

as $x \to \infty$. By [14, Theorem 1.5.13] such function always exists and is unique up to asymptotic equivalence.

If, on the other hand $\gamma > 1 + \alpha$, then as $T \to \infty$

$$\left\{ \frac{1}{T^{1/(1+\alpha)}} \ell^#(Y(x)) \right\} \Rightarrow \{L_{1+\alpha}(t)\},$$

(4.5)

where $\ell^#$ is de Bruijn conjugate of $1/\ell(x^{1/(1+\alpha)})$ and the limit $\{L_{1+\alpha}\}$ is $(1+\alpha)$-stable Lévy process such that $L_{1+\alpha}(1) \overset{d}{=} \mathcal{S}_c(\tilde{s}_{\alpha}, \tilde{\rho}_1, 0)$ with

$$\tilde{s}_{\alpha} = \left( \frac{\Gamma(1-\alpha)}{\alpha} (c^-_1 + c^+_1) \cos \left( \frac{\pi(1+\alpha)}{2} \right) \right)^{1/(1+\alpha)}, \quad \tilde{\rho}_1 = \frac{c^-_1 - c^+_1}{c^-_1 + c^+_1},$$

(4.6)

and $c^-_1, c^+_1$ given by

$$c^-_1 = \frac{\alpha}{1+\alpha} \int_{-\infty}^{-1} |y|^{1+\alpha}\mu(dy), \quad c^+_1 = \frac{\alpha}{1+\alpha} \int_{1}^{\infty} y^{1+\alpha}\mu(dy).$$

(4.7)

We now consider convergence of moments in these limit theorems. First, if $\gamma < 1 + \alpha$, then we get the following scaling function for the process $X^*_1$.

**Lemma 4.3.** If Assumption 2.1 holds and $\gamma < 1 + \alpha$, then

$$\tau_{X^*_1}(q) = \frac{1}{\gamma} q, \quad 0 < q < \gamma.$$

Proof. Let $q < \gamma$ and $A_T = T^{1/\gamma}k^#(T)^{1/\gamma}$. We will show that $\{|A_T^{-1}X^*_1(T)|^q\}$ is uniformly integrable so that $E|A_T^{-1}X^*_1(T)|^q \to E|L_\gamma(t)|^q$ as $T \to \infty$, where $\{L_\gamma\}$ is as in (4.4).

First we recall some known results. If $Y$ is some random variable, let $\tilde{Y}$ denote its symmetrization, i.e. $\tilde{Y} = Y - Y'$ with $Y' = d Y$ and independent of $Y$. By [35, Lemma 4], if $r \in [1, 2]$, $E|Y|^r < \infty$ and $EY = 0$, then

$$E|Y|^r \leq E|\tilde{Y}|^r.$$  

(4.8)

On the other hand, if $r < 1$ and $E|Y|^r < \infty$, then we obtain from [21, Proposition 3.6.4] that

$$E|Y|^r \leq 2E|\tilde{Y}|^r + 2|\text{med}(Y)|^r,$$  

(4.9)

where $\text{med}(Y)$ denotes the median of $Y$. Furthermore, one may express $r$-th absolute moment, $0 < r < 2$ as [35, Lemma 2]

$$E|Y|^r = k_r \int_{-\infty}^{\infty} (1 - |\Re \kappa_Y(\zeta)|) \zeta^{-r-1} d\zeta$$  

(4.10)

where $k_r > 0$ is a constant.

Consider now the symmetrized random variable $X^*_1(Tt)$. The characteristic function of $X^*_1(Tt)$ is $|\exp \kappa_{X^*_1}(\zeta, Tt)|^2$, hence from (4.10) we get

$$E|A_T^{-1}X^*_1(T)|^q = k_q \int_{-\infty}^{\infty} (1 - |\exp \kappa_{X^*_1}(A_T^{-1}\zeta, Tt)|^2) \zeta^{-q-1} d\zeta.$$

(4.11)
Intermittency and infinite variance

In order to bound the integral in (4.11), we shall first derive the bounds for $|\kappa_{X_1}(A_T^{-1} \zeta, T)|$. For this we make the decomposition from (2.2) by using Lemma 4.1:

$$X_1(T) = \int_{u=0}^{T} \int_{s=-\infty}^{\infty} e^{-\xi u + s} \Lambda_1(d\xi, ds) du$$

$$= \int_{u=0}^{T} \int_{s=-\infty}^{0} e^{-\xi u + s} du \Lambda_1(d\xi, ds) + \int_{u=0}^{T} \int_{s=0}^{\infty} e^{-\xi u + s} du \Lambda_1(d\xi, ds)$$

$$= \int_{s=-\infty}^{0} \int_{u=0}^{T} e^{-\xi u + s} du \Lambda_1(d\xi, ds) + \int_{s=0}^{\infty} \int_{u=0}^{T} e^{-\xi u + s} du \Lambda_1(d\xi, ds)$$

(4.12)

Now we consider bounds for each term separately.

- For the first term on the right hand side we use some parts of the proof of [20, Lemma 5.1]. From the integration formula for the stochastic integral, for any $\Lambda$-integrable function $f$ on $\mathbb{R} \times \mathbb{R}$, one has (see [30])

$$C \left\{ \zeta + \int_{\mathbb{R} \times \mathbb{R}} f d\Lambda \right\} = \int_{\mathbb{R} \times \mathbb{R}} \kappa_L(\zeta f(\xi, s)) ds \tau(d\xi)$$

(4.14)

and we get that

$$\kappa_{\Delta X_1,1}(A_T^{-1} \zeta, T) = \int_{0}^{\infty} \int_{-\infty}^{0} \kappa_{L_1} \left( \zeta A_T^{-1} \int_{0}^{T} e^{-\xi u + s} du \right) ds \tau(d\xi)$$

(4.15)

The assumption (2.10), together with [22, Theorem 2.6.4], imply that

$$\kappa_{L_1}(\zeta) \sim k(1/|\zeta|) \kappa_{\delta, (\gamma^1/\sigma, 0)}(\zeta), \quad \text{as } \zeta \to 0.$$  

(4.16)

Since $|\kappa_{\delta, (\gamma^1/\sigma, 0)}(\zeta)| = C|\zeta|^\gamma$ and $k$ is slowly varying at infinity, then, for arbitrary $\delta > 0$, in some neighborhood of the origin one has

$$|\kappa_{L_1}(\zeta)| \leq C_1 |\zeta|^{-\delta}, \quad |\zeta| \leq \varepsilon.$$

On the other hand, since $|e^{i \xi x} - 1| \leq 2$, we have from (4.1) that

$$|\kappa_{L_1}(\zeta)| \leq |a||\zeta| + 2 \int_R 1_{\{|x| > 1\}} \mu(dx) \leq |a||\zeta| + C_2,$$

since the Lévy measure is integrable on $\{|x| > 1\}$. By taking $C_3$ large enough we arrive at the bound

$$|\kappa_{L_1}(\zeta)| \leq C_1 |\zeta|^{-\delta} 1_{\{|\zeta| \leq \varepsilon\} + C_3 |\zeta| 1_{\{|\zeta| > \varepsilon\}}.$$  

(4.17)
Now we have from (4.15)

\[
\left| k_{\Delta X_{1}^{	au}}(A_{T}^{-1}\xi, T) \right| \\
\leq C_{1}\int_{0}^{\infty} \int_{-\infty}^{0} |\xi| A_{T}^{-1}e^{\xi-1} (1 - e^{-\xi T}) |^{\gamma-\delta} 1_{\{ |\xi| A_{T}^{-1}e^{\xi-1} (1 - e^{-\xi T}) \leq e \}} ds \pi(d\xi) \\
+ C_{3}\int_{0}^{\infty} \int_{-\infty}^{0} |\xi| A_{T}^{-1}e^{\xi-1} (1 - e^{-\xi T}) |^{\gamma-\delta} 1_{\{ |\xi| A_{T}^{-1}e^{\xi-1} (1 - e^{-\xi T}) > e \}} ds \pi(d\xi) \\
\leq C_{1}|\xi|^{\gamma-\delta} A_{T}^{\gamma+\delta} \int_{0}^{\infty} \int_{0}^{\infty} e^{(\gamma-\delta)s} (\xi^{-1} (1 - e^{-\xi T}))^{\gamma-\delta} ds \pi(d\xi) \\
+ C_{3}|\xi|A_{T}^{-1}T \int_{0}^{\infty} \int_{0}^{\infty} e^{s} (\xi T)^{-1} (1 - e^{-\xi T}) 1_{\{ |\xi| A_{T}^{-1} (1 - e^{-\xi T}) > e \}} ds \pi(d\xi) \\
\leq C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} \int_{0}^{\infty} (\xi T)^{-1} (1 - e^{-\xi T}) \pi(d\xi) \\
+ C_{3}\frac{1}{\gamma-\delta}|\xi|A_{T}^{-1} T \int_{0}^{\infty} (\xi T)^{-1} (1 - e^{-\xi T}) 1_{\{ |\xi| A_{T}^{-1} (1 - e^{-\xi T}) > e \}} \pi(d\xi).
\]

We consider now each term separately. For the first term we proceed as in the proof of [20, Lemma 5.1]. If \( \gamma \in (0, 1) \), then from the inequality \( x^{-1} (1 - e^{-x}) \leq 1, x > 0 \), we get

\[
C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} A_{T}^{\gamma+\delta} \int_{0}^{\infty} ((\xi T)^{-1} (1 - e^{-\xi T}))^{\gamma-\delta} \pi(d\xi) \\
\leq C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} T^{\gamma-1 + \delta/\gamma} k^{\#}(T)^{-\gamma + \delta/\gamma} \\
\leq C_{4}|\xi|^{\gamma-\delta},
\]

since \( T^{\gamma-1 + \delta/\gamma} k^{\#}(T)^{-\gamma + \delta/\gamma} \to 0 \) as \( T \to \infty \), due to \( \gamma - \delta - 1 + \delta/\gamma < 0 \). If \( \gamma \in (1, 2) \), then from the inequality \( x^{-1} (1 - e^{-x}) \leq x^{1-\gamma/(\gamma-\delta)} \) it follows

\[
C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} A_{T}^{\gamma+\delta} \int_{0}^{\infty} ((\xi T)^{-1} (1 - e^{-\xi T}))^{\gamma-\delta} \pi(d\xi) \\
\leq C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} T^{\gamma-1 + \delta/\gamma} k^{\#}(T)^{-\gamma + \delta/\gamma} \int_{0}^{\infty} (\xi T)^{-1} \pi(d\xi) \\
\leq C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} T^{\gamma-1 + \delta/\gamma} k^{\#}(T)^{-\gamma + \delta/\gamma} \int_{0}^{\infty} \xi^{\gamma-1} \pi(d\xi) \\
\leq C_{5}|\xi|^{\gamma-\delta},
\]

since \( T^{\gamma-1 + \delta/\gamma} k^{\#}(T)^{-\gamma + \delta/\gamma} \to 0 \) as \( T \to \infty \) and \( \int_{0}^{\infty} \xi^{\gamma-1} \pi(d\xi) < \infty \) due to (2.6). For \( \gamma = 1 \) case we may use the fact that \( x^{-1} (1 - e^{-x}) \leq x^{-\eta/(\gamma-\delta)}, \eta > 0 \), to obtain

\[
C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} A_{T}^{\gamma+\delta} \int_{0}^{\infty} ((\xi T)^{-1} (1 - e^{-\xi T}))^{\gamma-\delta} \pi(d\xi) \\
\leq C_{1}\frac{1}{\gamma-\delta}|\xi|^{\gamma-\delta} T^{1-\varepsilon} k^{\#}(T)^{-\gamma + \delta/\gamma} \int_{0}^{\infty} \xi^{\gamma-\varepsilon} \pi(d\xi) \\
\leq C_{6}|\xi|^{\gamma-\delta}.
\]

Returning now to the second term (4.19), from the inequality \( x^{-1} (1 - e^{-x}) \leq 1, x > 0 \),
we get
\[ C_3 \int_0^\infty (\xi T)^{-1} (1 - e^{-\xi T}) 1_{(\xi T)^{-1}(1 - e^{-\xi T}) > \varepsilon} \pi(d\xi) \leq C_3 \int_0^\infty (\xi T)^{-1} (1 - e^{-\xi T}) 1_{(\xi T)^{-1}(1 - e^{-\xi T}) > \varepsilon} \pi(d\xi) \leq C_3 \int_0^\infty (\xi T)^{-1} (1 - e^{-\xi T}) \pi(d\xi) \leq C_3 \int_0^\infty (\xi T)^{-1} \pi((0, e^{-1}A_T^{-1}T)) \]

By (2.5), for arbitrary \( 0 < \eta < 1 + \alpha - \gamma \), in some neighborhood of the origin it holds that \( \pi((0, x)) \leq C_\gamma x^{\alpha - \eta} \). Hence we have
\[ C_3 \int_0^\infty (\xi T)^{-1} (1 - e^{-\xi T}) 1_{(\xi T)^{-1}(1 - e^{-\xi T}) > \varepsilon} \pi(d\xi) \leq C_3 \int_0^\infty (\xi T)^{-1} (1 - e^{-\xi T}) 1_{(\xi T)^{-1}(1 - e^{-\xi T}) > \varepsilon} \pi(d\xi) \leq C_3 \int_0^\infty (\xi T)^{-1} \pi((0, e^{-1}A_T^{-1}T)) \]

since \( 1 + \alpha > \gamma \). We conclude finally from (4.18)–(4.19) that the following bound holds
\[ |\kappa \Delta X_t^\gamma_t (A_T^{-1}T, Tt)| \leq C_0 H_{\gamma}^\gamma \kappa \Delta X_t^\gamma_t (A_T^{-1}T, Tt) \leq \left\{ \begin{array}{ll}
C_{10} |\gamma - \delta|, & |\gamma| \leq 1,
C_{11} |\gamma|^{1 + \alpha - \eta}, & |\gamma| > 1.
\end{array} \right. \]

(4.20)

- We now consider \(|\kappa \Delta X_t^\gamma_t (A_T^{-1}T, Tt)|\) in (4.13). Because of (4.16) we can write
\[ \kappa \Delta X_t^\gamma_t (A_T^{-1}T, Tt) = \kappa_{S_t(\gamma, \sigma, \rho, 0)}(\xi) \]

where \( k \) is slowly varying at zero such that \( k(\xi) \sim k(1/\xi) \) as \( \xi \to 0 \) and \( \kappa_{S_t(\gamma, \sigma, \rho, 0)} \) is a cumulant function of a stable distribution as in (2.3). By [20, Eq. (34)] we have that
\[ \kappa \Delta X_t^\gamma_t (A_T^{-1}T, Tt) = \kappa_{S_t(\gamma, \sigma, \rho, 0)}(\xi) \times \int_0^\infty \int_0^\xi \xi^{-\gamma} \left( 1 - e^{-\xi T(t-s)} \right)^{\gamma} E \left( (Tk^\#(T))^{-1/\gamma} \xi^{-1} \left( 1 - e^{-\xi T(t-s)} \right) \right) \frac{k^\#(T)}{k^\#(T)} ds \pi(d\xi). \]

(4.21)
The definition of \( k^\# \) implies that [14, Theorem 1.5.13]
\[ \frac{k^\#(T)}{k} \left( \frac{k^\#(T)}{k} \right)^{-1/\gamma} \sim \frac{k^\#(T)}{k} \left( \frac{k^\#(T)}{k} \right)^{1/\gamma} \to 1 \quad \text{as} \quad T \to \infty, \]

and due to slow variation of \( E \), for any \( \xi \in \mathbb{R} \), \( \xi > 0 \) and \( s \in (0, t) \), as \( T \to \infty \)
\[ \frac{k^\#(T)}{k} \left( \frac{k^\#(T)}{k} \right)^{-1/\gamma} \xi^{-1} \left( 1 - e^{-\xi T(t-s)} \right) \xi^{-1} \left( 1 - e^{-\xi T(t-s)} \right) \to \frac{k^\#(T)}{k} \left( \frac{k^\#(T)}{k} \right)^{-1/\gamma} \to 1. \]

(4.22)
Intermittency and infinite variance

By using Potter’s bounds (see [14, Theorem 1.5.6]), we have from (4.22) that for any \( \varepsilon > 0 \)
\[
\frac{\mathbb{E} \left( (Tk^#(T))^{-1/\gamma} \zeta^{-1} \left( 1 - e^{-\xi T(t-s)} \right) \right)}{k^#(T)} \leq C_{12} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \left( 1 - e^{-\xi T(t-s)} \right)^{-\varepsilon} \right\} 
\leq C_{12} \left( 1 - e^{-\xi T(t-s)} \right)^{-\varepsilon} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\},
\]
for \( T \) large enough. By taking \( \varepsilon < \gamma \) we get
\[
\xi^{1-\gamma} \left( 1 - e^{-\xi T(t-s)} \right) \frac{\mathbb{E} \left( (Tk^#(T))^{-1/\gamma} \zeta^{-1} \left( 1 - e^{-\xi T(t-s)} \right) \right)}{k^#(T)} \leq C_{12} \xi^{1-\gamma} \left( 1 - e^{-\xi T(t-s)} \right)^{\gamma-\varepsilon} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\} \leq C_{12} \xi^{1-\gamma} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\}.
\]
Since \( \gamma < 1 + \alpha \) and (2.6) holds, we have
\[
\int_0^\infty \int_0^t \xi^{1-\gamma} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\} ds \pi(d\xi) = t \int_0^1 \xi^{1-\gamma-\varepsilon} \pi(d\xi) + t \int_1^\infty \xi^{1-\gamma+\varepsilon} \pi(d\xi) < \infty.
\]
We finally conclude from (4.21) that
\[
|\kappa_{\Delta X^*_1} (A_{T^{-1}} \zeta, Tt)| \leq C_{13} |\kappa_{\delta, \gamma} (\gamma, \sigma, \rho, 0) (\zeta)| \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\} \leq C_{14} |\zeta|^{-\varepsilon} \max \left\{ \xi^{-\varepsilon}, \xi^{-\varepsilon} \right\}.
\]

- We shall now put the bounds for the terms in (4.13) together. By using (4.20) and (4.23) one has from (4.13) that
\[
|\kappa_{X^*_1} (A_{T^{-1}} \zeta, Tt)| \leq \begin{cases} C_{10} |\zeta|^{\gamma-\delta} + C_{14} |\zeta|^{-\varepsilon}, & |\zeta| \leq 1, \\ C_{11} |\zeta|^{1+\alpha-\eta} + C_{14} |\zeta|^{\gamma+\varepsilon}, & |\zeta| > 1. \end{cases}
\]
Since \( \gamma < 1 + \alpha \) and \( \varepsilon, \delta \) and \( \eta \) are arbitrary, we may choose them so that \( \varepsilon < \delta < \gamma - q \) and \( 1 + \alpha - \eta > \gamma + \varepsilon \), hence
\[
|\kappa_{X^*_1} (A_{T^{-1}} \zeta, Tt)| \leq \begin{cases} C_{15} |\zeta|^{\gamma-\delta}, & |\zeta| \leq 1, \\ C_{16} |\zeta|^{1+\alpha-\eta}, & |\zeta| > 1. \end{cases}
\]
This completes the derivation of the bound for \( |\kappa_{X^*_1} (A_{T^{-1}} \zeta, Tt)| \).

- We now turn to (4.11) to get a bound for the moment \( \mathbb{E} \left| A_{T^{-1}} X^*_1 (Tt) \right|^q \). We use (4.11), (4.24) and
\[
|\exp \kappa_{X^*_1} (A_{T^{-1}} \zeta, Tt)\rangle^2 = \exp \{ 2 \Re \kappa_{X^*_1} (A_{T^{-1}} \zeta, Tt) \} \geq \exp \{ -2 |\kappa_{X^*_1} (A_{T^{-1}} \zeta, Tt)| \},
\]

EJP 26 (2021), paper 56.
https://www.imstat.org/ejp
Page 16/31
We now derive bound for $EJP$ bound. We will prove that Lemma 4.3. We first consider the case $\gamma > 1$. For $\gamma > 1$, we conclude that the convergence of moments. Since the limiting process is right. This completes the proof of uniform integrability of $\{\kappa_{\Delta X_t}(A_T^{-1}\zeta, Tt)\}$. Hence we can bound the second term on the right. This completes the proof of uniform integrability of $\{\kappa_{\Delta X_t}(A_T^{-1}\zeta, Tt)\}$, hence the convergence of moments. Since the limiting process is $1/\gamma$-self-similar, from [17, Theorem 1] we conclude that

$$\tau_{\Delta X_t}(q) = \frac{1}{\gamma} q, \text{ for } q < \gamma.$$  

For $\gamma > 1 + \alpha$ we have the following.

**Lemma 4.4.** If Assumption 2.1 holds and $\gamma > 1 + \alpha$, then

$$\tau_{\Delta X_t}(q) = \frac{1}{\gamma + \alpha} q, \text{ for } 0 < q \leq 1 + \alpha, \quad \leq q - \alpha, \quad 1 + \alpha < q < \gamma. \quad (4.26)$$

**Proof.** We first consider the case $q < 1 + \alpha$. The proof is similar to the proof of Lemma 4.3. We will prove that $\{\kappa_{\Delta X_t}(A_T^{-1}\zeta, Tt)\}$ is uniformly integrable where now $A_T = T^{1/(1+\alpha)}(T)$. We can assume $q > 1$. From (4.8), (4.11) and (4.25) it follows that

$$E \left| A_T^{-1} X_t(T) \right|^q \leq E \left| A_T^{-1} \Delta X_t(T) \right|^q$$

$$\leq kq \int_{-\infty}^{\infty} (1 - \exp\{-2|\kappa_{X_t}(A_T^{-1}\zeta, Tt)|\}) \, |\zeta|^{-\gamma - 1} d\zeta. \quad (4.27)$$

We now derive bound for $|\kappa_{\Delta X_{t,1}}(A_T^{-1}\zeta, Tt)|$. Again we use the decomposition (4.12) and bound $|\kappa_{\Delta X_{t,2}}(A_T^{-1}\zeta, Tt)|$ and $|\kappa_{\Delta X_{t,3}}(A_T^{-1}\zeta, Tt)|$ separately.
Intermittency and infinite variance

- We consider first $\kappa_{\Delta X^{-1}_{\ell_{1}}}(A^{-1}_{T} \zeta, T t)$. From (4.17) we also have the following bound for $\varepsilon < 1 + \alpha - q$

$$|\kappa_{L_{1}}(\zeta)| \leq C_{1}|\zeta|^{1+\alpha-\varepsilon},$$

and by using Potter’s bounds we have for $0 < \delta < \varepsilon \alpha/(1 + \alpha)$

$$\tilde{\ell}(T \xi^{-1}) = \frac{\tilde{\ell}(T \xi^{-1})}{\ell(\xi^{-1})} \leq C_{2} \max \{T^{-\delta}, T^{\delta}\} \tilde{\ell}(\xi^{-1}).$$

By (2.5), we can write the density $p$ of $\pi$ in the form $p(x) = \alpha \ell(x^{-1}) x^{\alpha-1}$ with $\ell$ slowly varying at infinity such that $\ell(t) \sim \ell(t)$ as $t \to \infty$. Hence from (4.15) we have

$$\kappa_{\Delta X^{-1}_{\ell_{1}}}(A^{-1}_{T} \zeta, T t) = \int_{0}^{\infty} \int_{-\infty}^{\infty} \kappa_{L_{1}} \left( \zeta A^{-1}_{T} T e^{\xi^{-1}} (1 - e^{-\xi t}) \right) d s \pi(T^{-1} d \xi)$$

$$= \int_{0}^{\infty} \int_{-\infty}^{\infty} \kappa_{L_{1}} \left( \zeta A^{-1}_{T} T e^{\xi^{-1}} (1 - e^{-\xi t}) \right) \alpha \ell(T^{-1}) \xi^{\alpha-1} t^{-\alpha} d s d \xi,$$

and

$$\kappa_{\Delta X^{-1}_{\ell_{1}}}(A^{-1}_{T} \zeta, T t) \leq C_{3} \xi^{1+\alpha-\varepsilon-T^{-1/(1+\alpha)}+1+\alpha-\varepsilon+\alpha+\delta \ell^\#(T)^{-1/(1+\alpha)}$$

$$\times \int_{0}^{\infty} \int_{-\infty}^{\infty} e^{\xi^{-1}} (1 - e^{-\xi t})^{1+\alpha-\varepsilon} \tilde{\ell}(\xi^{-1}) \xi^{\alpha-1} d s d \xi,$$

$$\leq C_{3} \xi^{1+\alpha-\varepsilon-T^{-1/(1+\alpha)}+\delta \ell^\#(T)^{-1/(1+\alpha)} \int_{0}^{\infty} \tilde{\ell}(\xi^{-1}) \xi^{\alpha-1} d \xi,$$

$$\leq C_{4} \xi^{1+\alpha-\varepsilon}. \hspace{1cm} (4.28)$$

- We consider now $|\kappa_{\Delta X^{-1}_{\ell_{1}}}(A^{-1}_{T} \zeta, T t)|$. Analogous to (4.15) we obtain

$$\kappa_{\Delta X^{-1}_{\ell_{1}}}(A^{-1}_{T} \zeta, T t) = \int_{0}^{\infty} \int_{0}^{t} \kappa_{L_{1}} \left( \zeta A^{-1}_{T} \xi^{-1} (1 - e^{-\xi t}) \right) \xi T d \pi(d \xi)$$

$$= \int_{0}^{\infty} \int_{0}^{t} \kappa_{L_{1}} \left( \zeta A^{-1}_{T} \xi^{-1} (1 - e^{-\xi t}) \right) \alpha \ell(\xi^{-1}) \xi^{\alpha} T d \xi d s.$$
Intertmittency and infinite variance

Hence, for $T$ large enough

$$\tilde{\ell}\left( T^{1/(1+\alpha)} \ell^# \left( T \right)^{1/(1+\alpha)} x^{-\zeta-1} \right) \leq C_2 \max \{ x^{-\eta} \zeta, x^{-\eta} \zeta^{-\eta} \},$$

and by inserting this in (4.29) we get

$$\left| \kappa_{\Delta X_{T}^{1,2}}(A_{T}^{-1} \zeta, Tb) \right| \leq \alpha C_2 \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \times \int_{0}^{\infty} \int_{0}^{t} |\kappa_{L}(x (1 - g_T(\zeta, x, s))| \max \{ x^{-\eta}, x^{\eta} \} x^{-\alpha-2} dsdx.$$

Now we use the bound (4.17) valid for arbitrary $\delta > 0$ to obtain

$$\left| \kappa_{\Delta X_{T}^{1,2}}(A_{T}^{-1} \zeta, Tb) \right| \leq C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \int_{0}^{\infty} \int_{0}^{t} (x (1 - g_T(\zeta, x, s)) |\zeta^{\gamma-\delta} \times 1_{\{x(1-g_T(\zeta,x,s)) \leq \epsilon \}} \max \{ x^{-\eta}, x^{\eta} \} x^{-\alpha-2} dsdx 
+ C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \int_{0}^{\infty} \int_{0}^{t} x (1 - g_T(\zeta, x, s)) \times 1_{\{x(1-g_T(\zeta,x,s)) > \epsilon \}} \max \{ x^{-\eta}, x^{\eta} \} x^{-\alpha-2} dsdx =: I_1 + I_2.$$

We consider each term separately.

- For $I_1$ we make change of variables $y = x (1 - g_T(\zeta, x, s))$ and get

$$I_1 = C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \int_{0}^{\infty} \int_{0}^{t} y^{\gamma-\delta} 1_{\{y \leq \epsilon \}} \times \max \left\{ y^{-\eta} (1 - g_T(\zeta, x, s))^{\eta}, y^{\eta} (1 - g_T(\zeta, x, s))^{-\eta} \right\} y^{-\alpha-2} \times (1 - g_T(\zeta, x, s))^{\alpha+1} dsdy 
\leq C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \int_{0}^{\infty} \int_{0}^{t} y^{\gamma-\alpha-2-\delta-\eta} 1_{\{y \leq \epsilon \}} (y) \times (1 - g_T(\zeta, x, s))^{\alpha+1-\eta} dsdy 
\leq C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \int_{0}^{\infty} y^{\gamma-\alpha-2-\delta-\eta} dy 
= C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \},$$

where we have used the fact that the integral in the last line is finite due to $\gamma > 1 + \alpha$ and the choice of $\eta$ and $\delta$.

- Consider now $I_2$. Since $x (1 - g_T(\zeta, x, s)) > \epsilon$ implies $x > \epsilon$, we have for $I_2$,

$$I_2 \leq C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \int_{0}^{\infty} \int_{0}^{x} x^{-\alpha-1} 1_{\{x > \epsilon \}} \max \{ x^{-\eta}, x^{\eta} \} dsdx 
\leq C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \} \int_{\epsilon}^{\infty} x^{-\alpha-1+\eta} dx 
= C_\delta \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \}.$$

Returning back to (4.30) we conclude that

$$\left| \kappa_{\Delta X_{T}^{1,2}}(A_{T}^{-1} \zeta, Tb) \right| \leq C_{10} \zeta^{1+\alpha} \max \{ \zeta^{\eta}, \zeta^{-\eta} \}.$$
From (4.13), (4.28) and (4.31) we get the bound for $|\kappa_{X^*_1}(A_T^{-1} \zeta, Tt)|$. Namely, for $\varepsilon > 0$ and $\eta > 0$ arbitrary small there are constants $C_1, C_2 > 0$ such that

$$|\kappa_{X^*_1}(A_T^{-1} \zeta, Tt)| \leq \begin{cases} C_1|\zeta|^{1+\alpha-\varepsilon} + C_2|\zeta|^{1+\alpha-\eta}, & |\zeta| \leq 1, \\ C_1|\zeta|^{1+\alpha-\varepsilon} + C_2|\zeta|^{1+\alpha+\eta}, & |\zeta| > 1. \end{cases}$$

Assuming e.g. that $\varepsilon < \eta$ we have

$$|\kappa_{X^*_1}(A_T^{-1} \zeta, Tt)| \leq \begin{cases} C_3|\zeta|^{1+\alpha-\eta}, & |\zeta| \leq 1, \\ C_4|\zeta|^{1+\alpha+\eta}, & |\zeta| > 1. \end{cases}$$

We use this to get the bound for the $q$-th absolute moment as in the proof of Lemma 4.3. It follows from (4.27) that

$$E|X^*_1(1+\alpha)\leq q \int_{|\zeta| \leq 1} \left(1 - \exp\{-2C_3|\zeta|^{1+\alpha-\eta}\}\right)|\zeta|^{-q-1}d\zeta$$

$$+ k_q \int_{|\zeta| > 1} \left(1 - \exp\{-2C_4|\zeta|^{1+\alpha+\eta}\}\right)|\zeta|^{-q-1}d\zeta$$

$$\leq k_q \int_{-\infty}^{\infty} \left(1 - \exp\{-2C_3|\zeta|^{1+\alpha-\eta}\}\right)|\zeta|^{-q-1}d\zeta$$

$$+ k_q \int_{-\infty}^{\infty} \left(1 - \exp\{-2C_4|\zeta|^{1+\alpha+\eta}\}\right)|\zeta|^{-q-1}d\zeta.$$  

The terms on the right-hand side are $q$-th absolute moments of $(1+\alpha-\eta)$-stable and $(1+\alpha+\eta)$-stable random variables with characteristic functions $\exp\{-2C_3|\zeta|^{1+\alpha-\eta}\}$ and $\exp\{-2C_4|\zeta|^{1+\alpha+\eta}\}$, respectively. We are considering the case $q < 1+\alpha$, hence these moments are finite if we choose $\eta$ small enough. Hence, $\{|A_T^{-1}X^*_1(T)^q|\}$ is uniformly integrable, the moments converge and from [17, Theorem 1] we have that $\tau_{X^*_1}(q) = q/(1+\alpha)$ for $q < 1+\alpha$. Since the scaling function is convex (see e.g. [18]), hence continuous, we obtain

$$\tau_{X^*_1}(q) = \frac{1}{1+\alpha}q, \quad \text{for } q \leq 1 + \alpha.$$  

- We now turn to the case $1+\alpha < q < \gamma$ in Lemma 4.4. We will show that for arbitrary $\varepsilon > 0$

$$E\left|T^{-1+\frac{\alpha}{q}}X^*_1(T)^q\right| \leq C,$$  

for some constant $C > 0$ and $T$ large enough. This implies that $\tau_{X^*_1}(q) \leq q - \alpha + \varepsilon$ and completes the proof since $\varepsilon$ is arbitrary. To show (4.32), we will use (4.27) with $A_T = T^{1-\alpha/q+\varepsilon/q}$. First, by (4.12) and (4.14), we may express the cumulant function of $X^*_1(T)$ as

$$\kappa_{A_T^{-1}X^*_1(T)}(\zeta) = \int_0^\infty \int_{-\infty}^0 \kappa_{L_1}(A_T^{-1}\zeta \xi^{-1} e^{\xi s} (1 - e^{-\xi T})) ds\xi(\xi)$$

$$+ \int_0^{\infty} \int_0^T \kappa_{L_1}(A_T^{-1}\zeta \xi^{-1} (1 - e^{-\xi(T-s)})) ds\xi(\xi).$$

Making a change of variables and writing $p(x) = \alpha\tilde{\ell}(x^{-1})x^{\alpha-1}$, with $\tilde{\ell}(t) \sim \ell(t)$ as
\[ t \to \infty, \text{ yields} \]
\[
\kappa_{A^{-1}X_1(T)}(\zeta) = \int_{-\infty}^{\infty} \int_{-\infty}^{0} \kappa_{L_1} \left( T^{\frac{q-\xi}{2}} \int_{1-e^{-x}}^{1} (1-e^{-x\alpha}) \right) dx T^{-1}\pi(T^{-1}dx) \\
+ \int_{0}^{\infty} \int_{0}^{T} \kappa_{L} \left( T^{\frac{q-\xi}{2}} \int_{1-e^{-x}}^{1} (1-e^{-x\alpha}) \right) dx T^{-1}\pi(T^{-1}dx) \\
= \int_{-\infty}^{0} \int_{-\infty}^{0} \kappa_{L_1} \left( T^{\frac{q-\xi}{2}} \int_{1-e^{-x}}^{1} (1-e^{-x\alpha}) \right) dx T^{-1}\pi(T^{-1}dx) \\
+ \int_{0}^{1} \int_{0}^{1} \kappa_{L} \left( T^{\frac{q-\xi}{2}} \int_{1-e^{-x}}^{1} (1-e^{-x\alpha}) \right) dx T^{-1}\pi(T^{-1}dx) \\
= \int_{0}^{\infty} \int_{0}^{\infty} \kappa_{L_1} \left( T^{\frac{q-\xi}{2}} \int_{1-e^{-x}}^{1} (1-e^{-x\alpha}) \right) dx T^{-1}\pi(T^{-1}dx) \\
+ \int_{0}^{1} \int_{0}^{1} \kappa_{L} \left( T^{\frac{q-\xi}{2}} \int_{1-e^{-x}}^{1} (1-e^{-x\alpha}) \right) dx T^{-1}\pi(T^{-1}dx).
\]

Take \( \delta > 0 \) such that \( q + \delta < \gamma \) and \( \delta < \frac{q \alpha}{n - \xi} \) and note that from (4.17) we have the bound
\[
|\kappa_{L_1}(\zeta)| \leq C|\zeta|^{q+\delta}, \quad \zeta \in \mathbb{R}.
\]

Hence,
\[
|\kappa_{A^{-1}X_1(T)}(\zeta)| \\
\leq C|\zeta|^{q+\delta} \int_{0}^{\infty} \int_{0}^{0} x^{\alpha-q-\delta} e^{(q+\delta)xu} (1-e^{-x})^{q+\delta} \tilde{\alpha}(T^{-1})T^{\frac{q-\xi}{2}}(q+\delta)-\alpha dx du \\
+ C|\zeta|^{q+\delta} \int_{0}^{\infty} \int_{0}^{1} x^{\alpha-q-\delta} (1-e^{-xu})^{q+\delta} \tilde{\alpha}(T^{-1})T^{\frac{q-\xi}{2}}(q+\delta)-\alpha dx du.
\]

Note that by the choice of \( \delta \), we have \( \left( \frac{q}{q} - \frac{q}{\xi} \right)(q+\delta) - \alpha < 0 \). By Potter’s bounds, for any \( \eta > 0 \) we have that \( \tilde{\alpha}(T^{-1}) \leq C_1 \tilde{\alpha}(x^{-1})T^{q\eta} \). Taking \( \eta < \alpha - \left( \frac{q}{q} - \frac{q}{\xi} \right)(q+\delta) \) yields
\[
|\kappa_{A^{-1}X_1(T)}(\zeta)| \\
\leq C_2 T^{\frac{q-\xi}{2}}(q+\delta)-\alpha+\eta|\zeta|^{q+\delta} \int_{0}^{\infty} x^{\alpha-q-1-\delta} (1-e^{-x})^{q+\delta} \tilde{\alpha}(x^{-1})dx \\
+ C_3 T^{\frac{q-\xi}{2}}(q+\delta)-\alpha+\eta|\zeta|^{q+\delta} \int_{0}^{1} x^{\alpha-q-\delta} (1-e^{-xu})^{q+\delta} \tilde{\alpha}(x^{-1})dx \\
\leq C_2 |\zeta|^{q+\delta} \int_{0}^{\infty} x^{\alpha-q-1} \tilde{\alpha}(x^{-1})dx \\
+ C_3 |\zeta|^{q+\delta} \int_{0}^{1} x^{\alpha-q-\delta} \tilde{\alpha}(x^{-1})dx \\
\leq C_2 |\zeta|^{q+\delta} + C_4 |\zeta|^{q+\delta} \int_{0}^{\infty} x^{\pi}(dx) \\
\leq C_5 |\zeta|^{q+\delta},
\]

where we have used the inequality \( x^{-1}(1-e^{-x}) \leq 1, x > 0, (2.6) \) and the fact that \( \pi \) is probability measure. This completes the derivation of the bound for \( |\kappa_{A^{-1}X_1(T)}(\zeta)| \).

Now we use (4.27) to get that
\[
E \left| T^{-1+\frac{q-\xi}{2}} X_1(T) \right|^q \leq k_q \int_{-\infty}^{\infty} (1-\exp(-2C_5|\zeta|^{q+\delta})) |\zeta|^{-q-1} d\zeta.
\]
Intermittency and infinite variance

The right hand side corresponds to the $q$-th absolute moment of $(q + \delta)$-stable random variable which is finite. Hence, (4.32) holds and this completes the proof.

In case $\gamma > 1 + \alpha$, for the moments of order $q$ in the range $(1 + \alpha, \gamma)$ we are not able to obtain the exact form of the scaling function $\tau_{X_1^*}(q)$ in Lemma 4.4. However, we provide a bound which will be enough for the proof of the main results later on. We conjecture that equality holds in (4.26). The proofs of Lemma 4.3 and Lemma 4.4 are particularly delicate because of the presence of infinite second moments.

4.2.2 The scaling function of $X_2^*$

By the decomposition (4.2), $X_2^*$ is the integrated supOU process corresponding to a characteristic quadruple $(0, 0, \mu_2, \pi)$ where $\mu_2(dx) = \mu(dx)1_{|x| \leq 1}(dx)$ and we assume $\mu_2 \not\equiv 0$. In particular, $X_2^*$ has finite variance since $\int_{|x| > 1} x^2 \mu_2(dx) < \infty$. Moreover, $\int_{|x| > 1} e^{\alpha |x|} \mu_2(dx) < \infty$ and exponential moment of $X_2^*(1)$ is finite which by [26, Theorem 7.2.1] implies that the cumulant function of $X_2^*(1)$ is analytic in the neighborhood of the origin and all moments are finite. Hence, we may use the results of [19], namely Eq. (4.9), Theorem 4.2 and Theorem 4.3 from [19]. These results are stated here in the following lemma.

**Lemma 4.5.** Suppose that Assumption 2.1 holds. Then the scaling function $\tau_{X_2^*}(q)$ of the process $X_2^*$ is as follows:

(a) If $\alpha > 1$, then

$$
\tau_{X_2^*}(q) = \begin{cases} 
\frac{1}{2}q, & 0 < q \leq q_* \\
q - \alpha, & q \geq q^* 
\end{cases}
$$

where $q_*$ is the largest even integer less than or equal to $2\alpha$ and $q^*$ is the smallest even integer greater than $2\alpha$.

(b) If $\alpha \in (0, 1)$ and $\beta < 1 + \alpha$, then

$$
\tau_{X_2^*}(q) = \begin{cases} 
\frac{1}{1+\alpha} q, & 0 < q \leq 1 + \alpha \\
q - \alpha, & q \geq 1 + \alpha 
\end{cases}
$$

(c) If $\alpha \in (0, 1)$ and $1 + \alpha < \beta < 2$, then

$$
\tau_{X_2^*}(q) = \begin{cases} 
\left(1 - \frac{\alpha}{\beta}\right) q, & 0 < q \leq \beta \\
q - \alpha, & q \geq \beta 
\end{cases}
$$

Lemma 4.5(a) and convexity of the scaling function imply that for $q_* \leq q \leq q^*$

$$
\tau_{X_2^*}(q) \leq \frac{q^* - \alpha - q_*^2}{q^* - q_*} (x - q_*) + \frac{q_*}{2}.
$$

Note also that Lemma 4.5(a) implies that $\tau_{X_2^*}(q) = q/2$ for $q \leq 2$ which will be enough for the proofs of Theorems 3.1 and 3.2 below.

In contrast with the component $X_1^*$, the scaling function of $X_2^*$ displays intermittency in any case covered by Lemma 4.5. Even in the short-range dependent scenario $\alpha > 1$, intermittency appears for higher order moments.
4.2.3 The scaling function of $X_3^+$

The process $X_3^+$ defined in (4.2) is a Gaussian process. Its scaling function is given in [19, Theorem 4.1 and 4.4]. Gaussian supOU processes do not display intermittency and their scaling function is linear over positive reals. This result is stated here in Lemma 4.6.

**Lemma 4.6.** Suppose that Assumption 2.1 holds. Then the scaling function $\tau_{X_3^+}(q)$ of the process $X_3^+$ is as follows:

(a) If $\alpha > 1$, then
$$\tau_{X_3^+}(q) = \frac{1}{2} q, \quad \forall q > 0.$$  

(b) If $\alpha \in (0, 1)$, then
$$\tau_{X_3^+}(q) = \left(1 - \frac{\alpha}{2}\right) q, \quad \forall q > 0.$$  

4.3 The scaling function of the integrated process $X^*$

To derive the scaling function of the integrated process $X^* = X_1^* + X_2^* + X_3^*$ we will use the expressions for the scaling functions of components in the decomposition (4.2) and the following proposition which shows how to compute the scaling function of a sum of independent processes.

**Proposition 4.7.** Let $Y_1 = \{Y_1(t), t \geq 0\}$ and $Y_2 = \{Y_2(t), t \geq 0\}$ be two independent processes with the scaling functions $\gamma_{Y_1}$ and $\gamma_{Y_2}$, respectively, and suppose that $EY_1(t) = EY_2(t) = 0$ for every $t \geq 0$ if the mean is finite. Suppose $q \in (0, \pi(Y_1)) \cap (0, \pi(Y_2))$ and $\gamma_{Y_1}(q)$ and $\gamma_{Y_2}(q)$ are well-defined and positive. If $q < 1$, assume additionally that $\gamma_{Y_1}(q) \neq \gamma_{Y_2}(q)$. Then the scaling function of the sum $Y_1 + Y_2 = \{Y_1(t) + Y_2(t), t \geq 0\}$, evaluated at point $q$, equals

$$\tau_{Y_1 + Y_2}(q) = \max \{\tau_{Y_1}(q), \tau_{Y_2}(q)\}.$$  

**Proof.** Suppose that $\max \{\tau_{Y_1}(q), \tau_{Y_2}(q)\} = \tau_{Y_1}(q)$. For $\varepsilon > 0$ we can take $t$ large enough so that

$$\frac{\log E|Y_1(t)|^q}{\log t} \geq \frac{\log E|Y_2(t)|^q}{\log t} - \varepsilon$$

and hence

$$E|Y_1(t)|^q \geq E|Y_2(t)|^q t^{-\varepsilon}.$$  

From the inequality

$$E|Y_1(t) + Y_2(t)|^q \leq c_q E|Y_1(t)|^q + c_q E|Y_2(t)|^q,$$  

we have that

$$\tau_{Y_1 + Y_2}(q) = \lim_{t \to \infty} \frac{\log E|Y_1(t) + Y_2(t)|^q}{\log t}$$

$$\leq \lim_{t \to \infty} \left(\frac{\log c_q}{\log t} + \frac{\log (E|Y_1(t)|^q + E|Y_2(t)|^q)}{\log t}\right)$$

$$= \lim_{t \to \infty} \frac{\log E|Y_1(t)|^q + \log \left(1 + \frac{E|Y_2(t)|^q}{E|Y_1(t)|^q}\right)}{\log t}$$

$$\leq \lim_{t \to \infty} \frac{\log E|Y_1(t)|^q + \log (1 + t^\varepsilon)}{\log t}$$

$$= \tau_{Y_1}(q) + \varepsilon,$$

where we used (4.33). Since $\varepsilon$ was arbitrary, we conclude $\tau_{Y_1 + Y_2}(q) \leq \max \{\tau_{Y_1}(q), \tau_{Y_2}(q)\}$.
We prove the reverse inequality for the \( q \geq 1 \) case first. Note that in this case \( EY_1(t) = EY_2(t) = 0 \) for every \( t \geq 0 \). For \( x \in \mathbb{R} \) we have by using Jensen’s inequality that

\[
|x|^q = |x + EY_2(t)|^q \leq E|x + Y_2(t)|^q.
\]

Letting \( F_{Y_1(t)} \) and \( F_{Y_2(t)} \) denote the distribution functions of \( Y_1(t) \) and \( Y_2(t) \), respectively, we get by independence

\[
E|Y_1(t)|^q = \int_{-\infty}^{\infty} |x|^q dF_{Y_1(t)}(x) \leq \int_{-\infty}^{\infty} E|x + Y_2(t)|^q dF_{Y_1(t)}(x)
\]

\[
= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} |y|^q dF_{Y_2(t)}(y)dF_{Y_1(t)}(x) = E|Y_1(t) + Y_2(t)|^q.
\]

From here it follows that

\[
\tau_{Y_1+Y_2}(q) \geq \tau_{Y_1}(q).
\]

Suppose now that \( q < 1 \) and let \( Y_2' = \{Y_2'(t), t \geq 0\} \) be an independent copy of the process \( Y_2 = \{Y_2(t), t \geq 0\} \), independent of \( Y_1 \). From (4.34) we have that

\[
E|Y_1(t) + Y_2(t)|^q \geq E|Y_1(t) + Y_2(t) - Y_2'(t)|^q - E|Y_2(t)|^q.
\]

(4.35)

Since \( Y_2(t) - Y_2'(t) \) is symmetric it follows that \( Y_1(t) + Y_2(t) - Y_2'(t) \equiv Y_1(t) - Y_2(t) + Y_2'(t) \). From the identity

\[
Y_1(t) = \frac{1}{2} (Y_1(t) + Y_2(t) - Y_2'(t) + Y_1(t) - Y_2(t) + Y_2'(t))
\]

we get by using (4.34) that

\[
E|Y_1(t)|^q \leq 2^{-q} \left( E|Y_1(t) + Y_2(t) - Y_2'(t)|^q + E|Y_1(t) - Y_2(t) + Y_2'(t)|^q \right)
\]

\[
= 2^{1-q} E|Y_1(t) + Y_2(t) - Y_2'(t)|^q.
\]

Returning back to (4.35) we have

\[
E|Y_1(t) + Y_2(t)|^q \geq 2^{q-1} E|Y_1(t)|^q - E|Y_2(t)|^q = E|Y_1(t)|^q \left( 2^{q-1} - \frac{E|Y_2(t)|^q}{E|Y_1(t)|^q} \right).
\]

(4.36)

We assumed that \( \tau_{Y_1}(q) \neq \tau_{Y_2}(q) \) and without loss of generality let \( \tau_{Y_1}(q) > \tau_{Y_2}(q) \). For \( \varepsilon > 0 \) small enough we can take \( t \) large enough so that

\[
\frac{\log E|Y_1(t)|^q}{\log t} \geq \frac{\log E|Y_2(t)|^q}{\log t} + \varepsilon
\]

and hence

\[
E|Y_1(t)|^q \geq E|Y_2(t)|^q t^\varepsilon.
\]

We conclude that

\[
\frac{E|Y_2(t)|^q}{E|Y_1(t)|^q} \rightarrow 0, \quad \text{as } t \rightarrow \infty.
\]

By taking logarithms in (4.36), dividing by \( \log t \) and letting \( t \rightarrow \infty \), we get

\[
\tau_{Y_1+Y_2}(q) \geq \tau_{Y_1}(q).
\]

We are now ready for the proofs of the main results.

**Proof of Theorem 3.1.** We shall combine the results of Lemmas 4.3, 4.4 and 4.5 by using Proposition 4.7.

(a) Suppose that \( \gamma < 1 + \alpha \) and split cases depending on the scaling function of \( X_2^* \).
If \( \alpha > 1 \), then from Lemma 4.5 \( \tau_{X^*}(q) = q/2 \) for \( q \in (0, 2) \). Since \( 1/\gamma > 1/2 \), we have for \( q \in (0, \gamma) \)
\[
\tau_{X^*}(q) = \max \{ \tau_{X^*}(q), \tau_{X^*_*}(q) \} = \max \left\{ \frac{1}{\gamma}q, \frac{1}{2}q \right\} = \frac{1}{\gamma}q.
\]

If \( \alpha \in (0, 1) \) and \( \beta < 1 + \alpha \), then we have for \( q \in (0, \gamma) \)
\[
\tau_{X^*}(q) = \max \{ \tau_{X^*}(q), \tau_{X^*_*}(q) \} = \max \left\{ \frac{1}{\gamma}q, \frac{1}{1 + \alpha}q \right\} = \frac{1}{\gamma}q,
\]

since \( \frac{1}{\gamma} > \frac{1}{1 + \alpha} \).

If \( \alpha \in (0, 1) \) and \( \beta > 1 + \alpha \), then for \( q \in (0, \gamma) \)
\[
\tau_{X^*}(q) = \max \{ \tau_{X^*}(q), \tau_{X^*_*}(q) \} = \max \left\{ \frac{1}{\gamma}q, \left(1 - \frac{\alpha}{\beta}\right)q \right\} = \frac{1}{\gamma}q,
\]

since \( 1 - \frac{\alpha}{\beta} < 1 + \frac{1}{\gamma - \alpha} < 1 + \frac{1}{\gamma} = \frac{1}{\gamma} \).

If \( \gamma > 1 + \alpha \) and \( \beta < 1 + \alpha \), then necessarily \( \alpha \in (0, 1) \). For \( 1 \leq q \leq 1 + \alpha \) we have by Proposition 4.7 and by Lemmas 4.4 and 4.5 that
\[
\tau_{X^*}(q) = \max \{ \tau_{X^*}(q), \tau_{X^*_*}(q) \} = \max \left\{ \frac{1}{1 + \alpha}q, \frac{1}{1 + \alpha}q \right\} = \frac{1}{1 + \alpha}q. \quad (4.37)
\]

Since \( \tau_{X^*}(q) = \tau_{X^*_*}(q) \) we cannot use Proposition 4.7 for \( q < 1 \), but from (4.37), \( \tau_{X^*}(0) = 0 \) and the fact that the scaling function is always convex, we conclude using [17, Lemma 2] that \( \tau_{X^*}(q) = \frac{1}{1 + \alpha}q \) for \( q < 1 \) also.

For \( 1 + \alpha < q < \gamma \) we have \( \tau_{X^*}(q) = \max \{ \tau_{X^*}(q), \tau_{X^*_*}(q) \} = \max \left\{ \frac{1}{1 + \alpha}q, q - \alpha \right\} = q - \alpha. \)

If \( \gamma > 1 + \alpha, \beta > 1 + \alpha \) and \( \beta \leq \gamma \), we have
\[
\tau_{X^*}(q) = \begin{cases} 
\max \left\{ \frac{1}{1 + \alpha}q, \left(1 - \frac{\beta}{\gamma}\right)q \right\}, & 0 < q \leq 1 + \alpha, \\
\max \left\{ \tau_{X^*}(q), \left(1 - \frac{\beta}{\gamma}\right)q \right\}, & 1 + \alpha < q \leq \beta, \\
\max \left\{ \tau_{X^*}(q), q - \alpha \right\}, & \beta < q < \gamma.
\end{cases}
\]

For the case \( q \leq 1 + \alpha \), note that because \( \beta > 1 + \alpha \) we have \( 1 - \frac{\beta}{\gamma} > 1 - \frac{\alpha}{\gamma} = \frac{1}{1 + \alpha} \).

In Lemma 4.4 we showed that \( \tau_{X^*}(q) \leq q - \alpha \) for \( 1 + \alpha < q < \gamma \) and for \( q \leq \beta \) we have \( q - \frac{\alpha}{\beta}q \geq q - \alpha \). Hence we obtain
\[
\tau_{X^*}(q) = \begin{cases} 
\left(1 - \frac{\alpha}{\beta}\right)q, & 0 < q \leq 1 + \alpha, \\
\left(1 - \frac{\beta}{\gamma}\right)q, & 1 + \alpha < q \leq \beta, \\
q - \alpha, & \beta < q < \gamma.
\end{cases}
\]

If \( \gamma > 1 + \alpha, \beta > 1 + \alpha \) and \( \beta > \gamma \), then by using the same arguments as in the previous case we get
\[
\tau_{X^*}(q) = \begin{cases} 
\max \left\{ \frac{1}{1 + \alpha}q, \left(1 - \frac{\beta}{\gamma}\right)q \right\}, & 0 < q \leq 1 + \alpha, \\
\max \left\{ \tau_{X^*}(q), \left(1 - \frac{\beta}{\gamma}\right)q \right\}, & 1 + \alpha < q < \gamma, \quad = \left(1 - \frac{\alpha}{\beta}\right)q, & 0 < q < \gamma. \quad \square
\end{cases}
\]

One may follow the proof of Theorem 3.1 from Figure 2. Each subfigure shows the scaling function of \( X^* \) in blue and the scaling function of \( X^*_* \) in red. Following Proposition 4.7, the scaling function of the integrated process \( X^* \) (thick green) is obtained by taking the maximum of these two functions.
Intermittency and infinite variance

\begin{align*}
\tau_{X^*}(q) &= \max \left\{ \tau_{X_1^*}(q), \tau_{X_2^*}(q) \right\}.
\end{align*}

\textbf{Proof of Theorem 3.2.} We will use the results of Theorem 3.1 and Lemma 4.6 and combine them using Proposition 4.7 so that

\begin{align*}
\tau_{X^*}(q) &= \max \left\{ \tau_{X_1^*}(q) + \tau_{X_2^*}(q) \right\}.
\end{align*}

Figure 2: The scaling functions of $X^*$ when $b = 0$ (no Gaussian component). Each plot shows the scaling functions $\tau_{X_1^*}$ (blue), $\tau_{X_2^*}$ (red) and $\tau_{X^*}$ (thick green). Dashed parts of the plots denote the upper bounds. The vertical thick dotted line denotes the position of $\gamma$, beyond which the moments of $X_1^*$ and $X^*$ are infinite.
Intermittency and infinite variance

\[ \gamma_1^{\alpha} + \gamma_q^{\alpha} \]

\[ \tau_{X^*}(q) = \max \left\{ \frac{1}{\gamma q}, \frac{1}{2^{q}} \right\} = \frac{1}{\gamma q}. \]

If \( \alpha \in (0, 1) \) and \( \gamma < \frac{2}{2-\alpha} < 1 + \alpha \) and \( \beta < 1 + \alpha \), then

\[ \tau_{X^*}(q) = \max \left\{ \frac{1}{\gamma q}, \left( 1 - \frac{\alpha}{2} \right) q \right\} = \frac{1}{\gamma q}, \]

since \( 1/\gamma > 1 - \alpha/2 \iff \gamma < 2/(2 - \alpha) \).

(b) Suppose now that \( \alpha \in (0, 1) \) and \( \gamma > \frac{2}{2-\alpha} \).

- If \( \frac{2}{2-\alpha} < \gamma < 1 + \alpha \), then

\[ \tau_{X^*}(q) = \max \left\{ \frac{1}{\gamma q}, \left( 1 - \frac{\alpha}{2} \right) q \right\} = \left( 1 - \frac{\alpha}{2} \right) q, \]

since \( 1/\gamma < 1 - \alpha/2 \).
Intermittency and infinite variance

(a) $\alpha \in (0, 1)$, $\frac{2}{2-\alpha} < \gamma < 1 + \alpha$ and $\beta < 1 + \alpha$

(b) $\alpha \in (0, 1)$, $\frac{2}{2-\alpha} < \gamma < 1 + \alpha$ and $\beta > 1 + \alpha$

(c) $\beta < 1 + \alpha < \gamma$ (implies $\alpha \in (0, 1)$ and $\gamma > \frac{2}{2-\alpha}$)

(d) $1 + \alpha < \beta \leq \gamma$ (implies $\alpha \in (0, 1)$ and $\gamma > \frac{2}{2-\alpha}$)

(e) $1 + \alpha < \gamma < \beta$ (implies $\alpha \in (0, 1)$ and $\gamma > \frac{2}{2-\alpha}$)

Figure 4: The scaling functions of $X^*$ when $b \neq 0$: case (b) of Theorem 3.2. Each plot shows the scaling functions $\tau_{X^*_1}$ (blue), $\tau_{X^*_2}$ (red), $\tau_{X^*_3}$ (purple) and $\tau_{X^*}$ (thick green). Dashed part of the plot denotes the upper bound. The vertical thick dotted line denotes the position of $\gamma$, beyond which the moments of $X^*_1$ and $X^*$ are infinite.
Intermittency and infinite variance

- If $\gamma > 1 + \alpha$ and $\beta < 1 + \alpha$, then we have
  \[ \tau_{X^*}(q) = \begin{cases} 
  \max \left\{ \frac{1}{1+\alpha} q, (1 - \frac{\alpha}{2}) q \right\}, & 0 < q \leq 1 + \alpha, \\
  \max \left\{ q - \alpha, (1 - \frac{\alpha}{2}) q \right\}, & 1 + \alpha < q < \gamma.
  \end{cases} \]

  Now $\alpha < 1$ implies $\frac{1}{1+\alpha} = 1 - \frac{\alpha}{1+\alpha} < 1 - \frac{\alpha}{2}$ and for $q < 2$ we have $q - \frac{\alpha}{2} q > q - \alpha$. Hence,
  \[ \tau_{X^*}(q) = \left(1 - \frac{\alpha}{2}\right) q, \quad 0 < q < \gamma. \]

- If $\gamma > 1 + \alpha$, $1 + \alpha < \beta$ and $\beta \leq \gamma$, then
  \[ \tau_{X^*}(q) = \begin{cases} 
  \max \left\{ (1 - \frac{\alpha}{\beta}) q, (1 - \frac{\alpha}{2}) q \right\}, & 0 < q \leq \beta, \\
  \max \left\{ q - \alpha, (1 - \frac{\alpha}{2}) q \right\}, & \beta < q < \gamma.
  \end{cases} \]

  since $1 - \frac{\alpha}{\beta} < 1 - \frac{\alpha}{2}$ and by the same argument as in the previous case.

- The same argument applies to case $\gamma > 1 + \alpha$, $1 + \alpha < \beta$ and $\beta > \gamma$. \[ \square \]

Figures 3 and 4 illustrate the proof of Theorem 3.2. The scaling functions $\tau_{X^*_1}$, $\tau_{X^*_2}$, and $\tau_{X^*_3}$ of each component are shown on each plot in red, blue and purple, respectively, while their maximum is denoted by the thick green line. Figure 3 is related to the case (a) of Theorem 3.2 and Figure 4 to the case (b) of Theorem 3.2. The figures are split based on different forms of the scaling functions of the three components $X^*_1$, $X^*_2$ and $X^*_3$.
