Women in Statistics in Academe: Mentors Matter

Deborah Nolan

Abstract. Federal and state agencies, private industry and professional societies are developing programs to encourage women to enter the education “pipeline” for careers in science and technology. To reverse female students’ underrepresentation in science and to retain incoming women in these fields, especially those entering academia, requires the active support of women and men faculty as mentors. The focus of the present manuscript addresses this issue. Here, we give a profile of women in statistics and, more broadly, in the sciences, and we outline the elements of a good mentor. Statistics are presented in support of our argument, but case studies form the basis for the recommendations.

Key words and phrases: Mentor, role model, women in science, campus climate.

INTRODUCTION

Female scientists in academia are few in number. Women drop out of the education pipeline before arriving at the professional pool of individuals with science doctorates. Those women who do obtain doctorates in science and then enter academia may not find a warm, welcome environment. Hornig (1979) asks us to consider whether some simple adjustments in the training of scientists might not make these disciplines more attractive and more rewarding for women. The position advocated here is that change will occur when the men and women of the academy take part in improving the academic climate. Perhaps more than any institutionally sponsored program, the individual efforts of scientists as mentors are essential for increasing the participation of women in the sciences.

The benefits of mentorship are difficult to measure quantitatively (Merriam, 1983; Merriam, Thomas and Zeph, 1987), but in academic settings it is commonly accepted that having a mentor is a decided advantage at the start of a career (Simeone, 1987; Hall and Sandler, 1983). My own experiences in the academic world support this assumption; they also support the belief that women in the sciences may need particular assistance for finding mentors (Miller, 1976; Rowe, 1981). To this end, identified here are the elements of mentorship that enable a new scientist to come into her own. These elements provide a relationship context from which junior researchers can develop professionally and participate fully in the scientific community. Ideally, this scientist can then pass on the benefits she received from good mentoring as a role model for younger women. Also discussed are ways senior researchers and administrators can foster a work environment in which mentoring is encouraged. The ideas put forth here are grounded in my experiences as a new, female statistician in academe. I have also taken note of the experiences of female scientists at other universities and of the literature on mentoring. It is my hope that the suggestions articulated here will be adopted by the men and women in academia to the benefit of women in science.

BACKGROUND

The following statistics on women’s participation in the scientific community are presented to provide a context for a discussion of mentoring. These data include figures on the representation of women in the sciences and the loss of women from the science education pipeline.

First an historical perspective on women in statistics is summarized from Rossiter (1982). In the early part of this century in the United States, statistics (along with botany, microbiology and clinical psychology) was a “feminine” science. Employment figures for the federal government in the 1930s show that, next to nutrition, statistics was the most highly feminized scientific field. Ironically, at the time, only 10% of the federally employed statisticians were women.

This relatively large concentration of women in a scientific field is attributable to the convergence of World War I and advances in the area of survey sampling. From 1916 to 1919 the federal government hired 250,000 clerks and stenographers, and as the war took men out of the work force, most of those hired were

Deborah Nolan is Professor, Department of Statistics, University of California, 367 Evans Hall, Berkeley, California 94720.
women. With innovations in survey sampling (Kruskal and Mosteller, 1980), statistics became a growing field in the government in the twenties and thirties. It grew out of the existing social services, and it was from the clerical positions within these services that women were able to become statisticians.\(^1\) In 1938 the Bureau of Labor Statistics reported that the federal government employed 855 mathematicians and statisticians, and 86 of them were women.

Fifty years later the situation shows little improvement. The National Science Foundation estimates that in 1989 the federal government employed 281 Ph.D. statisticians; approximately 11% were women. In the academic world the situation is much the same. According to the 1938 edition of American Men of Science, women comprised nearly 10% of the mathematicians in the academy (40% of whom were employed by women's colleges). In 1989, almost 2,000 Ph.D. statisticians were employed in educational institutions in the United States, and women's participation was also about 11%.\(^2\)

Women's numbers decrease relative to men's as they proceed through the education pipeline to a doctorate in science. For example, according to the annual reports of the Committee on the Status of Women in Economics (1985, 1988), in the late 1980's, women were awarded roughly one-third of the B.A.'s and one-sixth of the doctorates in Economics in the United States. A similar example, on a smaller scale, is seen at the University of California at Berkeley. In the 5-year period from 1986 to 1990, women were awarded 46 of the 100 B.A.'s and 18 of the 97 Ph.D.'s in Statistics. In this same period, women received 38% of the 1,309 B.A.'s and 25 of the 99 Ph.D.'s awarded in Economics. (These statistics were provided by the Office of Institutional Resources, University of California at Berkeley.)

**CURRENT CLIMATE**

The numbers cited above serve as a background for discussing the challenges facing academic women in science. In interviews with 20 academic women at a large northeastern university (Simeone, 1987), one faculty woman describes the problem:

I think it's the opportunity that differs now, because so much of what goes on in academics is subjective. So much is access to discussing a project over a drink and then going on to work on a paper together, and that kind of camaraderie that generates research interest and brings an entering assistant professor into understanding research and active participation is often closed to women . . . And then there's the fact that a lot of men just don't feel as comfortable talking over research with a woman as with a man, and these are the same people who, I think, would treat a male and a female with the same record equitably in terms of promotion and in terms of giving them a job. It's just that once they're here—they don't get the same access. (p. 86)

Many of my female junior colleagues at other institutions have expressed similar sentiments. Their experiences include not receiving invitations to dine, not having the opportunity to play sports and not being included in impromptu lunches with senior colleagues. They also speak of annoying, though perhaps less serious, instances of being mistaken by visiting colleagues for a temporary appointee, or for a secretary when organizing after-seminar dinners. One recent example occurred when a senior colleague and I interviewed a prospective graduate student. At the conclusion of the meeting the prospective student thanked both of us for our time, addressing me by my first name and my colleague by his title and last name, and offering to shake my colleague's hand but not mine. Sandler and Hall (1986) relate many more anecdotal examples of these differences, and go so far as to call the campus climate chilly for women graduate students and faculty.

It was not until I became an assistant professor that I discovered how such treatment impedes creativity, productivity and day-to-day survival. These experiences lead to isolation, adding to a sense of inadequacy. This in turn makes it increasingly difficult to participate in the department, and can progressively separate the young female researcher from her senior colleagues both within her department and the larger scientific community. The importance of mentoring is under-

---

\(^1\) In 1921, the Bureau of Vocational Information of New York City published "Statistical Work: A Study of Opportunity for Woman." The publication presented evidence for the new jobs opportunities for women as statisticians. There it was said that in 1918 19 women took the Civil Service test for "statistician," all 19 passed the test and two were hired. One year later, 49 women took this exam, again all passed and this time 12 were hired. Also, that year 639 women took the Civil Service test for "statistical clerk." 245 passed and 91 were hired.

\(^2\) Since 1973, the National Science Foundation (NSF) has conducted a biennial survey of the population of individuals in the United States with doctorates in science and engineering. From the 1989 study, NSF estimates the number employed with doctorates in science and engineering to be 448,643. Of these 17.2% are women. Looking at the mathematical sciences, women's representation drops to slightly less than 10%, and for statistics alone, NSF estimates the number of employed statisticians to be 2,744 of which 320 (11.7%) are female. (These figures do not include biostatisticians, econometricians or social statisticians.) Additionally, approximately 60% of the female and 75% of the male Ph.D. statisticians are employed in educational institutions. Standard errors for these percentages are roughly 1.8%.
scored by the following review of studies that examine
the apparent differences between men and women in
self-esteem and in perceptions of the academic climate.

A study conducted by the Great Lakes College Asso-
ciation (GLCA) in 1984 surveyed all women faculty in
11 of the 12 associated colleges. Approximately half
(172) the women in the GLCA completed the survey,
and of these over three-fourths agreed with the state-
ment that male faculty regard and treat male colle-
gues differently than female colleagues. In a 1984
survey of American graduate students in science, en-
gineering and medicine at Stanford University (Zappert
and Stansbury, 1984), all women and an equal number
of randomly selected men in these fields were ques-
tioned. Again approximately half (328 women, 299
men) of those surveyed responded. A comparison of
those male and female students responding “always”
or “often” to the following statements is illustrative of
gender differences in self-esteem. How often do you
trust your own judgement (92% of males, 80% of fe-
nal sexes); fear speaking will reveal inadequacy (9% of
males, 33% of females); question if you can make it in
your field (9% of males, 24% of females); feel able to
negotiate for needs (62% of males, 42% of females).
Another study (Mura, 1987) surveyed all undergradu-
ates in math courses at five Canadian universities;
approximately 90%, or 1,270, responded. It was found
that when asked to predict their course grade at the
beginning of the course, 51% of the females overesti-

A GOOD MENTOR

In academia it is considered important to have men-
toring at the start of a career (Simeone, 1987) and
access to support networks at review time (Menges
and Exum, 1983). However there are few quantitative
studies measuring the impact of a mentor on a career,
especially for faculty mentoring faculty (Merriam,
Thomas and Zeph, 1987). The most extensive literature
on mentoring is about the definition of mentor (Speizer,
1981; Fisher, 1988; Hall and Sandler, 1983). In fact,
two empirical studies have recently attempted to use
factor analysis to describe the multifaceted structure
of the mentor relationship (Wilde and Schau, 1991;
Sands, Parson and Duane, 1991). [Also, Hall and San-
der (1983) provide a guidebook for those in search of
a mentor, including tips to both potential mentors and
proteges and descriptions of various types of mentors
such as paper mentors, peer pals, guides and sponsors.]
The elements for successful mentorship need not be
gender specific. Men and women alike can benefit from
a mentor, and although the ideas put forward are drawn
from my experiences as a woman in statistics, they
should be applicable to all junior academicians. In
the Parson, Sands and Duane (1991) study of faculty
mentoring faculty a large majority of those surveyed
(87% of the women and 67% of the men) believed that
it would be beneficial to have had a mentor. Perhaps
women seem to need more support and encouragement
than men because the implicit support men receive is
not recognized as mentoring (Miller, 1976), or it may
be that women expect a different dynamic in the men-
torship (Berg and Ferber, 1983).

The goal of a mentoring relationship is to provide an
environment in which the mentee develops into an
independent researcher, taking with her the support of
the mentor yet knowing the work she accomplished is
her own. Altogether, the mentorship has the potential
to provide the mentee with a good foundation for doing
distinguished work if it (i) draws attention to the men-
tee's strengths, using them as a foundation for develop-
ment; (ii) permits differences between the mentor and
mentee, which allow the mentee to maintain a sense of
herself and her work; (iii) offers understanding of the
difficulties the mentee faces (this is not an excuse for
lack of performance) and (iv) makes it safe to make
mistakes and so develop both intellectual maturity and
self-confidence.

These items characterize the dynamics of good men-
toring, not concrete tasks for the mentor or protege.
When present they support and help convey the men-
tor's belief in the mentee. If all goes well, the mentee
can internalize this belief, move away from the mentor
to develop peer relationships and, later, draw on the
self-confidence gained from these relationships to men-
tor others.

Recently, the American Astronomical Society (AAS)
conducted a survey of its membership (Boyce, 1991). In
this 1990 study, respondents were asked if they
had witnessed or, in the case of women, experienced
discrimination against women in the form of general
social treatment. Half of the women said they had
witnessed or experienced such discrimination, whereas
only 15% of the men said they had witnessed such
discrimination. In another recent study, 100 men and
100 women at each of the assistant, associate and full
professor ranks were surveyed at a large midwestern
public university (Parson, Sands and Duane, 1991). It
was found that 59% of the women, as compared to 3%
of the men, felt their work was underestimated because
of their sex.

Finally, others examine the psychological challenges
(Moulton, 1979; Harrison, 1991; Henrion, 1991) con-
fronting women in science and the exclusion of
academic women from collegial networks (Clark and
reviews quantitative performance comparisons of aca-
demic men and women, and Fennema and Peterson
(1985) review studies on gender differences in science.
EXAMPLES

When first starting as an assistant professor of statistics, I was fortunate to have had a thesis advisor who was a good mentor. Yet, as in Hewitt (1979), continued mentoring after entering academia was important. I found mentors in settings other than the typical advisor/student role, and became aware of the elements of mentorship that promote professional development. In the four examples below, I hope to evoke the process of mentoring described above as it evolved within my own experience and furthered my professional development.

1. My thesis advisor exemplifies many aspects of the mentoring process that enable women to pursue their own creative scientific work. Our meetings typically had me at the blackboard presenting my latest results. We reviewed my work together. I was able to show him my accomplishments and at the same time he raised questions, showed me alternatives and pointed out mistakes. Other times, he had the chalk and showed me something that he was working on currently. Then I was able to see how he worked and how he made mistakes, and most importantly I felt included in a larger research endeavor. He was accessible. He talked to me. A quintessential example of his mentoring occurred when I was on the job interview circuit. My advisor received a phone call from the search committee of a university interested in hiring me. He was asked about my potential, if I was tenure material. His response indicated that he believed in me and my work, something I had already learned via his mentoring style. He said, "Yes, if you talk to her [about research]."

2. As an assistant professor, I participated in a workshop on teaching. The workshop was organized so that each participant presented segments of prepared lectures to the other participants. Feedback from the organizer and fellow workshop attendees was an important aspect of the program. I found it very successful in large part because of the constructive manner in which the organizer channeled our feedback to each other. She had us look for the strengths in the presentations, because she said if we know our strengths, we can most effectively build on them to become strong lecturers. It was notable how each participant had quite different strengths, and it became clear that each could have successful, but different, lecturing styles. For example, one female assistant professor in the workshop had a very informal speaking style, which she viewed as a hindrance to getting respect from students. The coordinator showed her, and us, how a few changes in body motion could convey confidence, yet keep intact her informal style that was open and welcoming to students.

3. After a couple of years in the university, contact with my advisor-mentor had lessened, yet I was still new to the statistical community. An associate professor at another institution welcomed me into the research community and provided a vital network of communication. We first met when I was interviewing for a job at his university. Two years later he attended a presentation I gave at a professional meeting and saw that my current research interests overlapped with his. In conversation after the talk he supplied some background information for this new area of interest of mine; he also told me of his current research problems, and inquired about the results I had just presented. Over the next 2 years we met and compared notes at statistical meetings, and between meetings we exchanged preprints, references and open problems via electronic mail. His generosity in sharing his research interests and his respect for my work added up to a much-appreciated invitation to a broader statistical community.

4. Most recently, a young visiting professor and I discovered we shared a concern over the difficulty that we had in talking with colleagues about our work. Too often the conversation drifted to easier topics such as pleasantries about family or administrative issues in the department. We thought that if we had this concern then so must other women in our field, especially female graduate students. We organized biweekly luncheons with small groups of women graduate students that had advanced to candidacy. The luncheon conversation was restricted to research. We took turns sharing our latest developments. The students, my colleague and I enjoyed these lunches, because we were part of a community of intelligent hard-working women that were serious about their careers as statisticians. The atmosphere was informal; no advisor was present; there was room to make mistakes. Most found that discussing their work helped them focus on it in a different way. They had to make it their own, not an assigned project of their advisor's. This brought them to a better understanding of the nature of their work. The basic questions asked of them helped them to put their work in a broader framework and to realize that they already were experts in their subfield.

THE INSTITUTION

Senior researchers and administrators have a crucial role to play in the advancement of women in the scientific community, for they are responsible for fostering a productive work environment for all faculty. Three examples show ways in which this can be accomplished. The first is based on an essay by Rowe (1981) that outlines how to build institutional devices that help junior researchers find mentors and that help senior researchers become more active in the professional development of their junior colleagues. The sec-
ond is a performance evaluation program in a statistics department, and the third example is a volunteer mentor program sponsored by a professional society.

Such programs and policies should be open to all junior people. Both men and women can benefit from mentorship and an inclusive policy legitimizes the process of mentoring which will, in the long run, benefit the entire academic community.

1. Rowe (1981) outlines five elements of a framework for professional development of students, faculty and administrators at the university. They are leadership by top management in encouraging senior people to be mentors; constructive women’s networks; close communication between top management and these networks; workshops and guidelines to teach junior people how to seek mentors; and performance evaluation programs that encourage senior people to sponsor junior people. Rowe argues that a required program with assigned mentors may be useful in the short term, but it is most important to make mentoring a volunteer activity of the institution.

2. The statistics department at Ohio State University (Leurgans, 1991) has in place the type of performance evaluation program advocated by Rowe. Two senior faculty aid junior faculty in preparing their cases for annual review. They meet regularly with the assistant professors, provide frank feedback on their progress and advise them on how to prepare their case. They also present the prepared case to the department at review time. This program encourages senior faculty to act proactively on behalf of the junior faculty, and it encourages junior faculty to seek advice and sponsorship from their senior colleagues.

3. A professional society for sociologists designed a volunteer mentor program to match junior researchers looking for assistance on a project with more experienced researchers (volunteers) in their field (Spade, 1991). The mentorship is limited to 1 year and a specific goal, such as the preparation of a paper for publication. In addition to providing specific feedback on the project, the mentor is encouraged to help the mentee place his or her work in the larger context of the mentee’s career development. The mentee is encouraged to participate in professional society meetings. An evaluation of the first year of the program showed that most participants were satisfied overall with the program (92% of the mentors and 63% of the mentees).

CONCLUSIONS

Mentoring can enhance the professional development of junior researchers. It can change the academic climate, making a scientific career more rewarding for women. From the examples presented, it is clear that mentoring need not be limited to the student/advisor relation. Mentors can be found in peers and in group situations. Yet these examples all have common elements that enable junior researchers to internalize a sense of self-worth, and so contribute to their field. With the aid of good mentoring, the scientist develops in a progression much as described in the examples. Initially, the mentor provides a protective environment within which the young scientist builds self-confidence. Then she can grow into her own scientific identity as a researcher and teacher, and finally come full circle as a mentor and role model for others.

The elements of successful mentoring need to be brought to the attention of new scientists. Senior researchers and administrators need to take responsibility in fostering an academic community that encourages mentoring. The active participation of senior scientists as mentors can dramatically change female junior researchers’ reception in the scientific community and, I think, can lead to increased participation of women in the sciences.

ACKNOWLEDGMENTS

An earlier draft of this paper was presented in the Committee-on-Women-in-Statistics session at the 1991 annual joint meeting of the American Statistical Association and the Institute of Mathematical Statistics. A. Bajamonde and A. Owens helped collect data and references. D. Glaser and B. Waterman supplied many insightful comments on earlier drafts of the manuscript. Two anonymous referees provided valuable comments that led to a more comprehensive paper. The author was supported in part by NSF Grant DMS-90-01710 and the 1990 Prytanean faculty award, Prytanean Society at the University of California at Berkeley.
