ON THE DEGREE OF IDEAL MEMBERSHIP PROOFS
FROM UNIFORM FAMILIES OF POLYNOMIALS
OVER A FINITE FIELD

JAN KRAJIČEK

Abstract. Let \( f_0, f_1, \ldots, f_k \) be \( n \)-variable polynomials over a finite prime field \( \mathbb{F}_p \). A proof of the ideal membership \( f_0 \in \langle f_1, \ldots, f_k \rangle \) in polynomial calculus is a sequence of polynomials \( h_1, \ldots, h_t \) such that \( h_t = f_0 \), and such that every \( h_i \) is either an \( f_j \), \( j \geq 1 \), or obtained from \( h_1, \ldots, h_{i-1} \) by one of the two inference rules: \( g_1 \) and \( g_2 \) entail any \( \mathbb{F}_p \)-linear combination of \( g_1, g_2 \), and \( g \) entails \( g \cdot g' \), for any polynomial \( g' \). The degree of the proof is the maximum degree of the \( h_i \)'s.

We give a condition on families \( \{ f_{N,0}, \ldots, f_{N,k_N} \} \) of \( n_{<\omega} \)-variable polynomials of bounded degree implying that the minimum degree of polynomial calculus proofs of \( f_{N,0} \) from \( f_{N,1}, \ldots, f_{N,k_N} \) cannot be bounded by an independent constant and, in fact, is \( \Omega(\log(\log(N))) \). In particular, we obtain an \( \Omega(\log(\log(N))) \) lower bound for the degrees of proofs of 1 (so called refutations) of the \( (N,m) \)-system (defined in [4]) formalizing a modular counting principle (where \( m \) is fixed and not divisible by \( p \), and the parameter \( N \) is not divisible by \( m \)), and a similar lower bound for refutations of systems encoding that \( N \) is composite (whenever \( N \) is a prime). No bounds were previously known for these systems. The same method yields \( \Omega(\log(N)) \) lower bounds for the degree of coefficient polynomials in Nullstellensatz proofs.

The method is based on a new result about a uniform way of generating all submoduli of tabloid moduli.

0. Introduction

We are concerned here with algebraic proof complexity and we shall use the combinatorics of the representation theory of symmetric groups (in particular, Young tableaux) to obtain new degree lower bounds for Nullstellensatz proofs.

and for polynomial calculus proofs. The application requires a new result
describing a uniform combinatorial way of generating all submoduli of tabloid
moduli. The connection between the fields is achieved by identifying certain
polynomial rings with permutation moduli. I shall discuss first the background
for proof complexity and then the combinatorics of Young tableaux used.

Algebraic proof complexity studies time complexity of non-deterministic
algorithms accepting exactly systems of polynomial equations over a fixed
field that are not solvable in that field (or some specified extension). In our
case the field will be a finite prime field, so the encoding of the system for
algorithms is straightforward.

Proof complexity in a broad sense, as I understand it, studies time com-
plexity of non-deterministic algorithms accepting a set \( L \) of finite objects of
certain type (natural numbers, polynomials, graphs, formulas, etc.). A non-
deterministic acceptor \( A \) of \( L \) is called a proof system for \( L \), a computation
accepting \( y \) is an \( A \)-proof of “\( y \in L \)”. The main goal of proof complexity is to
exhibit an explicit \( L \) for which there is no proof system running in polynomial
time. The qualification \textit{explicit} means that \( L \) should belong to some com-
putational complexity class \( X \) such as, for example, \( \text{coNP} \), polynomial time
hierarchy, or polynomial space. As the existence of a proof system running
in polynomial time just means that \( L \in \text{NP} \), proof complexity aims in effect
at showing that \( X \not\subseteq \text{NP} \). For example, whether \( \text{coNP} \subseteq \text{NP} \) is a major open
problem in complexity theory and logic.

The name \textit{proof complexity} for this area comes from its most important and
most developed part when \( L \) is the set of propositional tautologies \( \text{TAUT} \) (this
part of proof complexity is called propositional proof complexity), cf. [9]. Log-
ical calculi for proving propositional tautologies that are sound and complete
are, in particular, non-deterministic acceptors of \( \text{TAUT} \). A standard conjecture
that \( \text{NP} \neq \text{coNP} \) thus implies that none of these calculi admit polynomial
size proofs of all tautologies. However, it is a challenge and a fundamental
open problem of logic (cf. [17]) to prove unconditional lower bounds for ordi-
nary Hilbert-style propositional calculi that one can find in logic text-books.
Such bounds would also have concrete corollaries for bounded arithmetic in
terms of consistency of various open complexity-theoretic conjectures, cf. [15].
These open problems about bounded arithmetic are the most important open
questions about the logic of first-order theories of arithmetic.

Despite some remarkable achievements no non-trivial lower bounds for the
usual calculus based on a finite number of axiom schemes and on modus
ponens are known.

In previous research it turned out that some open proof complexity ques-
tions about usual propositional calculi working with boolean connectives can
be reduced to questions about degree lower bounds in various ideal mem-
bership proof systems. In fact, boolean connectives can be represented by
polynomials (with 0 and 1 representing the truth values) and thus polynomial
rings are as good an environment for propositional logic as is boolean logic itself. We shall not repeat the reductions here and instead concentrate on “algebraic” proof systems from the beginning. The reader is encouraged to consult [4, 6].

There are two main algebraic proof systems studied at present time. One system is the Nullstellensatz proof system NS, where a proof of the ideal membership $f_0 \in \langle f_1, \ldots, f_k \rangle$ (we will say just “a proof of $f_0$ from $f_1, \ldots, f_k$”), with $f_i \in F[\overline{x}]$, is a sequence $g_1, \ldots, g_k \in F[\overline{x}]$ such that

$$g_1 f_1 + \cdots + g_k f_k = f_0$$

By Hilbert’s Nullstellensatz, a proof of unsolvability of $f_1 = 0, \ldots, f_k = 0$ in the algebraic closure $\overline{F}$ of $F$ is a proof of 1 from $f_1, \ldots, f_k$. This is also called a refutation of $f_1, \ldots, f_k$.

Note that unsolvability of polynomial systems over $F_p$ (in $F_p$) is a coNP-complete language and hence the complexity of proof systems for it are as important as for tautologies.

Another proof system is polynomial calculus\(^1\). A polynomial calculus proof (PS-proof) of $f_0$ from $f_1, \ldots, f_k$ is a sequence of polynomials $h_1, \ldots, h_t$ such that $h_t = f_0$, and such that every $h_i$ is either an $f_j$, $j \geq 1$, or obtained from $h_1, \ldots, h_{i-1}$ by one of the two inference rules:

1. Addition rule: $g_1$ and $g_2$ entail any $F_p$–linear combination of $g_1, g_2$.
2. Multiplication rule: $g$ entails $g \cdot g'$, for any polynomial $g'$.

The degree of the NS–proof is the maximum degree of $g_i$'s, and the degree of the PC–proof is the maximum degree of $h_i$’s. Our goal is to prove lower bounds on the degree of proofs.

We shall study the case when the underlying field is $F_p$ and when we are interested in solvability in $F_p$ rather than in $\overline{F}_p$. This is easily achieved by including equations $x^p - x = 0$, for all variables $x$, among the starting polynomials.

The degree of NS–proofs is obviously related to the so called effective Nullstellensatz of Brownawell [5] and Kollár [14]. However, their results are proved for algebraically closed fields and the methods yield nothing for the case of bounds over finite fields. The first non-trivial lower bounds for $F_p$ were proved in [4, 6]; see those papers for a more detailed discussion of this connection.

We shall consider dense representation of polynomials. A polynomial $f$ with variables $x_1, \ldots, x_n$ and of degree $d$ is represented by a list of coefficients (in $F_p$) of all monomials of degree up to $d$, even if these are zero. The list has length proportional to $n^d$; hence superpolynomial lower bounds on size correspond to non-constant lower bounds on the degree.\(^2\)

\(^1\)This was first formally considered as a proof system in [8].

\(^2\)I remark that some of the lower bounds, most notably for the $(N,m)$–systems, actually hold also for the size of the sparse representation.
Other algebraic systems studied include various extensions of NS (see [4, 6]), and the system $F(MOD_p)$ combining algebraic and propositional reasoning (see [15, Section 12.6]).

NS–proofs are particular PC–proofs (first derive by the multiplication rule all $g_i f_i$’s and then sum them up using the addition rule) and strong lower bounds are known for them, cf. [6]. PC is a natural “depth 1” subsystem of $F(MOD_p)$. Recently a lower bound for PC was proved [21]. No lower bounds are known even for constant-depth $F(MOD_p)$, except for a weak fragment (cf. [16]).

Although we put the emphasis on proof complexity, the technical heart of our paper is a new way of generating submoduli of certain permutation moduli. It can be described briefly as follows. Let $\lambda = (\lambda_1, \ldots, \lambda_k)$, $\lambda_1 + \cdots + \lambda_k = N$, be a partition of a natural number $N$ into integers. A decomposition $X_1 \cup \cdots \cup X_k = \{0, \ldots, N - 1\}$ of $N$ into disjoint sets of size $|X_i| = \lambda_i$ is called a $\lambda$–tabloid. The tabloid module $M^\lambda$ over a field $F$ is the $F$–vector space whose basis is the set of $\lambda$–tabloids. The symmetric group $\text{Sym}(N)$ acts on $\lambda$–tabloids, and hence on elements of $M^\lambda$, and $M^\lambda$ is an $F[\text{Sym}(N)]$–module, where $F[\text{Sym}(N)]$ is the appropriate group-algebra.

We give a combinatorial/logical description of all submoduli of $M^\lambda$, depending only on $\sum_{i \geq 2} \lambda_i$ but not on $N$ (Theorem 3.3). This is based on analyzing uniformity (definability) of various combinatorial manipulations with Young tableaux and Specht moduli, as used in James’ characteristic-free representation theory of the symmetric group [13]. The connection between algebraic proof complexity and combinatorics of tabloid moduli is achieved by identifying certain polynomial rings with certain moduli. The present paper is the first to make this connection and to apply the representation theory to algebraic proof systems.

Our method and results expand upon work of Ajtai [1, 2]. In connection with a combinatorial problem arising in propositional proof complexity he needed to characterize solvability of symmetric systems of linear equations (we describe his work in Section 2). While working on [18] I noticed that a notion of uniformity used there could yield a lower bound for PC proofs of the modular counting principles represented by the $(N, m)$–systems of [4] if a certain construction with tabloid moduli is made uniform. (No lower bound for these principles follows from [21].) This we achieve by exploiting the constructions in [2] and [13, 12] (in particular, results on Specht modules there).

Another corollary of our method is a strengthening of Ajtai’s results in the form of effective bounds (Theorem 3.5). As an application to algebraic proof complexity we show that the minimum degree of PC–refutations of the $(N, m)$–systems cannot be bounded by an independent constant and, in fact, must be at least $\Omega(\log(\log(N)))$ (where $m$ is not divisible by $p$, the field $F_p$ is
fixed, and \( N \) is a parameter) (Corollary 5.3). No lower bounds for the degree of PC-refutations of these systems were previously known\(^3\).

In fact, we prove a general sufficient condition (Theorem 5.1) implying an \( \Omega(\log(\log(N))) \) lower bound for any family \( \{ f_{N,1}, \ldots, f_{N,k_N} \}_{N<\omega} \) of polynomial systems, provided the family is given in a uniform way, with uniform being defined in terms of first-order logic (or, equivalently by Lemma 1.4, combinatorially). We use this to show also a lower bound for proofs of primality of \( N \), as encoded by a uniform system of equations defined here. The same arguments give \( \Omega(\log(N)) \) lower bounds for NS-proofs (Theorem 5.6).

These explicit non-constant lower bounds are derived from new technical results in Section 3. The reader interested only in the non-existence of constant degree proofs can bypass this section and go to Theorem 5.5. There we prove that families with constant degree PC-refutations admit also constant degree NS-refutations. For this result we need only a bound to the number of submoduli of particular tabloid moduli (Corollary 3.2 which follows already from Ajtai’s work). In particular, a non-constant lower bound for the \((N,m)\)-systems follows from Theorem 5.5 combined with the non-constant degree lower bound for NS from [4]. The non-existence of constant degree NS-refutations for general uniform systems can be derived from Theorem 3.1. Note that linear lower bounds would follow from the non-constant lower bounds (which we proved already in the preliminary version of this paper), should the main theorem announced in [22] hold in characteristic \( p \) (presently it is claimed only in characteristic zero\(^4\)).

We shall not actually use any results or methods from [18] but only a rudimentary notion of uniformity used there, and the entire presentation is self-contained. (In Section 3 we use some definitions and constructions from [13, 12] that are fully described there.)

The reader interested in more background information and in connections to some other topics may consult [15] or the introduction to [6].

Throughout this paper we fix a finite prime field \( \mathbb{F}_p \).

1. Uniform systems of polynomials

We shall define first the \((N,m)\)-system as it nicely motivates the more general definition of uniform polynomial families. Here \( N \) is identified with \( \{0, \ldots, N-1\} \) and \([N]^m\) denotes the set of \( m \)-element subsets of \( N \).

**Definition 1.1** ([4]). Let \( N \geq m \geq 2 \). The variables of the \((N,m)\)-system are \( x_e \), where \( e \) ranges over \([N]^m\). The system consists of the following polynomials:

\(^3\)More than a year after the preliminary version of this paper was available, the paper [7] improved the bounds for the particular \((N,m)\)-systems to \( \Omega(N) \).

\(^4\)As I was told by S. Riis in March ‘98.
(1) \( Q_e := x_e^2 - x_e \), for each \( e \).

(2) \( Q_{e,f} := x_e \cdot x_f \), for every \( e, f \) such that \( e \cap f \neq \emptyset \) but \( e \neq f \).

(3) \( Q_i := 1 - \sum_{e : i \in e} x_e \), for each \( i \in N \).

We identify a polynomial system \( \{ F_i \} \) with the system of equations \( \{ F_i = 0 \} \) and, in particular, the \((N,m)\)-system with the system of equations \( Q_e = 0, Q_{e,f} = 0, Q_i = 0 \).

Assume that \( x_e := a_e \) is a solution of the \((N,m)\)-system in some integral domain. Then, by the equations \( Q_e = 0 \), all \( a_e \) are 0 or 1, and by the remaining equations the set

\[ \{ e \in [N]^m \mid a_e = 1 \} \]

is a partition of \( N \) into \( m \)-element sets. Thus the system has a solution iff \( m \) divides \( N \).

For \( m \) not dividing \( N \) the ideal in \( \mathbb{F}_p[\pi] \) generated by the system is then necessarily trivial (a simple consequence of Nullstellensatz). We shall be interested in the minimum degree of PC-refutations (i.e., proofs of 1) of the system.

The crucial uniformity property (to be defined formally bit later) of the \((N,m)\)-system is the following. Variables are indexed by \( e \in [N]^m \) and equations are naturally indexed by \( e \) (Case 1), by pairs \((e,f)\) (Case 2), and by singletons \( \{i\} \) (Case 3). The permutations of \( N \) act on the (indices of) variables, on (indices of) equations, as well as on monomials and polynomials, and the \((N,m)\)-system is invariant under such actions. This means that the coefficient of a monomial, say \( x_g x_h \), in the equation indexed by, say, \((e,f)\) depends only on the isomorphism type of finite structure \((U;e,f,g,h)\) with universe \( U := e \cup f \cup g \cup h \) and distinguished sets \( e, f, g, h \), but not on \( N \). This invariance property is the key property of families of polynomials systems, which allows us to apply the representation theory of the symmetric group.

We shall first define a general notion of an index, and of uniformity and definability of sets of indices. We will then treat polynomial systems, in particular.

We define uniformity of sets of indices in two equivalent ways. In a logical way as a definability in a certain first order language, and in a combinatorial way in terms of types of finite structures formed from indices. Although the combinatorial version is somewhat more rudimentary and would suffice for the present paper, the logical version allows easier explanation of Ajtai’s work in Section 2, as well as generalizations of the method developed in [18].

**Definition 1.2.** Let \( L(C) \) be a first order language having an element-sort and a set-sort, and consisting of an equality predicate = in both sorts, of a membership relation \( \in \) between elements and sets, and of a finite set \( C \) of element constants. The set-sort can be used only as parameters; i.e., quantifiers may range only over the element-sort.
An $L(C)$–structure $M$ interprets the element-sort by its elements and the set-sort by its subsets. We shall always assume that all constants from $C$ are different in $M$.

Let $k \geq 1$.

1. A $k$–ary index in $M$ is a $k$–tuple $i = (i_1, \ldots, i_k)$ of finite subsets of $M$ such that $k \geq |i_j|$, for $j = 1, \ldots, k$.
2. Index($M,k$) is the set of $k$–ary indices in $M$. The support of $i$ is the set supp($i$) := $\bigcup_j i_j$. The support-size is the cardinality of the support.
3. $M^{(k)}$ is the $\mathbb{F}_p$–vector space whose basis is the set Index($M,k$).
4. A vector from $M^{(k)}$ is definable (tacitly in $L(C)$) over a set $A \subseteq M$ if for each $a \in \mathbb{F}_p$ there is an $L(C)$–formula $\theta_a(\gamma, \alpha)$ with parameters from $C \cup A$, $\alpha = (\alpha_1, \ldots, \alpha_k)$, such that the coefficient of the index $j = (j_1, \ldots, j_k)$ is $a$ iff the formula $\theta_a(j)$ holds in $M$.
5. A family $X_i^{M} \subseteq M^{(k)}$ of sets of vectors from Index($M,k$), with $M$ ranging over finite $L(C)$–structures and $i \in$ Index($M,\ell$), is uniform (or definable) iff there are $L(C)$–formulas $\theta_a(\gamma, \alpha)$, $a \in \mathbb{F}_p$, with no parameters other than $C$, with $\gamma = \gamma_1, \ldots, \gamma_{\ell}$, $\alpha = \alpha_1, \ldots, \alpha_k$ of the set-sort such that for every $M$ and every $i \in$ Index($M,\ell$) the vector $X_i^{M}$ is defined in $M$ by formulas $\theta_a(i, \alpha)$.

The results proved later on hold for a more general notion of an index (roughly, a finite structure of any order with a bounded support), but we avoid such generality here as we have no interesting applications for the general case.

We now characterize definability in a more combinatorial way.

**Definition 1.3.** Let $M$ be an $L(C)$–structure, $A \subseteq M$, $i \in$ Index($M,\ell$), and let $\text{Sym}_C (M/A)$ be the group of permutations of $M$ fixing point-wise the set $C \cup A$. The type of $i$ over $A$, denoted by $\text{tp}_C(i/A)$, is the isomorphism type of the $L(C)$–structure $\langle C \cup \text{supp}(i) \cup A; \{c\}_{c \in C}, \{a\}_{a \in A}, i_1, \ldots, i_\ell \rangle$ with the universe $C \cup \text{supp}(i) \cup A$. The support-size of the type is the cardinality of the set $C \cup \text{supp}(i) \cup A$.

Note that over any $M$, types of $\ell$–ary indices over $A$ are in a bijective correspondence with orbits of $\text{Sym}_C (M/A)$ acting on Index($M,\ell$). The following lemma is a simple model-theoretic fact. Note that it is important that we allow quantification only over the element-sort.

**Lemma 1.4.** Let $L(C)$, $A$ and $\ell$ be fixed. Then the following two statements hold:

1. For any $L(C)$–formula $\psi(\alpha)$, $\alpha = \alpha_1, \ldots, \alpha_\ell$, with parameters from $A$ there is a (necessarily finite) set $S$ of types over $A$ of $\ell$–ary indices
such that for each $M \supseteq A$ large enough (depending on the formula $\psi$) and every $i \in \text{Index}(M, r)$

\[ M \models \psi(i) \iff \text{tp}_C(i/A) \in S. \]

(2) For any (necessarily finite) set $S$ of types over $A$ of $r$–ary indices there is a quantifier-free formula $\psi(\alpha)$ with parameters from $A$ such that for every $M$ and every $i \in \text{Index}(M, r)$

\[ M \models \psi(i) \iff \text{tp}_C(i/A) \in S. \]

In particular, let $X^M \subseteq \text{Index}(M, r)$, with $M$ ranging over $\text{L}(C)$–structures containing $A$, be a family of sets of $r$–ary indices. Then $X^M$ is definable by an $\text{L}(C)$–formula iff it is definable in terms of types (for $M$ large enough).

We now discuss an embedding of polynomial rings into vector spaces $M(r)$.

**Definition 1.5.** Let $M$ be an $\text{L}(C)$–structure, and let $k \geq 1$.

(1) $\text{Var}(M, k)$ is the set of variables indexed by elements of $\text{Index}(M, k)$ different from $\emptyset = (\emptyset, \ldots, \emptyset)$. (The index $\emptyset$ will represent 1 in monomials.)

(2) $\text{Mon}(M, k, d)$ is the set of all monomials formed from $\text{Var}(M, k)$ and of degree at most $d$. Monomials from $\text{Mon}(M, k, d)$ are identified with indices from $\text{Index}(M, kd)$, utilizing the index $\emptyset$ for monomials of degree $\leq d$. In particular, the monomial $x_{i_1}x_{i_2}\ldots x_{i_\ell}$, $i^t = (i_1^t, \ldots, i_\ell^t)$, is identified with the $kd$–ary index $(i_1^t, \ldots, i_\ell^t, \emptyset, \ldots, \emptyset)$.

(3) A polynomial over $M$ is a function from some set $\text{Mon}(M, k, d)$ to $F_p$.

It is definable over a set $A \subseteq M$ if for each $a \in F_p$ there is an $\text{L}(C)$–formula $\theta_a(\alpha)$ with parameters from $C \cup A$, $\alpha = (\alpha_{1,1}, \ldots, \alpha_{1,k}, \ldots, \alpha_{d,1}, \ldots, \alpha_{d,k})$ such that the coefficient of the monomial $x_{j_1,1} \ldots x_{j_\ell,1} \cdots x_{j_1,k} \cdots x_{j_\ell,k}$ is $a$ iff the formula $\theta_a(j)$ holds in $M$. $\text{Poly}(M, k, d)$ is the set of monomials of degree at most $d$ with variables from $\text{Var}(M, k)$.

(4) A family $F^M_i$, with $M$ ranging over finite $\text{L}(C)$–structures and $i \in \text{Index}(M, \ell)$, of polynomials with variables from $\text{Var}(M, k)$ and of degree at most $d$ is uniform (or definable) iff there are $\text{L}(C)$–formulas $\theta_a(\gamma, \alpha)$, $a \in F_p$, with no parameters other than $C$, with $\gamma = \gamma_1, \ldots, \gamma_\ell$, $\alpha = (\alpha_{1,1}, \ldots, \alpha_{d,k})$ of the set-sort such that for every $M$ and every $i \in \text{Index}(M, \ell)$ the polynomial $F^M_i$ is defined in $M$ by formulas $\theta_a(i, \alpha)$.

We shall use the notations $F^M(i, j)$ or $F^M_{i,j}$ to denote the unique $a \in F_p$ such that $\theta_a(i, j)$ holds in $M$, and we shall write $F^M = \sum_j F^M(i, j)x^j$, where $x^j$ (sometimes written only as $j$) denotes the monomial corresponding to index $j$. 
Note that, in particular, Lemma 1.4 says that a family $F^M$ is uniform iff the value $F^M(i, j) \in \mathbb{F}_p$ depends only on the type $\text{tp}_C((i, j))$ of the pair of indices $(i, j)$ (for $M$ large enough).

The reason for the somewhat unnatural embedding of monomials of degree $\ell \leq d$ into $kd$-ary indices is that we need a fixed number of variables $\alpha_{ij}$ for formulas $\theta(a)$ defining polynomials.

The representation of monomials by indices does not account for the commutativity of variables. As we wish to work only in the commutative context we remedy the situation by including in all families $F$ a particular uniform family $\text{COMM}^k$.

**Definition 1.6.** $\text{COMM}^k$ is a uniform family indexed by pairs $i, j$ of elements $\text{Var}(M, k)$, with the polynomial $\text{COMM}^k_{i,j}$ being $x_i x_j - x_j x_i$.

We conclude this section with two technical lemmas.

**Lemma 1.7.** Let $r \geq 1, s \geq 0$, let $A \subseteq M$, and let $\omega$ be a type of an $r$-index $i = (i_1, \ldots, i_r)$ over $A$, and $s$ the support-size of $\omega$. If $|M| \geq s$, then the cardinality of

$$\{i \in \text{Index}(M, r) \mid \text{tp}_C(i/A) = \omega\}$$

modulo $p$ depends only on the remainder of $|M|$ modulo $p^\nu$, for any $p^\nu > r^{r^2/2}$.

**Proof.** A type is given by $2^r - 1$ numbers $m_1, \ldots, m_{2^r - 1}$ specifying the number of elements of $M \setminus (A \cup C)$ in all regions of the Venn diagram of $i_1, \ldots, i_r$ inside $\text{supp}(i)$, together with a placement of constants from $C \cup A$ in these regions. Clearly $|C \cup A| + \sum_j m_j = s$, so if $|M| \geq s$, the number of $r$-indices for a given $C, A$ with the type specified by the $m_j$’s is

$$K := \frac{(M') (M' - m_1) \cdots (M' - \sum_{j=1}^{2^r - 2} m_j)}{m_2} \cdots \frac{(M' - \sum_{j=1}^{2^r - 1} m_j)}{m_{2^r - 1}}$$

where $M' := |M| - |A \cup C|$.

To determine $K \mod p$ it is enough to know

$$M'(M' - 1) \cdots (M' + 1 - \sum_{j=1}^{2^r - 1} m_j)$$

modulo the power of $p$ in the product in the denominator. As $\prod_{j=1}^{2^r - 1} (m_j!) \leq (r!)^{r/2} \leq r^{r^2/2}$, knowing $M'$ modulo any power $p^\nu > r^{r^2/2}$ will do. \qed
The following lemma is a simple corollary of the previous statement. Recall that, for a polynomial \( f \in \text{Poly}(M, k, t) \) and a monomial \( j \in \text{Mon}(M, k, t) \), \( f_j \) is the coefficient of \( j \) in \( f \).

**Lemma 1.8.** Let \( A, B \subseteq M \) and let \( k, t \geq 1 \). Let \( f, g \in \text{Poly}(M, k, t) \) be polynomials defined over \( A \) and \( B \) respectively. If \( |M| \geq |A \cup B \cup C| + k^2t \), then the value
\[
\sum_{j \in \text{Mon}(M, k, t)} f_j \cdot g_j \in \mathbb{F}_p
\]
depends only on \( |M| \mod p^\nu \), for any \( p^\nu > (kt)^{2t}/2 \).

2. Ajtai’s work on definability of solutions of uniform systems of linear equations

Ajtai [2] studied\(^5\) in a very interesting work the definability (in certain expansions \( M^* \) of the original structures \( M \)) of solutions of uniform systems of linear equations.

**Definition 2.1.** Let \( \nu \geq 1 \) and \( s \geq 0 \) be fixed.

(1) \( L^{\nu,s} \) is the language expanding \( L(C) \) by the following (element-sort) constants and predicates: constants \( e_0, e_1 \), unary predicates \( R_{\nu,j}(x) \) for \( j = 0, \ldots, p^\nu - 1 \), and binary predicates \( x \leq y \) and \( D_i(x, y) \), for \( i = 0, \ldots, s \). The \( L^{\nu,s} \)-formulas are assumed to maintain the property that no quantifier ranges over the set-sort.

(2) \( T^{\nu,s} \) is the \( L^{\nu,s} \)-theory with the following axioms:
   (a) \( \leq \) is a linear ordering with \( e_0 \) and \( e_1 \) the first and the last elements, respectively.
   (b) \( R_{\nu,1}(e_0) \) holds and \( R_{\nu,j}(a) \) implies \( R_{\nu,j'}(a') \), whenever \( a' \) is the successor of \( a \) and \( j' = j + 1 \mod p^\nu \).
   (c) \( D_i(a, b) \) holds iff the distance between \( a \) and \( b \) is \( i \).

It is clear that \( T^{\nu,s} \) admits a form of quantifier elimination (verified by induction on the size of a formula, cf. [2, Lemma 8]).

**Lemma 2.2.** Let \( \phi \) be an \( L^{\nu,0} \)-formula. Then there is \( s \geq 0 \) depending only on \( \nu \) and on the size of \( \phi \), and a quantifier-free \( L^{\nu,s} \)-formula \( \psi \) such that \( \phi \) and \( \psi \) are equivalent in any model \( M^* \) of \( T^{\nu,s} \) of sufficiently large cardinality.

The lemma explains why \( L^{\nu,0} \)-definability of a property of structures \( M \) implies that the property depends only on the cardinality of \( M \) modulo \( p^\nu \).

This is because if \( \phi \) is a sentence then it is equivalent to a boolean combination of conditions \( R_{\nu,j}(e_1) \), for some \( j < p^\nu \) (for \( M^* \) large enough).

---

\(^5\)The presentation of [2] is rather unfriendly. However, readers willing to suffer are rewarded.
Ajtai [2] proved a remarkable theorem, stated below using our notion of uniformity. We will derive later (see Theorem 3.5) the equivalence of conditions 1 and 3 in this theorem from Lemma 1.8 and Theorem 3.3 (with effective bounds on sufficiently large).

**Theorem 2.3 (Ajtai [2]).** Let $L(C)$ and $k, \ell \geq 1$ be given. Assume that a family $F^M_i$, $i \in \text{Index}(M, \ell)$, is a uniform family of linear polynomials with variables from $\text{Var}(M,k)$. Then there exists $\nu \geq 1$ (depending only on $|C|, k, \ell$ and tacitly on $p$) and a set $Q \subseteq \{0, \ldots, p^{\nu-1}\}$ such that for every sufficiently large finite $L(C)$–structure $M$ the following three statements are equivalent:

1. The system $\{F^M_i = 0\}_{i \in \text{Index}(M,\ell)}$ is solvable in $\mathbb{F}_p$.
2. The system $\{F^M_i = 0\}_{i \in \text{Index}(M,\ell)}$ has a solution in $\mathbb{F}_p$ that is $L_0^{\nu,0}$-definable in any expansion $M^*$ of $M$ to a model of $T^{\nu,0}$. The definition of the solution is common for all $M$.
3. $|M| \equiv r \mod p^{\nu}$ for some $r \in Q$.

Ajtai states the theorem using the notion of a family induced by quadruples. For the benefit of a reader familiar with [1, 2] we now include a proof that our notion of uniformity (definability) coincides with that notion, and hence that our formulation is equivalent to the original one. (The theorem, however, is not needed anywhere else in the paper, and the part of this theorem that we shall use will actually be deduced in full from our results.)

By Theorems 1 and 2 (using Lemma 1.4 here) and Corollary 6 of [2] (and its extension discussed in the last section of [2]; see also [1, Theorem 4]) it is enough to show that if a family is uniform then it is induced by a quadruple (as defined on pp. 4-5 of [2]). In fact, we show that these two notions coincide.

A quadruple is in our setting equivalent to a finite set of the following data that we shall call a pattern. (We give the definition for any $d \geq 1$ as this will be needed later on.) A pattern is an $\ell$–ary index $i$ and a set $X \supseteq C \cup \text{supp}(i)$ such that $|X \setminus (C \cup \text{supp}(i))| \geq k^2 d$, and a mapping $u : \text{Mon}(X,k,d) \to \mathbb{F}_p$ such that $u(j) = u(j')$ if $\text{tp}_{C}(j/\text{supp}(i)) = \text{tp}_{C}(j'/\text{supp}(i))$.

The pattern uniquely determines a polynomial of degree at most $d$ with variables from $\text{Var}(M,k)$,

$$\sum_j u(\pi_j(j))x^j,$$

where $\pi_j \in \text{Sym}_C(M/\text{supp}(i))$ is any permutation moving $j$ into $\text{Mon}(X,k,d)$. Hence the coefficient of $x^j$ depends only on $\text{tp}_C(j/\text{supp}(i))$ and so, by Lemma 1.4, the polynomial is definable over $\text{supp}(i)$.

The pattern $(X,i,u)$ corresponds to a uniform system of polynomials $F$ as follows. The polynomials in $F$ are indexed by $\pi(i)$ for $\pi \in \text{Sym}_C(M)$, and the coefficient of $x^j$ in the polynomial $F_{\pi(i)}$ is the coefficient of $x^{\pi^{-1}(j)}$ in the polynomial determined by the pattern. The system is uniform by Lemma
1.4 again, as \( F(i,j) \) depends only on \( \text{tp}_C((i,j)) \). Hence a quadruple (a finite collection of patterns) corresponds to a uniform family too.

On the other hand, a uniform system \( F \) is described by a quadruple as follows. For every type \( \omega \) of an index \( i \) (there are only finitely many) choose \( i_\omega \) such that \( \text{tp}_C(i_\omega) = \omega \). For \( X_\omega \) take any set extending \( C \cup \text{supp}(i_\omega) \) by \( k^2d \) elements, and define \( u_\omega \) by

\[
u_\omega(j) := F(i_\omega, j).
\]

The quadruple consists of all patterns \( (X_\omega, i_\omega, u_\omega) \). Hence we have shown that every uniform system corresponds to a quadruple of patterns of bounded size (at most \(|C| + \ell^2 + k^2 \) for \( d = 1 \)). Thus Ajtai’s theorem applies.

3. Definable generators of permutation moduli

The ambient space for moduli will be the \( \mathbb{F}_p \)-vector space \( M^{(r)} \) defined in Definition 1.2. Recall that \( \text{Poly}(M,k,t) \) is a subspace of \( M^{(k,t)} \). Tabloid moduli (see below) will provide other examples of subspaces of \( M^{(r)} \).

Let \( W \) be a subset of \( M^{(r)} \). The group \( \Sym_C(M) \) acts on \( M^{(r)} \) and we say that \( W \) is symmetric iff it is closed under this action. A symmetric \( W \) that is also a vector subspace of \( M^{(r)} \) is thus an \( \mathbb{F}_p[\Sym_C(M)] \)-module, where \( \mathbb{F}_p[\Sym_C(M)] \) is the group algebra (corresponding to the group algebra denoted by \( \mathbb{Z}_pS_n \) in [2]; we use here the notation of [20]).

We shall say that a set \( G \) generates \( W \) iff it generates \( W \) as an \( \mathbb{F}_p[\Sym_C(M)] \) module, and that it generates \( W \) as a vector space iff \( W \) is the \( \mathbb{F}_p \)-linear span of \( G \).

We recall now several definitions and facts from [13, 12]. Let \( \mu = (\mu_1, \ldots, \mu_s) \) be a partition of \( N := |M| \); i.e., the \( \mu_i \)'s are non-negative integers such that \( \sum_i \mu_i = N \). A partition is proper iff \( \mu_1 \geq \mu_2 \geq \cdots \geq \mu_s \).

A \( \mu \)-tableloid is an index that is an ordered \( s \)-tuple \( T = (T_1, \ldots, T_s) \) of disjoint subsets of \( M \) such that \(|T_i| = \mu_i \). A \( \mu \)-tableaux \( t \) is a \( \mu \)-tableloid \( T \) together with linear orderings of all \( T_i \)'s. The underlying tableoid is denoted by \( \{t\} \) (in accordance with [13, 12]). Tableoid \( T \) has rows \( T_1, \ldots, T_s \), and tableaux \( t \) has also columns consisting of the first, second, etc., elements of the rows. The support-size of \( T \) is \( \sum_{j \geq 2} |T_j| \).

The tableoid module \( M^\mu \) is an \( \mathbb{F}_p \)-vector space whose basis is the set of all \( \mu \)-tableoids. \( \Sym_C(M) \) acts on tableoids, and hence on elements of \( M^\mu \), and \( M^\mu \) is \( \mathbb{F}_p[\Sym_C(M)] \)-module. Note that tableoid \( T \) is determined by the rows \( T_2, \ldots, T_s \); hence \( M^\mu \) is \( \mathbb{F}_p[\Sym_C(M)] \)-isomorphic to a submodule of \( M^{(r)} \), where \( s - 1 \leq r \) and \(|T_i| \leq r\), all \( i \geq 2 \). The embedding sends a tableoid \( T \) to the \( r \)-index \( \text{ind}(T) := (T_2, \ldots, T_s) \).

On the other hand, \( M^{(r)} \) is isomorphic to a submodule of a direct sum of tableoid moduli. To see this note that the \( 2^r \) intersections \( Y_1 \cap \cdots \cap Y_s \), where \( Y_j \) is either \( i_j \) or its complement \( M \setminus i_j \), form a partition of \( M \) that determines
the $r$–index $i$. (Not all partitions of $M$ are obtained in this way, so we get a submodule.) This encoding of $r$–indices by tabloids is formalized as follows.

For $X \subseteq M$ put $X^1 := X$ and $X^0 := M \setminus X$, and for $i \in \text{Index}(M, r)$ and $\epsilon \in \{0, 1\}^r \setminus \{(0, \ldots, 0)\}$ put

$$i^\epsilon := \bigcap_{t \leq r} i^t \epsilon^t.$$

Note that the $i^\epsilon$ are disjoint, for different $\epsilon$, have size at most $r$, and that $i = i'$ iff $i^\epsilon = i'^\epsilon$ for all $\epsilon \in \{0, 1\}^r \setminus \{(0, \ldots, 0)\}$. Define the tabloid (not necessarily corresponding to a proper partition)

$$\text{tab}(i) := (M \setminus \text{supp}(j), j_1, \ldots, j_{2r-1}),$$

where $j \in \text{Index}(M, 2r-1)$ is an index whose coordinates are numbered by $\epsilon \in \{0, 1\}^r \setminus \{(0, \ldots, 0)\}$ in the lexicographic order and such that the $\epsilon$th coordinate is the set $i^\epsilon$.

Let $\mu^j$ range over partitions corresponding to all $\text{tab}(i)$, $i \in \text{Index}(M, r)$. As $|\text{supp}(i)| \leq r^2$, there are only finitely many such $\mu^j$'s (depending on $r$). The map $\text{tab}$ is an embedding of $M^{(r)}$ into $\bigoplus_j M^{\mu^j}$. The map $\text{ind}$ is not its inverse, but the definitions of $X \subseteq M^{(r)}$ clearly correspond to those of $\text{ind}(\text{tab}(X))$ (as rows in $\text{ind}(\text{tab}(i))$ correspond to the inner regions of the Venn diagram of $i$). Note that the support-sizes of $i$ and $\text{tab}(i)$, and of $T$ and $\text{ind}(T)$ are the same.

We use this correspondence to extend the notion of definability and uniformity from Section 1 to tabloid modules: by definability from $A$ of a subset $W$ of a tabloid module $\bigoplus_j M^{\mu^j}$ we mean the $L(C)$–definability of $\text{ind}(W)$ from constants $A$. More generally, $v \in \bigoplus_\lambda M^\lambda$ is definable from $A$ if for every $\lambda$ the set $\text{ind}(\text{pr}_\lambda(v)) \subseteq \text{ind}(M^\lambda)$ is definable from $A$, where $\text{pr}_\lambda$ is the projection on $M^\lambda$. In particular, each $\text{ind}(\text{pr}_\lambda(v))$ has its own $L(C)$–formula defining it. Note that in the particular case $\bigoplus_\lambda M^\lambda = \bigoplus_j M^{\mu^j} = \text{tab}(\text{Index}(M, r))$ the notions are the same, as each $\mu^j$ corresponds to a different type of $r$–indices and hence all the (possibly different) definitions for $\text{ind}(\text{pr}_{\mu^j}(v))$ can be incorporated into a single definition using a definition by cases distinguishing the type of $\mu^j$.

In the more general direct sum some $\lambda$'s may occur several times. Note also that $\text{Poly}(M, k, t) \subseteq M^{(kt)}$ and that definability results for $M^{(kt)}$ pull-back to $\text{Poly}(M, k, t)$ as it is itself definable in $M^{(kt)}$ (without parameters).

In our terminology Ajtai’s theorem [2, Theorems 7 and 7’] says the following.

**Theorem 3.1 (Ajtai [2]).** Let $M$ be a finite $L(C)$–structure and let $W$ be a submodule of $M^{(r)}$. Then there is $\nu \geq 1$ depending only on $r$, and a set $G \subseteq W$ generating $W$ such that the following holds:

1. The cardinality of $G$ depends only on $r$ but not on $M$. 

Every element of $G$ is $L^{\nu,0}$-definable in any expansion $M^*$ of $M$ to a model of $T^{\nu,0}$ by formulas of size bounded in terms of $r$ only.

We shall not use this theorem, but we note its immediate corollary (that was in a special case also obtained by D.G.D. Gray [10, 11]). Explicit bounds on $c$ can be computed from our Theorem 3.3 below.

**Corollary 3.2.** Given $r$ there is $c$ such that for any $M$ the module $M^{(r)}$ has at most $c$ different submoduli.

Our main technical result is the following theorem describing another form of defining sets of generators for submoduli of $M^{(r)}$. The construction is partly based on Ajtai’s construction underlying Theorem 3.1 and partly on constructions from [13, 12] describing the Specht modules and their orthogonal complements as kernels and ranges of suitable linear maps.

We give a proof utilizing some facts related to tabloid moduli from [13, 12]. (These are also explained in the proof of Lemma 3.4.)

Denote by $M^{(r,s)}$ the submodule of $M^{(r)}$ generated by those $i \in \text{Index}(M,r)$ whose support-size is at most $s$. So, in particular, $M^{(r)} = M^{(r,r^2)}$ and $M^{(r,0)} \cong \mathbb{F}_p$. Note that $M^{(r,s)}$ is a submodule of $M^{(r')}$ if $r \leq r'$ with an associated natural projection. For $K$ a uniform family of linear polynomials $K_i$ with variables indexed by $r'$–indices denote by $V(K^M)$ the vector subspace of $M^{(r')}$ consisting of solutions to the homogeneous system $\{K_i x = 0\}_i$, and by $V_{r,s}(K^M)$ the projection of $V(K^M)$ onto $M^{(r,s)}$.

**Theorem 3.3.** Given $r, s \geq 1$ there are $c, \ell \geq 1$ and $r' \geq r$, uniform families $H^1, \ldots, H^c$ of vectors from $M^{(r,s)}$ and uniform families $K^1, \ldots, K^c$ of vectors from $M^{(r')}$ such that the following holds:

1. The vectors $H_i^t$ and $K_i^t$ in the families $H^t$ and $K^t$, $t \leq c$, respectively, are indexed by ordered $\ell$-tuples $i$ such that the support-size of each $i$ is at most $2s^2$.
2. For every $M$ of size at least $|C| + 2s^2$, if $s < p$ then any submodule $W$ of $M^{(r,s)}$ is generated as a vector space by one of the systems $(H^t)^M$.
3. For every $M$ of size at least $|C| + 2s^2$, any submodule $W$ of $M^{(r,s)}$ is $V_{r,s}(K^t)^M$ for a $K^t$, $t \leq c$.

**Proof.** Assume $|M| \geq |C| + 2s^2$. We shall show that any submodule $W$ of $M^{(r,s)}$ is a span of some $H^M$, where $H$ is a uniform family indexed by $\ell$–tuples of support-size at most $2s^2$. For a fixed $\ell$ there are a priori finitely many such uniform families as there are finitely many types of pairs $(i, j)$ of indices of $H(i, j)$, and as we are working over a finite field. (This latter condition is, in fact, not necessary but this follows only from the construction.)
The existence of a suitable $H$ is proved by an induction argument of a structure that is, in part, similar to the proof of [2, Theorems 7 and 7']. (We modify the induction and use a construction from [12] in place of a duality argument in [2].) The construction yields families $K^t$ in any characteristic and families $H^t$ if $p > s$; this assumption is used only in Lemma 3.4 (Part 2).

We shall first motivate the general set-up for the induction by considering a special case. This allows us also to introduce a few necessary concepts.

Let $W \subseteq M(r,s)$. By the embedding $tab$ we may identify $W$ with a submodule of some sum $\bigoplus M^\mu$, where each $\mu$–tabloid has support-size at most $s$. Consider the special case when, in fact, $W$ is a submodule of a single $M^\mu$ and when $\mu$ is proper.

By James' submodule theorem [13, Theorem 4.8] either $S^\mu \subseteq W$ or $W \subseteq (S^\mu)^\perp$, where $S^\mu$ is the Specht module. Let $\psi_{i,v}$ be the maps $M^\mu \rightarrow M^{\lambda^i v}$ from [13, Definition 17.10] (see the proof of Lemma 3.4 for the definition) and let

$$\eta := \bigoplus_{i=1}^{2^r-1} \bigoplus_{v=0}^{\mu_{i+1} - 1} \psi_{i,v}$$

be the map $M^\mu \rightarrow Y^\mu$, where $Y^\mu := \bigoplus_{i,v} M^{\lambda^i v}$.

If $S^\mu \subseteq W$, take $U := \eta(W) \subseteq Y^\mu$ and assume that $G \subseteq U$ spans $U$. Then $H := \eta^{-1}(G) \cup S^\mu$ spans $W$ as $S^\mu = \ker(\eta)$ by [13, Corollary 17.18]. In fact, in place of $\eta^{-1}(G)$ it is enough to have one representative for every fiber of $\eta$ over $G$, as $\eta(u) = \eta(v)$ implies $u - v \in S^\mu$.

If, on the other hand, $W \subseteq (S^\mu)^\perp$, we use the maps $\varphi_{i,v} : M^{\lambda^i v} \rightarrow M^\mu$ from [12] (denoted there by $\psi_{i,v}$; for the definition see the proof of Lemma 3.4). Let $\rho := \sum_{i,v} \varphi_{i,v} \circ \text{pr}_{\lambda^i v} : Y^\mu \rightarrow M^\mu$ be the sum of these maps (with the same range for $i,v$ as in $\eta$). Take $U := \rho^{-1}(W) \subseteq Y^\mu$, and assume that $G \subseteq U$ spans $U$. By [12, Corollary 3], $\rho(Y^\mu) = (S^\mu)^\perp$, so $H := \rho(G)$ spans $W$ in this case.

Hence in either case we construct a spanning set $H$ for $W$ from a spanning set $G$ for $U$. To get a good estimate on the parameters of such families we shall proceed slightly differently. We shall construct a set $H' \subseteq W$ that generates $W$ (as a module) from a generating set $G'$ for $U$, and in the construction we shall estimate the growth of the number of parameters needed to define any vector in the generating set. In the course of the construction we also derive an estimate for the cardinality of $H'$. Given such a set $H'$, we shall construct a uniform family $\tilde{H}$ explicitly in Claim 3.

To make this construction work, it will be enough to show:

1. $S^\mu$ is spanned by a uniform family indexed by $2s$–tuples.
(2) If \( p > s \), then for any \( w \in Y^\mu \) definable over \( A \), element of \( \eta^{(-1)}(w) \) of \( M^\mu \) is definable over some \( A' \) such that \( |A' \setminus A| \leq 2s^2 \). Hence the pull-back \( \eta^{(-1)}(G') \) together with \( S^\mu \) is generated by a set in which every vector is defined from the same tuples as those in \( G' \) augmented by \( 2s^2 \)–tuples or from \( 2s \)–tuples.

(3) The image \( \rho(w) \in M^\mu \) of any \( w \in Y^\mu \) definable over \( A \) is also definable over \( A \). Hence the image \( \rho(G') \) is a generating set parametrized by the same indices as \( G' \).

(4) Some suitable \( G' \) exists.

This will be the basis of an induction argument as the module \( Y^\mu \) is in a sense simpler than \( M^\mu \). (It does not contain the irreducible factor \( D^\mu := S^\mu / (S^\mu \cap S^\mu \perp) \), cf. [13].) The first three of these conditions will be guaranteed by Lemma 3.4 and the last condition will amount to the induction hypothesis.

We describe first the inductive construction of \( H' \), then give a bound \( \ell \) for the number of parameters and construct \( H \), and describe the construction of systems \( K^i \).

For any \( \mu \) let \( \tilde{\mu} \) be the reordering of \( \mu \) that is proper. So \( \mu = \tilde{\mu} \) for proper \( \mu \). We assume that \( \mu_1 \geq \sum_{j \geq 2} \mu_j \), so \( \tilde{\mu}_1 = \mu_1 \). (Since \( |M| \geq 2s \) and the support-size of any starting \( \mu_j \) is at most \( s \), this holds for all starting \( \mu_j \)’s.) For any partition \( \lambda^{i,v} \) occurring in the definition of \( \eta \), \( \tilde{\lambda}^{i,v} \) is lexicographically bigger than \( \mu \), provided \( \mu \) is proper. Moreover, the support-size of \( \lambda^{i,v} \) is at most the support-size of \( \mu \).

We shall consider sets \( X \) of partitions where a partition may occur with repetitions; these will be called multi-sets. We shall study definability of elements of \( \bigoplus_{\lambda \in X} M^\lambda \). Recall (from the beginning of this section) that \( v \in \bigoplus_{\lambda \in X} M^\lambda \) is definable over \( A \) if each projection \( \text{pr}_{M^\lambda}(v) \in M^\lambda \) (with different projections for different occurrences of \( M^\lambda \) in the direct sum) is definable over \( A \) by a separate definition \( B_\lambda(\pi) \). For this purpose we may always replace any \( \lambda \) by \( \lambda \) and permute, in a suitable way, the \( \alpha \)'s in \( B_\lambda \). Thus we may assume without a loss of generality that all partitions in \( X \) are proper.

For a multi-set \( X \) of proper partitions all of which have the support-size at most \( s \) we describe the following operation. Let \( \mu \) be the lexicographically minimal partition occurring in \( X \) that is different from the maximal \( (N,0,\ldots,0) \). (If no such partition exists the operation is undefined.) Take any occurrence of it in \( X \) and replace it by all \( \lambda^{i,v} \) from the definition of \( \eta \), replacing further those \( \lambda^{i,v} \) that are not proper by \( \tilde{\lambda}^{i,v} \). The new multi-set is denoted by \( X^{s\text{ucc}} \).

Consider the class \( \mathcal{X} \) of all such multi-sets \( X \) that can be obtained by repeated applications of the operation to the set \( X_{\text{min}} \) of all partitions corresponding to all \( \text{tab}(i) \), for all \( i \in \text{Index}(M,r) \) of the support-size at most \( s \) (i.e., to the set of \( \mu^j \)'s at the beginning, with \( \mu^j \) possibly replaced by \( \tilde{\mu}^j \)).
The property that $Y$ occurs later than $X$ in the sequential generation (which is unique) of $\mathcal{X}$ from $X_{\min}$ defines a strict linear order $Y \succ X$ on $\mathcal{X}$ (by the remark above about the lexicographic ordering of proper $\mu$ and $\hat{\lambda}^{i,v}$), the multi-set $M_{\min}$ is $\succ$-minimal, and the $\succ$-maximal multi-set $X_{\max}$ has the form of several copies of the lexicographically biggest partition $(N,0,\ldots,0)$. Denote by $d(X)$ the number of $Y \succ X$; hence $d(X_{\max}) = 0$ and $d(X_{\min}) = |\mathcal{X}| - 1$.

Claim 1: $|X_{\min}| \leq 2(r+2)s$, $|\mathcal{X}| \leq 2(r+2)s^2$, and any multi-set $X \in \mathcal{X}$ has size (counting multiplicities) at most $2(r+2)s^2$.

Proof. We estimate the cardinality of $X_{\min}$ by the number of partitions $\mu = (\mu_1,\ldots,\mu_{2^s})$ such that $\sum_{j \geq 2} \mu_j \leq s$. This is

$$\binom{s + 2^r - 1}{s} \leq (2^r + s)^s \leq (2^r + r^2)^s \leq 2^{(r+2)s}.$$

There are at most $2^s$ different proper partitions of support-size $\sum_{j \geq 2} \mu_j \leq s$. Call the number of $\hat{\mu}$ in the lexicographic ordering of such proper partitions the level of $\mu$, level 1 corresponding to the lexicographically largest partition $\hat{\mu} = (N,0,\ldots,0)$ and the largest level $h_{\max}$ to the smallest $\hat{\mu}$. Now, $X_{\min}$ has at most $|X_{\min}|$ elements in the maximal level $h_{\max} \leq 2^s$. So after at most $|X_{\min}|$ steps we get $Y$ with all partitions in level $\leq h_{\max} - 1$, and of size $|Y| \leq |X_{\min}| \cdot (s - 1)$. The factor $(s - 1)$ comes from the fact that the number of $\hat{\lambda}^{i,v}$'s is $\leq s - 1$. Getting rid of level $(h_{\max} - 1)$–partitions in $Y$ requires at most $|Y|$ steps, increasing the size of $Y$ to at most $|X_{\min}| \cdot (s - 1)^2$. So the entire process until reaching $X_{\max}$ needs at most

$$|\mathcal{X}| \leq \sum_{t=0}^{2^s} |X_{\min}|(s - 1)^t \leq 2^{(r+2)s} \cdot s^{2^s}$$

steps, and any $Y$ occurring in it has a cardinality bounded by the same quantity

$$|Y| \leq 2^{(r+2)s} \cdot s^{2^s}.$$

This proves the claim. \qed

Using $\succ$–downwards induction, we shall prove, for any $X \in \mathcal{X}$, the following statement:

For any submodule $U \subseteq \bigoplus_{\lambda \in X} M^\lambda$ there is $H' \subseteq U$ generating $U$ and such that any vector in $H'$ is definable from a $2s^2d(X)$–tuple. Moreover, the size of $H'$ is at most $2^{(r+2)s} s^{2^s} + d(X)$.

Consider the initial case $X := X_{\max}$. The module $M^\mu$ for $\mu = (N,0,\ldots,0)$ is just the field $F_p$, so $\bigoplus_{\lambda \in X} M^\lambda = F_p \oplus \cdots \oplus F_p$, with $|X_{\max}| \leq 2^{(r+2)s} \cdot s^{2^s}$ copies of $F_p$.

Any particular vector in this module is definable without parameters (as there is a separate definition for any coordinate picking an element of $F_p$). It
is also enough to take \( |X_{\text{max}}| \) of these vectors in any generating set \( H' \), as this is the maximal dimension. This proves the initial case of the induction.

For the induction step assume that the statement holds for all \( Y \succ X \). Let \( X_0 \subseteq X \) be the multi-set of all occurrences of the partition \( \mu \) that is replaced in the operation (i.e., \( \mu \) is the lexicographically minimal partition). Let

\[
W \subseteq \bigoplus_{\lambda \in X} M^\lambda = \bigoplus_{\mu \in X_0} M^\mu \oplus \bigoplus_{\lambda \in X \setminus X_0} M^\lambda.
\]

Let \( u \in \bigoplus_{\lambda \in X} M^\lambda \) and let \( t \) be a \( \mu \)-tableaux and \( \kappa_t \) its signed column sum. Consider the coordinate \( u_\lambda = \text{pr}_{\lambda^*}(u) \) of \( u \) in \( M^\lambda \). By [13, Lemma 4.6 and Corollary 4.7], \( u_\lambda \kappa_t = 0 \) for all \( \lambda \) that are lexicographically greater than \( \mu \) (as the lexicographical ordering refines the partial ordering \( \supseteq \) used in [13]; see [13, Definitions 3.2 and 3.4]), and \( u_\lambda \kappa_t = c \cdot e_t \) for some \( c \in F_p \), if \( \lambda = \mu \). Thus \( u_\lambda \kappa_t \in \bigoplus_{\lambda \in X} M^\lambda \) is a vector whose first \( |X_0| \) coordinates are \( F_p \)-multiples of the polytabloid \( e_t \) and all other coordinates corresponding to \( \lambda \in X \setminus X_0 \) are zero.

Fix a \( \mu \)-tabloid \( t \) and take \( X_1 \subseteq X_0 \) to be the set of all occurrences of \( \mu \)'s such that for some \( u \in W \), \( u_\lambda \kappa_t \) has a non-zero coordinate corresponding to the particular \( \mu \) (and hence is a non-zero \( F_p \)-multiple of \( e_t \)). Using the occurrences from \( X_1 \) as the first \( k := |X_1| \) occurrences of \( \mu \) in the direct sum, we may assume that we have \( k \) vectors \( u^1, \ldots, u^k \in W \) such that \( u^i_\lambda \kappa_t \) has its first \( k \) coordinates of the form \( c_{i,j} \cdot e_t \), \( j = 1, \ldots, k \), and all other coordinates zero, with all \( c_{i,i} \neq 0 \).

Let \( X_2 \subseteq X_1 \) be the maximal set such that there are \( u^1, \ldots, u^k \in W \) with \((u^i_\lambda \kappa_t)_j = c_{i,j} e_t\) and an invertible \( k \times k \) matrix \( E \) with entries from \( F_p \) such that the following holds: the vectors \( v^i \) with entries \( v^i_j := \sum_{m \leq k} c_{i,m} E_{m,j} \) for \( j \leq k \), and \( v^i_j := 0 \) for \( j > k \) are such that \( v^i_j = 1 \) iff \( i = j \in X_2 \) and \( v^i_j = 0 \) otherwise. The vectors \( v^i \) are in \( \bigoplus_{\lambda \in X} M^\lambda \) and the map defined by \( \kappa_t \) and \( E \) (mapping \( u \) to \( u_\lambda \kappa_t \) and then changing the first \( k \) coordinates by \( E \)) maps \( W \) onto a submodule \( W' \subseteq \bigoplus_{\lambda \in X} M^\lambda \).

For \( i \leq |X_0| \) denote by \( \text{pr}_i(W') \) the projection of \( W' \) on the \( i \)th copy of \( M^\mu \) in the direct sum; we assume that first \( k' := |X_2| \leq k \) coordinates corresponds to elements of \( X_2 \).

**Claim 2.** For \( i \leq k' \), we have \( \text{pr}_i(W') \supseteq S^\mu \) and, in fact,

\[
0 \oplus \cdots \oplus 0 \oplus S^\mu \oplus 0 \oplus \cdots \oplus 0 \subseteq W',
\]

with \( S^\mu \) in the \( i \)th position. For \( k' < i \leq k \) we have \( \text{pr}_i(W') \subseteq (S^\mu)^- \).

**Proof.** By the construction of \( E \), for \( i \leq k' \) the module \( W' \) contains the vector

\[
0 \oplus \cdots \oplus 0 \oplus e_t \oplus 0 \oplus \cdots \oplus 0
\]

with the polytabloid \( e_t \) in the \( i \)th position. This proves the first part of the claim. For the second part note that by the James submodule theorem
Let \( S^\mu \subseteq \text{pr}_i(W') \) or \( \text{pr}_i(W') \subseteq (S^\mu)^\perp \). If the former were the case, then a vector \( u \in W' \) would exist with \( \text{pr}_i(u) = e_i \), i.e., we would have \( \text{pr}_i(u\kappa_i) \neq 0 \), contradicting the maximality of \( X_2 \).

The map determined by \( E \) is clearly one-to-one, and both the map and its inverse are definable without parameters. This is because the map is a matrix of fixed size, so its entries from \( \mathbb{F}_p \) are explicitly given by the definition. Thus any generator set for \( W' \) can be pulled to \( W \) without extra parameters. We may thus assume without a loss of generality that \( W \) itself has the properties of \( W' \). Namely, there are \( k \geq 1 \) and \( k \geq k' \geq 0 \) such that:

1. For \( 1 \leq i \leq k' \), \( \text{pr}_i(W) \supseteq S^\mu \) and
   \[
   0 \oplus \cdots \oplus 0 \oplus S^\mu \oplus 0 \oplus \cdots \oplus 0 \subseteq W
   \]
   with \( S^\mu \) in the \( i \)th position.
2. For \( k' < i \leq k \), \( \text{pr}_i(W) \subseteq (S^\mu)^\perp \).

We now consider two cases, similar to the special case considered earlier. Case 1 is when \( k' \geq 1 \). Map \( W \) to a submodule \( U \) of

\[
\bigoplus_{\mu \in X_2} M^{\lambda_{i,v}} \oplus \bigoplus_{\lambda \in X \setminus X_2} M^\lambda,
\]

applying \( \eta \) to the first \( k' \) coordinates and the identity to all other coordinates (the ranges for \( i \) and \( v \) being as in the definition of \( \eta \)). Call this map \( \eta' \). Let \( Y \) be the multi-set of partitions so obtained. As \( Y \succ X \), by the induction assumption we have \( G' \subseteq U \) generating \( U \) such that any vector in \( G' \) is definable from a \( 2s^2d(Y) \)-tuple of parameters. Now, \( \text{Ker}(\eta') = S^\mu \oplus \cdots \oplus S^\mu \) and so

\[
\eta'^{(-1)}(G') \cup \{ 0 \oplus \cdots \oplus 0 \oplus S^\mu \oplus 0 \oplus \cdots \oplus 0 \mid S^\mu \text{ in the } i \text{th position, } i \leq k' \}
\]
generates \( W \). By parts 1 and 2 of Lemma 3.4 we can take a set \( H' \) consisting of a representative of each fiber of \( \eta' \) over \( G' \), and of a generator of each \( 0 \oplus \cdots \oplus 0 \oplus S^\mu \oplus 0 \oplus \cdots \oplus 0 \), such that all elements of \( H' \) are definable from a tuple of size \( 2s^2d(Y) + 2s^2 = 2s^2(d(Y) + 1) \leq 2s^2d(X) \). Then \( H' \) generates the same set as \( \eta'^{(-1)}(G') \cup S^\mu \oplus \cdots \oplus S^\mu \), which is \( W \). Moreover,

\[
|H'| \leq |G'| + k' \leq 2^{(r+2)s}2^{r^2 + d(Y)} + k' \leq 2^{(r+2)s}2^{r^2} + d(X).
\]

In Case 2 we have \( k' = 0 \), i.e., \( \text{pr}_i(W) \subseteq (S^\mu)^\perp \) for all \( i \in X_0 \). Let \( Y \) be the multi-set obtained by removing all \( \mu \)'s from \( X \) by the operation. Hence

\[
\bigoplus_{\lambda \in X} M^\lambda \text{ changes to }
\]

\[
\bigoplus_{\mu \in X_0} M^{\lambda_{i,v}} \oplus \bigoplus_{\lambda \in X \setminus X_0} M^\lambda,
\]

Let \( \rho' \) be the map

\[
\bigoplus_{\mu \in X_0} M^{\lambda_{i,v}} \oplus \bigoplus_{\lambda \in X \setminus X_0} M^\lambda \to \bigoplus_{\lambda \in X} M^\lambda,
\]
that applies the map $\rho$ (defined in the proof of the theorem) to each of the $|X_0| \bigoplus_{i,v} M^{\lambda \ast v}$-parts of $\bigoplus_{\xi \in Y} M_{\xi}$, and the identity to the other parts. Hence $\text{Rng}(\rho') = (S^0)^{\perp} \oplus \cdots \oplus (S^0)^{\perp} \bigoplus_{\lambda \in X \setminus X_0} M_{\lambda}$, and so if $G'$ generates $\rho'^{(-1)}(W)$, then $H' := \rho'(G')$ generates $W$. By the induction assumption and by Part 3 of Lemma 3.4, every vector in $H'$ is definable from tuples of size $2s^2d(Y) \leq 2s^2d(X)$.

Note that Lemma 3.4 requires that $|M| \geq |C \cup A| + 2s^2$; i.e., $|M| \geq |C| + 2s^1s^2$ suffices since we have $|A| \leq (2^s - 1)s^2$.

**Claim 3:** Let $H' \subseteq W \subseteq \bigoplus_{\lambda} M_{\lambda}$ be a set generating $W$ and having the following properties.

1. Every vector in $H'$ is definable from a $2s^1s^2$-tuple.
2. $|H'| \leq S$.

Then there is a uniform family $H$ that generates $W$ as a vector space and that is indexed by $(\lceil \log_2(S) \rceil + 1 + 2s^1s^2)$-tuples of support-size at most $2s^1s^2$.

**Proof.** To prove the claim note first that different vectors in $H'$ might be definable from the same index $i$ by different definitions, say by $A_{v,\lambda}(i,j)$ (where $v \in H'$, $\lambda$ is a coordinate, $j$ runs over indices corresponding to $\lambda$-tabloids, and $i$ the parameter index), while we need a single definition $B_\lambda(i_v,j)$ ($i_v$ an index of parameters from which $v$ is definable by $B$). Now, $B_\lambda$ defines the $F_{\mu}$-coordinate of the $\lambda$-tabloid $\text{tab}(j)$ in the $M_{\lambda}$-part of the direct sum. This is arranged as follows.

Take $\ell$ such that $2^{\ell - 1} \geq |H'|$. Any $\ell$-tuple $i = (i_1, \ldots, i_\ell)$ determines an $(\ell - 1)$-tuple of bits $i'_j \in \{0, 1\}^{\ell - 1}$ by $i'_j = 1$ if $i_j = j + 1$, and $i'_j = 0$ otherwise, for $j < \ell$. To different $v \in H'$ assign different $v^* \in \{0, 1\}^{\ell - 1}$ and define $B_\lambda(i,j) = (i'_v, i''_v)$, an $(\ell + 2s^1s^2)$-tuple, to be $A_{v,\lambda}(i''_v, j)$ if the support-size of $i'_v$ is $\leq 2$ and $i''_v = v^*$ and $i''_v = i'_v$, and identically zero otherwise.

Hence we have a single definition $B = (B_\lambda)_\lambda$ such that for any $v \in H'$ there is an $(\ell + 2s^1s^2)$-tuple $i$ of support-size $\leq 2s^1s^2$ such that $\text{pr}_{M_{\lambda}}(v)$ is definable by $B_\lambda$ from $i$. Now take $H$ to be the set of vectors defined by the same definition $B$, but with $i$ running over all possible $(\ell + 2s^1s^2)$-tuples. Clearly $H'$ generates every element of $H$, and $H$ is symmetric. So $H$ generates as a vector space the same module that $H'$ generates as a module, i.e., the module $W$. This proves the claim. \[\square\]

We can now complete the proof of the theorem. By the inductive construction we have a generating set $H'$ for $W$ satisfying the hypothesis of Claim 3 with $S \leq 2^{|\mu| + 2s^1s^2}$. Hence the required $H$ exists by Claim 3.

The systems $K^i$ are obtained as follows. The module $W$ is transformed in the construction (by $\eta$ or $\rho'^{(-1)}$) to submodules $W_u$ of $\bigoplus_{\lambda \in X} M_{\lambda}$, with $X_0, \ldots, X_m \succ \text{listing } X$. Denote by $y^u$ the tuples of variables indexed by
tabloid generators of $\bigoplus_{\lambda \in X_s} M^\lambda$. In particular, $x := y^{(0)}$ are variables indexed by $\mu$-tabloids. Hence, $x \in W$ iff there exist vectors $y^{(u)}$ in all $W_u$, $u = 0, \ldots, m - 1$, such that $\eta(y^{(u)}) = y^{(u+1)}$ or $y^{(u)} = \rho(y^{(u+1)})$ respectively. Any particular sequence of these equations gives one linear system $K^t$; an estimate for their number and for the number of parameters follows from Claim 1 in the same way as for systems $H^t$. \hfill \Box

We now address the issue of the constants $C$. Namely, the theory in [13, 12] which we use has been developed for $F_p[\text{Sym}(M)]$-moduli, while we use $F_p[\text{Sym}_C(M)]$-moduli. To see that this is, in fact, equivalent note that an $F_p[\text{Sym}_C(M)]$-module $M^\mu$, $\mu = (\mu_1, \ldots, \mu_h)$, is isomorphic to a direct sum of $F_p[\text{Sym}(M \setminus C)]$-moduli of the form $M^\lambda$, for all partitions $\lambda$ of $M \setminus C$ into $h$ rows such that $\lambda_i \leq \mu_i$ (all $i$), having one copy of $M^\lambda$ in the direct sum for any partition of $C$ into $h$ classes $C_1, \ldots, C_h$ of sizes $\mu_i - \lambda_i$. In particular, the copy of $M^\lambda$ in the sum corresponding to $\lambda$ and to the partitioning of $C$ into $C_1, \ldots, C_h$ represents the submodule of $M^\mu$ generated as a vector space by tabloids $T = (T_1, \ldots, T_h)$ such that $C_i \subseteq T_i$, for all $i$. Moreover, the isomorphism between the $F_p[\text{Sym}_C(M)]$-module and the direct sum clearly furnishes a translation between the definitions of elements.

The notions arising in the following lemma are defined in [13, 12]. We recall these definitions in the proof of the lemma.

**Lemma 3.4.** Let $\mu = (\mu_1, \ldots, \mu_{2^r})$ be a proper partition such that $\sum_{j \geq 2} \mu_j \leq s$. Assume $A \subseteq M$ and $|M| \geq |C \cup A| + 2s^2$.

1. Let $e_t \in S^\mu$ be any polytabloid from $M^\mu$. Then $\text{ind}(e_t)$ is definable from a $2s$-tuple.

2. Let $\psi_{i,v} : M^\mu \to M^{\lambda_i,v}$ be the linear maps from [13, Definition 17.10], and let $\eta := \bigoplus_{v=1}^{2^r-1} \bigoplus_{i=1}^{s-1} \psi_{i,v}$. Assume $s < p$. Let $w \in \text{Rng}(\eta) \subseteq \bigoplus_{i,v} M^{\lambda_i,v}$ be definable from $A$. Then there is $u \in \eta^{-1}(w) \subseteq M^\mu$ definable from some $A'$ such that $|A' \setminus A| \leq 2s^2$.

3. Let $\varphi_{i,v} : M^{\lambda_i,v} \to M^\mu$ be the linear maps from [12], denoted by $\psi_{i,-v}$ there. Let $\rho := \sum_{i,v} \varphi_{i,v} \circ \text{pr}_{\lambda_i,v}$ (with the same range for $i, v$ as in Part 2), and let $w \in \bigoplus_{i,v} M^{\lambda_i,v}$ be definable from $A$. Then $\rho(w)$ is also definable from $A$.

**Proof of Part 1.** Assume that $\mu = (\mu_1, \mu_2, \ldots, \mu_{2^r})$. By [13, 4.5] $S^\mu$ is generated by any one polytabloid $e_t$. Here $t$ is some tableau (defining the tabloid $\{t\}$) and $e_t = \{t\} \kappa_t$, where $\kappa_t = \sum_{\pi \in C_t} \sgn(\pi) \pi$ is the signed column sum. $C_t$ is the subgroup of $\text{Sym}_C(M)$ that fixes set-wise all columns of $t$.

Consider the elements of the first $s$ columns of $t$ (there are $\leq 2s$ such elements) as a parameter $2s$-tuple $i = (i_1, \ldots, i_{2s})$. We may think of it as...
defining a tableau $t_i$ with $2^r$ rows

$$(i_1, \ldots, i_s, X), \ (i_{s+1}, \ldots, i_{s+\mu_2}), \ \ldots, \ (i_{s+\sum_{2\leq j \leq 2^r-1} \mu_j}, \ldots, i_{s+\sum_{2\leq j \leq 2^r} \mu_j}),$$

where $X$ is an arbitrary ordering of $M \setminus \text{supp}(i)$. The ordering of $X$ is, in fact, irrelevant as $\kappa_i$ depends only on $i$ (only the first $s$ columns of $t_i$ can be non-trivial). The column stabilizer group $C_{t_i}$ is a finite subgroup of the symmetric group of $\text{supp}(i)$ of size depending on $s$, and hence the signed column sum $\kappa_i$ can be listed explicitly (using $i$ as parameters).

Denote by $v_i$ the vector obtained from $e_{t_i}$ by the $\text{ind}$–operation. As any $e_{t_i}$ generates $S^\mu$, $v_i$ generates $\text{ind}(S^\mu)$, and the uniform system $\{v_i\}_i$ generates $\text{ind}(S^\mu)$ as a vector space. \hfill \square

**Proof of Part 2.** The map $\eta$ is the direct sum of some maps $\psi_{i,v_i}$, $1 \leq i < 2^r$, $0 \leq v < \mu_{i+1}$ (cf. [13, Definition 17.10]). The map $\psi_{i,v}$ maps $M^\mu$, $\mu = (\mu_1, \ldots, \mu_{2^r})$, to $M^{\lambda^+, v}$, $\lambda^+ = (\mu_1, \mu_2, \ldots, \mu_{i-1}, \mu_i + \mu_{i+1} - v, v, \mu_{i+2}, \ldots, \mu_{2^r})$, by sending a $\mu$–tabloid $T$ to $\sum \{T' \mid T' \in X_T\}$, where $X_T$ is the set of all $\lambda^+, v$–tabloids $T'$ that agree with $T$ on all rows except for the $i$th and the $(i + 1)$st rows, and the $(i + 1)$st row of $T'$ is a subset of size $v$ of the $(i + 1)$st row of $T$.

We shall utilize certain moduli $S^{\mu^*, \mu}$, similar to the proof of [2, Lemma 35]. Let $(\mu^*, \mu)$ be a pair of partitions with $2^r$ rows such that $\mu^*_1 = \mu_1$ and $\mu^*_i \leq \mu_i$ for all $i$, and such that $\mu^*$ is also proper (and hence a partition of an integer not greater than $N$). Let $C^*_i$, where $t$ is a $\mu$–tableaux, be a subgroup of $C_i$ which fixes point-wise all elements of $t$ outside $\mu^*$. Let $S^{\mu^*, \mu}$ be the module spanned by all $e^{\mu^*, \mu}_{t} := \{t\} \{\sum_{\pi \in C^*_t} \text{sgn}(\pi) \pi\}$. Note that $e^{0, \mu}_t = \{t\}$ (where $0$ is the partition with all rows except the first empty) and $e^{\mu^*, \mu}_t = e_{t_i}$, so $S^{0, \mu} = M^\mu$ and $S^{\mu^*, \mu} = S^\mu$. (These modules are defined in [13, Definitions 17.2 and 17.4].)

Assume $\mu^* \neq \mu$ and that $i > 1$ is the first row such that $\mu^*_{i-1} = \mu_{i-1}$ but $\mu^*_i \neq \mu_i$. Define (see [13, Definition 15.10]) two new pairs as follows:

1. Pair $(\mu^*, \mu R_i)$: change $\mu_1$ to $\mu^*_1$ and $\mu_{i-1}$ to $\mu_{i-1} + \mu_i - \mu^*_i$.
2. Pair $(\mu^* A_i, \mu)$: change $\mu^*_i$ to $\mu^*_i + 1$ if $\mu^*_i + 1 \leq \mu_{i-1}$; otherwise let the new pair be $(\mu^* A_i, \mu) := (0, 0)$.

These operations also make sense for $\mu$–tableaux. Here $t R_i$ is $t$ with the $\mu_i - \mu^*_i$ elements of the $i$th row of $t$ that are outside $\mu^*_i$ moved to the end of the $(i - 1)$st row.

The crucial facts (see [13, Theorem 17.13]) are that $S^{\mu^*, \mu} \psi_{i-1, \mu^*_i} = S^{\mu^*, \mu R_i}$ and $S^{\mu^*, \mu} \cap \text{Ker}(\psi_{i-1, \mu^*_i}) = S^{\mu^*, A_i, \mu}$. This will link these moduli with the map $\eta$. Map $\psi_{i-1, \mu^*_i}$ affects only two rows of a tabloid. Thus the following claim can be rephrased (and proved) as a statement about hyper-graphs. We shall follow, however, a more direct approach, related to [2, Lemma 35].
Claim 1. Let \( u' \in S^{\mu^*, \mu R_i} \) be definable over \( A \) and assume that \( u' = \psi_{\nu_{t-1}, \mu^*}(\omega) \) for some \( \omega \in S^{\mu^*, \mu} \). Assume \( p > s \). Then there is \( \omega \in S^{\mu^*, \mu} \) definable over some \( A' \supseteq A \) such that \( u' = \psi_{\nu_{t-1}, \mu^*}(\omega) \) and \( |A' \setminus A| \leq 2s \).

Proof. We are going to use the identity (for a \( \mu \)-tableaux \( t \))

\[
\psi_{\nu_{t-1}, \mu^*}(e_t^{\mu^*, \mu R_i}) = e_{\nu_{t-1}, \mu R_i}
\]

from [13, Lemma 17.12, p. 68]. We first need to discuss the encoding of polytabloids \( e_t^{\mu^*, \mu} \) by indices. In particular, encode \( e_t^{\mu^*, \mu} \) by an index, denoted by \( \nu_{t}(t, \mu^*, \mu) \),

\[
\xi = (\text{ind}(\{t\}), \xi_1, \ldots, \xi_{\mu_2})
\]

where the tuple \( \text{ind}(\{t\}) \) is extended by sets \( \xi_j \), the sets of elements of \( t \) in the \( j \)th column that are inside \( \mu^* \). This generalizes the encoding of both \( e_i \) (\( = e_{i}^{\mu^*, \mu} \)) and \( \{t\} \) (\( = e_{\{t\}}^{0, \mu} \)) with the following modification. Namely, all codes \( \xi \), as well as the codes for the \( e_i \)'s list the first \( \mu_2 \) elements of the first row (which are all in \( \mu^* \) as \( \mu_1^* = \mu_1 \)), while \( j = \text{ind}(\{t\}) \) does not. To remedy this, let \( A' \supseteq A \) be a set of \( 2s \) new constants not in \( A \cup C \). To get from \( j \) a code \( \xi \) for \( e_{\{t\}}^{0, \mu} \) pick first (in some fixed ordering of \( A' \) \( \mu_2 \) elements of \( A' \) not occurring in \( \text{supp}(j) \cup A \cup C \) and place these into the first row. As \( \mu_2 \leq s \) and \( |\text{supp}(j)| \leq s \), this is always possible. Clearly, \( \text{ind}(e_{\{t\}}^{0, \mu}) = j \).

Note that two tableaux \( t, t' \) yield the same code \( \xi \) iff they differ only in the ordering of the rows outside \( \mu^* \), i.e., iff \( e_t^{\mu^*, \mu} = e_{t'}^{\mu^*, \mu} \). We shall denote such polytabloids \( e_t^{\mu^*, \mu} \). Also, \( I(t, \mu^*, \mu) \) determines \( I(t'R_i, \mu^*, \mu) \). We denote these codes sometimes by \( \xi R_i \). Such \( \xi \) need not to be unique, but their number \( (\mu_1 - \mu_1^* + \mu_i - \mu_i^*) \) is non-zero modulo \( p \) (as \( s < p \)) and so we can take all \( \xi \)'s with an appropriate weight in \( F_p \).

Let \( T' \) be a \( \mu R_i \)-tableloid with \( j' = \text{ind}(T') \). Let \( \xi' := \xi R_i \) be a code of a \( (\mu^*, \mu R_i) \)-tableloid \( e_{\xi'}^{\mu^*, \mu R_i} \). The coefficient of \( T' \) in \( e_{\xi'}^{\mu^*, \mu R_i} \) depends only on \( \text{tp}(j', \xi') \). Hence, if \( u' = \sum_T a_T T' \) is from \( S^{\mu^*, \mu R_i} \) with \( a_T \) definable over \( A \), there are \( b_{\xi'} \) definable over \( A' \) such that \( u' = \sum_{\xi'} b_{\xi'} e_{\xi'}^{\mu^*, \mu R_i} \).

Using the identity mentioned earlier, we have

\[
\psi_{\nu_{t-1}, \mu^*}(\sum_{\xi} b_{\xi} e_{\xi}^{\mu^*, \mu R_i}) = \sum_{\xi'} b_{\xi'} e_{\xi'}^{\mu^*, \mu R_i} = u'
\]

with \( b_{\xi} := b_{\xi R_i} \). It remains to show that \( a_T \), with \( T \) ranging over \( \mu \) -tableloids such that \( \sum_T a_T T = \sum_{\xi} b_{\xi} e_{\xi}^{\mu^*, \mu R_i} \), is definable over \( A' \). The value \( b_{\xi} \) depends only on \( \text{tp}(\xi / A') \) and the coefficient of \( T \) in \( e_{\xi}^{\mu^*, \mu R_i} \) only on \( \text{tp}(\text{ind}(T), \xi / A') \).

Moreover, by Lemma 1.7, the number of \( \xi \) with a given type over \( A' \) depends only on \( |M| \) mod \( p^\nu \), for some \( \nu \geq 1 \), provided \( M \) is at least as large as the support-size of the type \( \text{tp}(\xi / A') \) (which is the case, by the hypothesis \( |M| \geq |A \cup C| + 2s^2 \) of the lemma). Thus the \( a_T \) are definable over \( A' \) as well,
with possibly different definitions for each remainder class of $|M|$ mod $p'$. 
(This argument is similar to Part 3 of the proof of the lemma.) This yields the claim. 
\[ \square \]

Let $\mu^1, \ldots, \mu^k$ be the sequence of proper partitions

\[(\mu_1, 0, \ldots, 0), (\mu_1, 1, 0, \ldots, 0), \ldots, (\mu_1, \mu_2, 0, \ldots, 0),
\]

\[(\mu_1, \mu_2, 1, 0, \ldots, 0), \ldots, (\mu_1, \mu_2, \ldots, \mu_{2^r})
\]

obtained by filling $(\mu_1, 0, \ldots, 0), \ldots, (\mu_1, \mu_2, \ldots, \mu_{2^r})$ with 0

etc. Note that $\mu$ obtained by filling $(\mu_1, 0, \ldots, 0)$ to $\mu$ first in the 2nd row, then in the 3rd row, etc. Note that $k \leq s$.

Let $\psi^1, \psi^2, \ldots$ be the sequence of maps

\[ \psi_{1,0}, \psi_{1,1}, \ldots, \psi_{1,\mu_2-1}, \psi_{2,0}, \psi_{2,1}, \ldots, \psi_{2,\mu_3-1}, \ldots, \psi_{r-1,\mu_{2^r}-1}, \]

up to $\psi_{j_0,0}, \ldots, \psi_{j_0,\mu_{j_0+1}-1}$, where $j_0$ is the last row $j$ such that $\mu_{j+1} > 0$.

Fix any $u \in M^\mu = S^{0,\mu}$ such that $\eta(u) = w$. Assume that $w$ is defined over $A$. We are going to modify $u$ suitably.

Claim 2: For any $j \geq 1$ there is $v_j \in M^\mu$ with the following properties:

1. $v_j$ is definable over some $A^j \supseteq A$ such that $|A^j \setminus A| \leq j \cdot 2s$.
2. For all $i \leq j$ we have $\psi^i(u) = \psi^i(v_j)$.

Proof. The claim is proved by induction on $j$. If $j = 1$ take $w' := u$ to be the projection of $w$ on $M^{\lambda^0}$.

So $w' = \psi_{1,0}(u) = \psi^1(u) \in M^{\lambda^0}$

is also definable from $A$. Apply Claim 1 with $u' := u$ and $w' := \psi_{1,0}(u)$ and let $v_1$ be the $w$ provided by this claim.

Assume the claim holds for $j$. To prove that it holds for $j + 1$ take $u_j := u - v_j$ and note that as $\psi^i(u) = \psi^i(v_j)$ for all $i \leq j$, we have $u_j \in \bigcap_{i \leq j} \Ker(\psi^i)$.

By the definition of the sequences $\mu^1, \mu^2, \ldots$ and $\psi^1, \psi^2, \ldots$ and by the theorem mentioned earlier ([13, Theorem 17.13]), $\bigcap_{i \leq j} \Ker(\psi^i) = S^{\mu^{j+1},\mu}$.

We want $v_{j+1} \in M^\mu$ such that $\delta := v_{j+1} - v_j \in S^{\mu^{j+1},\mu}$, and $\psi^{j+1}(v_{j+1}) = \psi^{j+1}(u)$ (as then also, for all $i \leq j$, $\psi^i(v_{j+1}) = \psi^i(v_j + \delta) = \psi^i(v_j) = \psi^i(u)$).

Note that $\psi^{j+1}(u)$ and $\psi^{j+1}(v_j)$ are defined over $A^j$ (analogous to Part 3), so the same holds for $w' := \psi^{j+1}(u - v_j)$. Apply Claim 1 with $u' := u_j \in S^{\mu^{j+1},\mu}$. The claim gives $\delta \in S^{\mu^{j+1},\mu}$ definable over some suitable $A' \supseteq A^j$.

Hence $v_{j+1} := v_j + \delta$ is definable over $A^{j+1} := A'$ as well and has the required properties.

Now take $v_k \in M^\mu$, where $k$ is the length of the sequence of $\psi$'s. By Claim 2, $\psi^i(v_k) = \psi^i(u)$ for all $i$, so

$\eta(v_k) = \eta(u) = w$

and $v_k$ is defined over $A^k$ with $|A^k \setminus A| \leq k \cdot 2s \leq 2s^2$. This proves Part 2 of the lemma.
\[ \square \]
Proof of Part 3. The maps \( \varphi_{i,v} : M^{\lambda_i,v} \to M^\mu \) are defined as follows. (In [12] these maps are denoted by \( \psi_{i,-v} \); we use the other notation to avoid confusion with the \( \psi \)'s from Part 2.) The map \( \varphi_{i,v} \) maps a \( \lambda_i,v \)-tabloid \( T \) to \( \sum_{T' \in X_T} T' \), where \( X_T \) is the set of all \( \mu \)-tabloids agreeing with \( T \) in all except the \( i \)th and the \( (i+1) \)st rows, with the \( (i+1) \)st row of \( T \) together with some \( \mu_{i+1} - v \) elements of the \( i \)th row of \( T \).

Assume now that \( w \in \bigoplus_{i,v} M^{\lambda_i,v} \) is a vector defined over \( A \). Write \( w \) as the sum of its \( M^{\lambda_i,v} \)-parts, \( w = \sum_{i,v} w_{i,v} \) and write a particular \( w_{i,v} \) as \( w_{i,v} = \sum_T c_T T \) with \( T \) running over \( \lambda_i,v \)-tabloids. Then

\[
\varphi_{i,v}(w_{i,v}) = \sum_T c_T \varphi_{i,v}(T) = \sum_T c_T \left( \sum_{T' \in X_T} T' \right),
\]

where \( X_T \) are the \( \mu \)-tabloids occurring in the definition of \( \varphi_{i,v}(T) \), and this equals to

\[
\sum_{T'} \sum_{T' \in X_T} c_T \cdot T'.
\]

The possible sets \( X_T \) depend on \( T' \) and the types of some suitable \( T \) (and their multiplicities) depend on the type of \( T' \). Thus the \( F_p \)-value in [...] depends only on \( \text{tp}_c(T'/A) \), by Lemma 1.7, for any particular remainder class of \( N \) modulo \( p^r \). To apply Lemma 1.7 we need \( |M| \) to be at least equal to the support-size of \( \text{tp}_c(T'/A) \), i.e., at least \( |C \cup A| + s \). (Note that this gives different definitions for \( \varphi_{i,v}(w_{i,v}) \) for different remainder classes.) This proves Part 3 of the lemma. \( \square \)

We now derive an effective version of Ajtai’s theorem (see Theorem 2.3) from Theorem 3.3. (It is clear that the generating set \( H' \) constructed in the proof of Theorem 3.3 satisfies the conditions imposed on \( G \) in Theorem 3.1, so we obtain this theorem as well.) We restate the theorem (the equivalence of its parts 1 and 3) as we incorporate the bounds. The proof follows the original proof of [2] except that we use our Theorem 3.3 in place of Theorem 3.1.

**Theorem 3.5.** Let \( L(C) \) and \( k, \ell, s, z \geq 1 \) be given. Assume that a family \( F \) is a uniform family indexed by \( \ell \)-indices \( i \) of support-size \( \leq z \) of linear polynomials \( F_i \) with variables indexed by \( k \)-indices of support-size \( \leq s \). Then there exists \( \nu \geq 1 \) (depending only on \( |C| \), \( z \), \( s \) and tacitly on \( p \)) and a set

\[
\text{...}
\]
such that for every \( M \) such that \(|M| \geq |C| + 2z + 2^{s+1}s^2 + s\) the following two statements are equivalent:

1. The system \( \{ F^M_i = 0 \}_{i} \) is solvable in \( \mathbb{F}_p \).
2. \(|M| \equiv r \mod p^\nu\) for some \( r \in \mathbb{Q} \).

Proof. Let \( F \) be a family of linear equations satisfying the hypothesis of the theorem. Let \( i_0 \) be an index such that \( F_{i_0} \) has a non-zero absolute coefficient \( c_{i_0} \). (If all \( F_i \) are homogeneous there is nothing to prove as \( F = 0 \) has the trivial solution.) By replacing any \( F_i \) by \( F_i - c_i F_{i_0} c_{i_0}^{(-1)} \), where \( c_i \) is the absolute coefficient of \( F_i \), we may assume without loss of generality that all equations of \( F \) are homogeneous, except for \( F_{i_0} \). To maintain the uniformity of the system, we add \( \text{supp}(i_0) \) to \( C \).

Now consider two homogeneous systems \( F^1 \) and \( F^2 \). System \( F^1 \) is obtained from \( F \) by deleting the equation \( F_{i_0} = 0 \); system \( F^2 \) is obtained by changing its absolute coefficient to zero. Denote by \( V(F^1) \), \( V(F^2) \) the sets of \( \mathbb{F}_p \)-solutions of these systems. As both systems are homogeneous, the sets are vector spaces. As both systems are uniform, the sets are symmetric with respect to \( \text{Sym}_C(M/\text{supp}(i_0)) \), and thus are \( \mathbb{F}_p \text{Sym}_C(M/\text{supp}(i_0)) \)-moduli.

Clearly, \( F \) has a solution iff \( V(F^2) \not\subseteq V(F^1) \). By Theorem 3.3, for \(|M| \geq |C| + z + 2^{s+1}s^2 \geq |C \cup \text{supp}(i_0)| + 2^{s+1}s^2 \), this is equivalent to the statement that there is a vector \( v \in M^{(k)} \) such that

1. \( v \) is a solution of \( F^1 = 0 \).
2. \( v \) is not a solution of \( F^2 = 0 \).
3. \( v \) is definable from a \( 2^{s+1}s^2 \)-tuple.

To prove this, we first note that there are only finitely many \( v \) satisfying the last condition, so the entire statement is finite. It is enough to show that for any particular definition of a vector \( v \) satisfying 3, whether or not the vector defined by the definition also satisfies the first two conditions depends only on \(|M| \mod p^\nu\), for some suitable \( p^\nu \).

This is verified via Lemma 1.8. Let \( f \in F^1 \) be a linear polynomial defined from an \( \ell \)-index of support-size \( \leq z \) (over \( \text{supp}(i_0) \)). By Lemma 1.8, whether or not \( v \) satisfies \( f = 0 \) depends only on \( p^\nu \), provided \(|M| \geq |C| + z + z + 2^{s+1}s^2 + s \) (where \(|C| + z \) is the bound for \(|C \cup \text{supp}(i_0)| \), \( z \) for parameters of \( f \), \( 2^{s+1}s^2 \) for the parameters of \( v \), and \( s \) for the indices of the variables). This proves Theorem 3.5.

Note that the same argument yields also an upper bound for \( \nu \); however, we do not need this bound.

4. Moduli of polynomials with bounded degree PC-proofs

In the remainder of this paper let \( F \) be a fixed uniform family of polynomials of degree at most \( d \) with variables indexed by \( k \)-ary indices, \( k \geq 1 \), which is
indexed by indices of support-size at most $2^{k^2 d + 1} (k^2 d)^2$, and which contains the family $\text{COMM}^k$.

**Definition 4.1.** For $t \geq d$, $PC_t(M, F)$ is the vector space over $F_p$ consisting of polynomials from $\text{Poly}(M, k, t)$ that have a PC–proof from $F_M$ of degree at most $t$.

We are going to show (in the proof of Theorem 5.1) that the property of $M$ that $g^M \in PC_t(M, F)$, where $g$ is a uniformly defined polynomial, depends only on the cardinality of $M$ modulo some other fixed power $p^{\nu}$, provided $M$ is large enough.

**Lemma 4.2.** Let $H$ and $H'$ be uniform families of vectors indexed by $r$–indices of support-size at most $s$ and such that both $H$ and $H'$ are indexed by indices of support-size at most $z$. Then there exists $\nu \geq 1$ (depending only on $|C|$, $z$, $s$ and tacitly on $p$) and a set $Q \subseteq \{0, \ldots, p^\nu - 1\}$ such that for every $M$ such that $|M| \geq |C| + 2(z + s) + 2^{z+1} z^2 + z$ the following two statements are equivalent:

1. $H' \subseteq \text{Span}_{F_p}(H^M)$.
2. $|M| \equiv r \mod p^\nu$ for some $r \in Q$.

**Proof.** For uniform families $H$ and $H'$ there is a uniform family of linear equations which has a solution in $F_p$ for a finite $M$ iff $H' \subseteq \text{Span}_{F_p}(H^M)$. The system contains for any pair $(i', j)$ of an index $i'$ of $H'$ and an index $j$ of a coordinate of a vector, an equation with variables $y_i$ indexed by indices $i$ of $H$, such that $H'(i', j) = \sum_i y_i H(i, j)$.

By Theorem 3.5, whether or not the system has a solution over $M$, for $M$ of size at least $|C| + 2(z + s) + 2^{z+1} z^2 + z$ (with the parameter $z$ in Theorem 3.5 being $z := z + s$ and $s := z$) depends only on $r < p^{\nu}$ such that $|M| \equiv r \mod p^{\nu}$.

The following theorem is the only part of the lower bound proof for PC using the specific definition of $PC_t(M, F)$.

**Theorem 4.3.** There exists a number $\nu \geq 1$ (depending only on $k$ and $t$) and uniform families $H^r$, $r = 0, 1, \ldots, p^{\nu} - 1$, of polynomials of degree at most $t$, with variables indexed by $k$–ary indices, indexed by indices of support-size $\leq 2k^2 t + 1 (k^2 t)^2$, such that the following holds: For every finite $M$, if $|M| \equiv r \mod p^{\nu}$ and $|M| \geq |C| + 6^{k^2 t}$, the system $(H^r)^M$ generates as a vector space the space $PC_t(M, F)$.

**Proof.** A submodule $W$ of $\text{Poly}(M, k, t)$ is equal to $PC_t(M, F)$ iff $W$ is the smallest subspace containing $F^M$ and closed under the multiplication rule of
PC. In particular, the latter condition can be formulated as follows: if \( g \in W \) and \( \deg(g) < t \) then \( x \cdot g \in W \), for all variables \( x \).

Since of \( \text{COMM}^k \) is contained in \( F \), this reflects PC in commutative polynomial rings.

Monomials of degree \( \leq t \) in \( \text{Var}(M, k) \) are indexed by indices of support-size \( \leq k^2t \). By Theorem 3.3 there is \( c \geq 1 \) such that any submodule of \( \text{Poly}(M, k, t) \) is generated as a vector space by one of the uniform families \( (H^t)^M \), for some \( t \leq c \), with \( H^t \) indexed by indices of support-size \( \leq 2^{k^2t+1}(k^2t)^2 \).

For a pair of uniform families \( H' \) and \( H \) from this finite list consider the following conditions:

1. \( F \subseteq \text{Span}_{F_p}(H) \).
2. \( H' \) consists only of polynomials of degree less than \( t \).
3. \( H' \subseteq \text{Span}_{F_p}(H) \).
4. \( H \) consists only of polynomials of degree at most \( t \).
5. \( x_i \cdot H' := \{ x_i g \mid g \in H' \} \subseteq \text{Span}_{F_p}(H) \), for all variables \( x_i \).
6. \( \text{Span}_{F_p}(H^M) \cap \text{Poly}(M, k, t - 1) \subseteq \text{Span}_{F_p}(H^M) \).
7. \( \text{Span}_{F_p}(H^M) \) is the smallest subspace of \( \text{Poly}(M, k, t) \) among all spaces \( \text{Span}_{F_p}(H'^M) \), for all pairs of uniform families generating sets \( H'' \), \( H'' \) satisfying the above six conditions.

Denote the condition that \( H'^M \subseteq \text{Span}(H^M) \) by \( \Psi_{H', H} \). By Lemma 4.2 (with \( z := 2^{k^2t+1}(k^2t)^2 \) and \( s := k^2t \)), whether or not \( \Psi_{H', H} \) is true in \( M \) depends only on \( M \mod p^\nu \), for some fixed \( \nu \geq 1 \), provided \( M \geq |C| + 2(z + s) + 2^{k^2} + z \). (Hence \( M \geq |C| + 6^{k^2} + 2 \) suffices.)

\[ \text{For } M \geq |C| + 6^{6^{k^2}}, \text{ whether or not } M \text{ satisfies } \Phi_H \text{ depends only on } r < p^\nu \text{ such that } |M| \equiv r \mod p^\nu. \]

By Theorem 3.3, for every \( r \) there is at least one \( H^t \) such that \( \Phi_{H^t} \) is true in \( M \) if \( |M| \equiv r \mod p^\nu \) and \( |M| \geq |C| + 6^{k^2} \geq |C| + 2^{k^2+1}(k^2t)^2 \), i.e., \( (H^r)^M \) generates as a vector space \( \text{PC}_l(M, F) \) for all such \( M \).
Note that we cannot expect to find one uniform family generating as a vector space $PC_t(M, F)$ for all $M$. Indeed, the example of a linear system $F$ consisting of the equations $\{x_i - 1 = 0\}_{i \in M}$ together with the equation $\sum_{i \in M} x_i = 0$ demonstrates this, as solvability of $F^M$ is equivalent to $1 / p \in PC_1(F, M)$.

5. Degree lower bounds

For a uniform system $F$ denote by $F^{(-)}$ the system without the polynomial $F^{\emptyset}$. It is also uniform. We continue to assume that $F$ satisfies the conditions stated at the beginning of Section 4.

Theorem 5.1. Let $F$ be a uniform family as above. Then for every $t \geq d$ there is $\nu \geq 1$ such that the following holds for every $r < p^\nu$:

If there is at least one $M$ with $|M| \geq |C| + 6^k 2^z$ such that $|M| \equiv r \mod p^\nu$ and

$F^{\emptyset}_M \notin PC_t(M, F^{(-)})$,

then for no $M$, $|M| \geq |C| + 6^k 2^z$ and $|M| \equiv r \mod p^\nu$, is there a PC-proof of degree at most $t$ of $F^{\emptyset}_M$ from $F^{(-)}_M$.

Proof. Let $H^r$ be the uniform families of generating sets for $PC_t(M, F^{(-)})$ (generating this space as a vector space) guaranteed by Theorem 4.3 if $|M| \geq |C| + 6^k 2^z$. The systems $H^r$ are indexed by indices $i$ of support-size $\leq 2^k t + 1 (k^2 t)^2$, and the monomials correspond to indices $j$. Hence we may write

$H^r_i = \sum_j H^r(i, j) x^j$.

Now take variables $y_i$ indexed by the $i$’s and consider the system of linear equations

$F(\bar{0}, j) - \sum_i H^r(i, j) y_i = 0$

This system, say $K^r$, is obviously also uniform. It is indexed by $j$’s of support-size $z \leq k^2 t$, and the variables are indexed by $i$’s of support-size $s \leq 2^{k^2 t + 1}(k^2 t)^2$. Moreover, for any $M$ such that $|M| \equiv r \mod p^\nu$, we have $F^\emptyset_M \in PC_t(M, F^{(-)})$ iff $K^M_r$ has a solution in $F^\emptyset_p$.

Thus Theorem 3.5 completes the proof, provided

$|M| \geq |C| + 6^k 2^z \geq |C| + 2z + 2^{z+1}s^2 + s$.

□

The following corollary is immediate.
Corollary 5.2. Let $F$ be a uniform family as above. Assume that for every $\nu \geq 1$ and every $r < p^\nu$ there is an arbitrarily large $M$ such that $|M| \equiv r \mod p^\nu$ and such that there is a solution in $\mathbb{F}_p$ of the system $F^{(-),M}$ not satisfying $F^{M,\emptyset} = 0$.

Then $F^{M,\emptyset}$ does not admit a PC–proof of degree $t \leq \log_6(|M \setminus C|)/k^2$ from $F^{(-),M}$.

This yields a lower bound for $(N,m)$–systems.

Corollary 5.3. Let $p$ be fixed, and let $m \geq 1$ be not divisible by $p$. Then, for any $N$ not divisible by $m$, there is no PC–refutation of the $(N,m)$–system of degree $t \leq \log_6(\log_6(2^k))/m$.

Proof. Take any $\nu \geq 1$ and $r < p^\nu$. As $p$ does not divide $m$, there are arbitrarily large $N$ divisible by $m$ such that $N \equiv r \mod p^\nu$. The $(N,m)$–system has a solution for such $N$, however. Hence the ideal generated by it is non-trivial, i.e., 1 is not derivable from the system, and Corollary 5.2 applies.

We show now that a merely non-constant degree lower bound for PC–proofs of the $(N,m)$–systems follows already from Corollary 3.2 and the non-constant degree lower bound for NS–proofs of the same system proved in [4]. In fact, such a reduction applies in general.

Definition 5.4. For $t \geq d$, $NS_t(M,F)$ is the vector space over $\mathbb{F}_p$ consisting of polynomials $g$ of degree $\leq t$ with variables from $\text{Var}(M,k)$ that have an NS–proof from $F^M$ of degree at most $t$, i.e., such that there are polynomials $G_i$ with variables from $\text{Var}(M,k)$, for which

$$g = \sum_i G_i F^M_i$$

and $\deg(G_i F^M_i) \leq t$ for all $i$.

Theorem 5.5. For every $k,t$ there is $t'$ such that for any $F$ as in Theorem 5.1 the following holds for all $M$:

If $F^M \in PC_t(M,F^{(-)})$ then $F^M \in NS_{t'}(M,F^{(-)})$.

In particular, if the $F^M$ (where $M$ is a parameter) do not admit constant-degree NS–proofs from $F^{(-),M}$, they do not admit constant-degree PC–proofs either.

Proof. Consider the $\mathbb{F}_p[\text{Sym}_C(M)]$–module $\text{Poly}(M,k,t)$, which is a submodule of some $M^{(kt)}$. Take the constant $c \geq 1$ guaranteed by Corollary 3.2 for $r := kt$. 
Let $W_u$ for $u = t, t+1, \ldots$ be the module of polynomials from $NS_u(M, F)$ that have degrees $\leq t$. As $u$ increases, $W_u$ does not decrease. We claim that if for some $t'\in \mathbb{N}$

$$W_{t'} = W_{t'+1},$$

then $PC_t(M, F) \subseteq W_{t'}$. To see this, take $f \in W_{t'}$ of degree $< t$. Then its multiple $xf$ by a variable $x$ is in $W_{t'+1} = W_{t'}$. Hence $W_{t'}$ is closed under the PC-rules, and as it contains $F^M$ the claim follows.

Now note that, since there are at most $c$ different submodules of $\text{Poly}(M, k, t)$, some $t' < t + c$ has the above property.

Note that the theorem yields also non-constant PC-lower bounds for the systems encoding the pigeonhole principle (see, e.g., [3, 21]). A linear lower bound was proved in [21]. (Another proof of non-constant lower bound is in [18].)

Finally we note that the same method yields $\Omega(\log(N))$ lower bounds for Nullstellensatz proofs. The difference allowing to save one log is the following. The space $PC_t(M, F)$ is a span of one of the systems $H^t$, each indexed by indices of support-size $O(2^t)$. The space $NS_t(M, F)$ is, however, described as a span of one system $H$ indexed by indices of support-size $\mathcal{O}(t)$ only. Namely, for every $F_i$ and every monomial $x_j$ such that $\deg(x_jF_i) \leq t$ the family $H$ contains the polynomial $H_{j,i} := x_jF_i$ indexed by $(j, i)$ of support-size $O(t)$. Hence in the proof of Theorem 5.1 the parameter $s$ is $O(t)$ and the assumption $M \geq |C| + 6^{k^2t}$ suffices, and we have the following theorem (after Corollary 5.2).

**Theorem 5.6.** Let $F$ be a uniform family as above. Assume that for every $r \geq 1$ and every $r < p^r$ there is an arbitrarily large $M$ such that $|M| \equiv r \mod p^r$ and such that there is a solution in $F_{p\cdot r}$ of the system $F^(-)M$ that does not satisfy $F_{p\cdot r} = 0$.

Then $F^M$ does not admit an NS-proof of degree $t \leq \log_6(|M \setminus C|)/k^2$ from $F^(-)M$.

### 6. An example with primality

The question about the length of proofs of propositionally encoded primality of a number was raised in [19] (in connection with effective interpolation). This is an important problem as such tautologies are currently the only reasonable candidates for tautologies hard for the usual Hilbert-style systems (the so-called Frege systems, or even for Extended Frege systems). The numbers are encoded in binary there rather than in unary as is done here. However, until now, no lower bounds (even conditional bounds, assuming some unproven complexity-theoretic conjecture of a general nature) for any proof system were known for either formulation.
We define a uniform system of polynomials $\Pi$ such that $\Pi^M$ is solvable only if the cardinality $|M|$ is composite.

**Definition 6.1.** Let $M$ be an $L(C)$-structure, $C = \{c\}$. The variables of the system $\Pi^M$ are $x_i, y_j$ for $i, j \in M \setminus C$ and $z_{ijk}$ for $i, j \in M \setminus C$ and $k \in M$. The polynomials of $\Pi^M$ are

1. $w^2 - w$ for all variables $w = x_i, y_j, z_{ijk}$.
2. $x_i y_j (1 - \sum_k z_{ijk})$ for all possible $i, j$.
3. $1 - \sum_{i,j} x_i y_j z_{ijk}$ for all possible $k$.
4. $x_i x_{i_1} y_j y_{j_1} z_{i_{i_1}j_{j_1}k} z_{i_{i_2}j_{j_2}k}$ for all possible $i_1, i_2, j, j_1, j_2, k$ if $i_1 \neq i_2$ or $j_1 \neq j_2$.
5. $x_i y_j z_{ijk_1} z_{ijk_2}$ for all possible $i, j, k_1, k_2$ if $k_1 \neq k_2$.

If $x_i := a_i$, $y_j := b_j$ and $z_{ijk} := c_{ijk}$ is a solution of $\Pi^M$, then the set $\{(i, j, k) \mid c_{ijk} = 1\}$ defines a bijection between $A \times B$ and $M$, where $A := \{i \in M \setminus C \mid a_i = 1\}$, and $B := \{j \in M \setminus C \mid b_j = 1\}$. As $|A|, |B| < |M|$, such a solution exists only if $|M|$ is a composite number.

**Theorem 6.2.** For any prime $N$ there is no PC-refutation (resp. NS-refutation) of the system $\Pi^M$, $|M| = N$, of degree $t \leq \log_6(\log_6(N - 1))/3$ (resp. of degree $t \leq \log_6(N - 1)/3$).

**Proof.** Take $M$ to be of prime cardinality $N$, any $p^r$, and $r < p^\nu$. Take $N' := np^\nu + r$ for some suitable $n$ large enough such that $N'$ is composite. Then $\Pi^{N'}$ is solvable, i.e., non-refutable, while $N \equiv N' \mod p^\nu$. Hence Corollary 5.2 applies. \qed

**6.1. Acknowledgements.** This work was done while I was visiting the Mathematical Institute of the University of Oxford. I thank D. Macpherson for pointing out references [10, 11] and D. Evans for discussing this work with me. I am indebted to P. Pudlák, J. Sgall and A. Woods for a feedback during a lecture series where I presented this work.
