

## CONVERGENCE OF A CLASS OF DEFICIENT INTERPOLATORY SPLINES

S.S. RANA\*

**1. Introduction.** The most popular choice for reasonably efficient approximating functions still continues to be in favor of cubic splines (see de Boor [3, p. 49]). The interpolation problems of matching a cubic spline at one intermediate point and a deficient cubic spline at two intermediate points between the successive mesh points have been studied by Meir and Sharma [6]. For this case, further studies in the direction of the results proved in [6] have been made in [1, 4 and 5]. Instead of supplanting the additional degrees of freedom by prescribing values at two intermediate points for deficient cubic splines, our object is to study deficient cubic splines having two interpolatory conditions, one of which is the matching condition at intermediate points of the dividing intervals while the other is matching of derivatives at intermediate points. Interesting studies for sharp convergence properties for such spline interpolants when  $f \in C^3$  or  $f \in C^4$  have been made in the last section of the paper. It may be mentioned here that analysis to obtain the error bounds for interpolating deficient complex cubic splines is given by Chien-Kel Lu in [2].

**2. Existence and uniqueness.** Let a mesh on  $[0, 1]$  be given by

$$P : 0 = x_0 < x_1 < \cdots < x_n = 1$$

with  $p = x_i - x_{i-1}$  for  $i = 1, 2, \dots, n$ . For a positive integer  $m$ ,  $\pi_m$  denotes the set of algebraic polynomials of degree not greater than  $m$ . For a function  $s$  defined over  $P$ , we denote the restriction of  $s$  over  $[x_{i-1}, x_i]$  by  $s_i$ . The class of deficient cubic splines defined over  $P$  is given by

$$S(3, P) = \{s : s \in C^1[0, 1], s_i \in \pi_3 \text{ for } i = 1, 2, \dots, n\}.$$

Writing  $t_i = x_{i-1} + \alpha p$  and  $y_i = x_{i-1} + \beta p$  with  $0 < \alpha < 1$ ,  $0 \leq \beta \leq 1$ , and considering a function  $f$ , we propose

PROBLEM A. Suppose  $f'$  exists over  $P$ . Then under what restrictions on  $\alpha$  and  $\beta$  does there exist a unique spline interpolant  $s \in S(3, P)$  of  $f$  which satisfies the interpolatory conditions

$$(2.1) \quad s(y_i) = f(y_i)$$

$$(2.2) \quad s'(t_i) = f'(t_i)$$

for  $1 \leq i \leq n$  where  $f(y_i)$ 's and  $f'(t_i)$ 's are given functional values and derivatives respectively?

In order to investigate Problem A, we observe that, since  $s(x) \in S(3, P)$ ,  $s'(x)$  is piecewise quadratic. Therefore, for the interval  $[x_{i-1}, x_i]$ , we may write

$$(2.3) \quad p^2 s'(x) = p(x - x_{i-1})m_i + p(x_i - x)m_{i-1} + (x_i - x)(x - x_{i-1})c_i$$

where  $m_i = s'(x_i)$  and the  $c_i$ 's are appropriate constants which have to be determined. Integrating (2.3), we get

$$(2.4) \quad 6p^2 s(x) = 3p(x - x_{i-1})^2 m_i - 3p(x_i - x)^2 m_{i-1} + (x - x_{i-1})^2 (3(x_i - x) + (x - x_{i-1}))c_i + 6p^2 d_i.$$

We are now set to answer Problem A in

**THEOREM 1.** *Let  $f$  be 1-periodic. Then there exists a unique 1-periodic spline  $s(x)$  in the class  $S(3, P)$ , satisfying the interpolatory conditions (2.1) and (2.2) if (i)  $\alpha = 1/3$  and  $\beta \in [0, .84]$  or if (ii)  $\alpha = 2/3$  and  $\beta \in [.16, 1]$ , or if (iii)  $\alpha = 1/2$  and  $\beta \in (0, 1)$ .*

**PROOF.** Using the interpolatory conditions (2.1) and (2.2) in (2.4), we have,

$$(2.5) \quad 6f(y_i) = 3\beta^2 p m_i - 3(1 - \beta)^2 p m_{i-1} + (3 - 2\beta)\beta^2 p c_i + 6d_i$$

and

$$(2.6) \quad f'(t_i) = \alpha m_i + (1 - \alpha)m_{i-1} + \alpha(1 - \alpha)c_i.$$

Eliminating  $c_i, d_i$  between the equations (2.5) - (2.6) and using the requirement  $s \in C$ , we get

$$(2.7) \quad R_i m_{i-1} - (R_i + R_i^* + 1 - 6\alpha + 6\alpha^2)m_i + R_i^* m_{i+1} = F_i,$$

where  $R_i = (1 - \alpha)(1 - \beta)^2(3\alpha - 2\beta - 1)$ ,  $R_i^* = \alpha\beta^2(2\beta - 3\alpha)$  and

$$F_i = (6\alpha(1 - \alpha)(f(y_{i+1}) - f(y_i))/p) - \beta^2(3 - 2\beta)(f'(t_{i+1}) - f'(t_i)) - f'(t_i).$$

In order to prove Theorem 1, we consider all the cases of Theorem 1 separately. For case (i) in which  $\alpha = 1/3$  and  $\beta \in [0, .84]$ , the coefficient of  $m_{i+1}$  is nonpositive for  $0 \leq \beta \leq .5$  and nonnegative for  $.5 \leq \beta \leq .84$ . Further, the coefficients of  $m_{i-1}$  and  $m_i$  are always nonpositive and nonnegative respectively. Thus, the excess of the positive value of the coefficient of  $m_i$  over the sum of the positive values of the coefficients of  $m_{i-1}$  and  $m_{i+1}$  is  $1/3$  for  $0 \leq \beta \leq .5$  and  $(1 + 2\beta^2 - 4\beta^3)/3 = J_1(\beta)$ , say, for  $.5 \leq \beta \leq .84$ . For the case (ii) in which  $\alpha = 2/3$  and  $\beta \in [.16, 1]$ , we observe that the coefficient of  $m_{i-1}$  is nonnegative for  $.16 \leq \beta \leq .5$  and nonpositive for  $.5 \leq \beta \leq 1$ . However, the coefficients of  $m_{i+1}$  and  $m_i$  are always nonpositive and nonnegative respectively. Thus, the excess of the positive value of the coefficient of  $m_i$  over the sum of the positive values of the coefficients of  $m_{i-1}$  and  $m_{i+1}$  is  $(-1 + 8\beta - 10\beta^2 + 4\beta^3)/3 = J_2(\beta)$ , say, for  $.16 \leq \beta \leq .5$  and  $1/3$  for  $.5 \leq \beta \leq 1$ . Considering  $\alpha = 1/2$  and  $\beta \in (0, 1)$  for the last case of Theorem 1, we see that the coefficient of  $m_{i+1}$  is nonpositive for  $\beta \in (0, 3/4]$ , nonnegative for  $\beta \in [3/4, 1)$  and the coefficient of  $m_{i-1}$  in (2.7) is nonnegative for  $\beta \in (0, 1/4]$ , nonpositive for  $\beta \in [1/4, 1)$ . Further, the coefficient of  $m_i$  is nonnegative for  $\beta \in (0, 1)$ . Thus, the excess of the positive value of the coefficient of  $m_i$  over the sum of the positive values of the coefficients of  $m_{i-1}$  and  $m_{i+1}$  in (2.7) is  $\beta(6 - 9\beta + 4\beta^2)/2 = J_3(\beta)$ , say, for  $\beta \in (0, 1/4]$ ,  $1/2$  for  $\beta \in [1/4, 3/4]$  and  $(1 + 3\beta^2 - 4\beta^3)/2 = J_4(\beta)$ , say, for  $\beta \in [3/4, 1)$ . It may be seen easily that  $J_1(\beta)$ ,  $J_2(\beta)$ ,  $J_3(\beta)$  and  $J_4(\beta)$  are positive for corresponding values of  $\beta$ . Thus, the coefficient matrix  $A$  of the system of equations (2.7) is invertible and its row-max norm for  $\alpha = 1/3$  (or  $2/3$ ), that is,

$$(2.8) \quad \|A^{-1}\| \leq K_1$$

where  $K_1 = \max_{\beta} \{3, J_1^{-1}(\beta), J_2^{-1}(\beta)\}$ .  $\square$

Starting with the equation (2.7) and following closely the foregoing proof of Theorem 1, we can also prove a similar result for other choices of  $\alpha$  and  $\beta$ .

**THEOREM 2.** *Let  $f$  be 1-periodic. Then there exists a unique 1-periodic spline  $s(x)$  in the class  $S(3, P)$  satisfying the interpolatory conditions (2.1) and (2.2) if (i)  $\beta = 1/3$  and  $\alpha \in [2/9, .74]$  or if (ii)  $\beta = 2/3$  and  $\alpha \in [.22, 7/9]$  or if (iii)  $\beta = 1/2$  and  $\alpha \in [.23, 7/9]$ .*

**3. Error bounds.** In this section, we obtain the bounds of the function  $e = s - f$ , where  $s$  is the deficient cubic spline interpolant of  $f$  in  $S(3, P)$ . In what follows, we shall use the notation that, for the function  $f(x), f(x_i) = f_i$  and  $w(f, p)$  is the modulus of continuity of  $f$ . We shall prove

**THEOREM 3.** *Let  $f$  be a 1-periodic function in the class  $C^3[0, 1]$  and  $s(x)$  be its spline interpolant in  $S(3, P)$  of Theorem 1. Then, for  $r = 0, 1$ ,*

$$(3.1) \quad |(s - f)^{(r)}(x)| \leq K p^{3-r\omega}(f''', p)$$

where  $K$  is some positive constant.

**PROOF.** Writing  $m_i - f'_i = e'_i$ , we have from (2.7)

$$(3.2) \quad A(e'_i) = (F_i) - A(f'_i) = (D_i), \text{ say,}$$

where  $A$  is the coefficient matrix of the system of equations (2.7). In order to get the derivative of the error function, first we estimate  $(D_i)$ . Using the results that  $f(x) = f_j + (x - x_j)f'_j + (x - x_j)^2 f''_j/2 + (x - x_j)^3 f'''(\beta_j)/6$  and  $f'(x) = f'_j + (x - x_j)f''_j + (x - x_j)^2 f'''(\alpha_j)/2$ , where

$\alpha_j$  and  $\beta_j$  lie in the appropriate intervals, we see that

$$\begin{aligned}
 D_i = & (p^2/2)((1 - \alpha)^2 - (3 - 2\beta + 2\alpha\beta)\beta^2)|(f'''(\eta_i) - f'''(\alpha_i)) \\
 & + |2\alpha(1 - \alpha) - 3\alpha\beta(2 - 2\alpha + \alpha\beta)|(f'''(\beta_i) - f'''(\eta_i)) \\
 & + |2a(1 - a)\beta^3 - 3\alpha(2 - \alpha)\beta^2|(f'''(\alpha_i) - f'''(\beta_i)) \\
 & + 2\alpha\beta^3(f'''(\beta_{i+1}) - f'''(\theta_{i+1})) \\
 & + 2\alpha^2\beta^3(f'''(\alpha_{i+1}) - f'''(\beta_{i+1})) \\
 & + 3\alpha^2\beta^2(f'''(\theta_{i+1}) - f'''(\alpha_{i+1})),
 \end{aligned}$$

where  $z_i \in [x_{i-1}, x_i]$  for  $z = \alpha, \beta, \theta, \eta$ . Thus, in view of conditions of Theorem 1, we have, for  $\alpha = 1/3, 2/3$ ,

$$(3.3) \quad |D_i| \leq J(\alpha)p^2w(f''', p),$$

where  $J(1/3) = 1.75$  and  $J(2/3) = 5.12$ . Now, following the standard arguments based on the diagonal dominant property and using (2.8), (3.3) in (3.2), we get

$$(3.4) \quad \|(e_i)'\| \leq J(\alpha)K_1p^2w(f''', p)$$

where  $K_1$  is given by (2.8). Now combining (2.6) with (2.3), we replace  $s'(x)$  by  $e'(x)$  and  $m_i$  by  $e'_i$  in (2.3) and adjust suitably the additional terms by using the result of Taylor's Theorem to see that

$$(3.5) \quad 8\|e'(x)\| \leq 17\|(e_i)'\| + 4p^2w(f''', p).$$

Thus, using the estimate (3.4) in (3.5), we have

$$(3.6) \quad 8\|e'(x)\| \leq (4 + 17K_1J(\alpha))p^2w(f''', p).$$

This proves (3.1) for  $r = 1$ . The other inequality follows directly by an application of Rolle's Theorem.  $\square$

In order to study the convergence properties of deficient cubic spline interpolants for  $\alpha = 1/2$ , we consider  $f \in C^4[0, 1]$  and, using the results that  $f(x) = f_j + (x - x_j)f'_j + (x - x_j)^2f''_j/2 + (x - x_j)^3f'''_j/6$

$+(x - x_j)^4 f^{(4)}(\beta_j)/24$  and  $f'(x) = f'_j + (x - x_j)f''_j + (x - x_j)^2 f'''_j/2 + (x - x_j)^3 f^{(4)}(\alpha_j)/6$ , we have (from (3.2))

$$D_i = (p^3/48)(2|1 - 6\beta + 9\beta^2 - 4\beta^3|(f^{(4)}(\eta_i) - f^{(4)}(\beta_i)) + (f^{(4)}(\alpha_i) - f^{(4)}(\beta_i)) + 3\beta^4(f^{(4)}(\beta_{i+1}) - f^{(4)}(\beta_i)) + \beta^2(3 - 2\beta)((f^{(4)}(\theta_{i+1}) - f^{(4)}(\alpha_i)) + f^{(4)}(\theta_{i+1}) - f^{(4)}(\alpha_{i+1})) + 4\beta^3(f^{(4)}(\beta_i) - f^{(4)}(\theta_{i+1}))),$$

where  $z_i \in [x_{i-1}, x_i]$  for  $z = \alpha, \beta, \theta, \eta$ . Thus,

$$(3.7) \quad |D_i| \leq (5/24)p^3 w(f^{(4)}, p).$$

Writing  $K_2$  for  $\max_{\beta} \{J_3^{-1}(\beta), 2, J_4^{-1}(\beta)\}$ , where  $J_3(\beta)$  and  $J_4(\beta)$  have already been defined in §2, and, again using the standard arguments, we have

$$(3.8) \quad \|(e_i)'\| \leq (5/24)K_2 p^3 w(f^{(4)}, p).$$

Hence, by a reasoning used already in the proof of Theorem 3, we have

$$(3.9) \quad \|e'\| \leq K_3 p^3 w(f^{(4)}, p),$$

where  $K_3$  is some positive constant. We have thus proven

**THEOREM 4.** *Let  $f$  be a 1-periodic function in the class  $C^4[0, 1]$  and  $s(x)$  be its spline interpolant in  $S(3, P)$ . Then, for  $j = 0, 1$  and  $\alpha = 1/2$ ,*

$$(3.10) \quad \|(s - f)^{(j)}(x)\| \leq p^{4-j} K_3 w(f^{(4)}, p),$$

where  $K_3$  is a positive constant.

(3.9) proves Theorem 4 for  $j = 1$ . The other inequality for  $j = 0$  follows directly by integration.  $\square$
