# GENERIC SUBIDEALS OF GRAPH IDEALS AND FREE RESOLUTIONS 

LEAH GOLD

#### Abstract

For a graph of an $n$-cycle $\Delta$ with Alexander dual $\Delta^{*}$, we study the free resolution of a subideal $G(n)$ of the Stanley-Reisner ideal $I_{\Delta^{*}}$. We prove that if $G(n)$ is generated by 3 generic elements of $I_{\Delta^{*}}$, then the second syzygy module of $G(n)$ is isomorphic to the second syzygy module of $\left(x_{1}, x_{2}, \ldots, x_{n}\right)$. A result of Bruns shows that there is always a 3 -generated ideal with this property. We show that it can be chosen to have a particularly nice form.

1. Introduction and background. Let $\Delta$ be a cycle and $\Delta^{*}$ its Alexander dual. The Stanley-Reisner ideals of such graphs and their free resolutions have been studied by many people, such as in $[\mathbf{1}, \mathbf{2}, \mathbf{8}$, $\mathbf{9}, \mathbf{1 5}, 16]$. In this paper we study the free resolution of a subideal $G(n)$ of $I_{\Delta^{*}}$ consisting of three generic elements of $I_{\Delta^{*}}$. The study of these ideals led to the following observation, which is our main theorem.

Theorem 1. Let $G(n)$ be as above and let $\operatorname{Syz}_{2}(G(n))$ be the module of second syzygies. Then the resolution of $\mathrm{Syz}_{2}(G(n))$ is the same as that of $\operatorname{Syz}_{2}\left(\left(x_{1}, x_{2}, \ldots, x_{n}\right)\right)$.

That is to say, the tails of the resolutions, i.e., the modules and maps in the later part of the complexes, of the ideals $G(n)$ and $\left(x_{1}, x_{2}, \ldots, x_{n}\right)$ are identical. For example, in five variables the three generators of $G(5)$ are $\alpha=r_{1} c d e+r_{2} a d e+r_{3} a b e+r_{4} b c d+r_{5} a b c$, $\beta=s_{1} c d e+s_{2} a d e+s_{3} a b e+s_{4} b c d+s_{5} a b c$, and $\gamma=t_{1} c d e+t_{2} a d e+$ $t_{3} a b e+t_{4} b c d+t_{5} a b c$. The minimal free resolution of $G(5)$ looks like

$$
0 \longrightarrow R \xrightarrow{d_{5}} R^{5} \xrightarrow{d_{4}} R^{10} \xrightarrow{\varphi_{3}} R^{8} \xrightarrow{\varphi_{2}} R^{3} \xrightarrow{\varphi_{1}} R
$$

where the maps $d_{4}$ and $d_{5}$ are exactly the same as the ones for the resolution of $(a, b, c, d, e)$.

[^0]Received by the editors on July 12, 2004, and in revised form on Sept. 13, 2004.

A result of Bruns [3] shows that for any ideal $I$ and any integer $m$, there exists a 3-generated ideal $I^{\prime}$ such that the resolutions of $\mathrm{Syz}_{m} I$ and $\operatorname{Syz}_{m}\left(I^{\prime}\right)$ are identical. A consequence of our study of these graph ideals is that we have found a particularly simple 3 -generated ideal related to the Koszul complex on the ideal of variables.
1.1 Criterion for exactness. If $\mathcal{F}$ is a complex of finitely generated free modules over a Noetherian ring, the necessary and sufficient conditions for exactness are given by the following result due to Buchsbaum and Eisenbud [6].
Let $\varphi$ be a matrix of $\operatorname{rank} r$. Define $I(\varphi)=I_{r}(\varphi)$ to be the ideal generated by the $r \times r$ minors of $\varphi$.

Theorem 2 (Buchsbaum, Eisenbud). Let $R$ be a Noetherian ring. A complex

$$
\mathcal{F}: 0 \longrightarrow F_{n} \xrightarrow{\varphi_{n}} F_{n-1} \xrightarrow{\varphi_{n-1}} \cdots \xrightarrow{\varphi_{2}} F_{1} \xrightarrow{\varphi_{1}} F_{0}
$$

of finitely generated free $R$-modules is exact if and only if for all $k=1,2, \ldots, n$,
(1) $\operatorname{rank}\left(\varphi_{k}\right)+\operatorname{rank}\left(\varphi_{k+1}\right)=\operatorname{rank}\left(F_{k}\right)$, and
(2) $\operatorname{depth}\left(I\left(\varphi_{k}\right)\right) \geq k$.

Note, for any complex $\operatorname{rank}\left(\varphi_{k}\right)+\operatorname{rank}\left(\varphi_{k+1}\right) \leq \operatorname{rank}\left(F_{k}\right)$. Hence Condition (1) asserts equality.
Recall that depth $(I)$ is the length of a maximal $R$-sequence contained in $I$. In general, the depth of an ideal is less than or equal to its codimension. In the case of a polynomial ring, the depth of an ideal is equal to its codimension, and the codimension of an ideal is equal to the codimension of its radical. Hence, we may restate Condition (2) as $\operatorname{codim}\left(\operatorname{rad}\left(I\left(\varphi_{k}\right)\right)\right) \geq k$.
1.2 Buchsbaum-Eisenbud structure theorem. In 1974 Buchsbaum and Eisenbud published a paper containing some structure theorems for finite free resolutions [7]. The structure theorems were further explained and slightly generalized in papers by Eagon and Northcott [10], and Bruns [4]. The assumptions they made may be relaxed
in the case when $R$ is an integral domain. Since we are working over an integral domain, we state the structure theorem for this case.

Definition 3. Let $A=\left(a_{i, j}\right)$ be a $p \times q$ matrix, and let $\nu$ be a non-negative integer. We say that $A$ factorizes completely if there exist elements $u_{1}, \ldots, u_{p}$ and $v_{1}, \ldots, v_{q}$ of $R$ such that $a_{i, j}=u_{i} v_{j}$ for all $i$ and $j$. When $A$ is a row matrix, that is, when $p=1$, we say that the complete factorization $u_{1}=1$ and $v_{j}=a_{1, j}$ is the canonical complete factorization.

The entries of $\wedge^{\nu} A$ are the $\nu \times \nu$ minors of the matrix $A$. If $J=\left\{j_{1}, \ldots, j_{\nu}\right\}$ with $1 \leq j_{1}<j_{2}<\cdots<j_{\nu} \leq p$ and $K=\left\{k_{1}, \ldots, k_{\nu}\right\}$ with $1 \leq k_{1}<k_{2}<\cdots<k_{\nu} \leq q$, then

$$
\left(\bigwedge^{\nu} A\right)_{J, K}=\operatorname{det}\left(\begin{array}{cccc}
a_{j_{1}, k_{1}} & a_{j_{1}, k_{2}} & \cdots & a_{j_{1}, k_{\nu}} \\
a_{j_{2}, k_{1}} & a_{j_{2}, k_{2}} & \cdots & a_{j_{2}, k_{\nu}} \\
\vdots & \vdots & \ddots & \vdots \\
a_{j_{\nu}, k_{1}} & a_{j_{\nu}, k_{2}} & \cdots & a_{j_{\nu}, k_{\nu}}
\end{array}\right)
$$

Now let $B$ be a $q \times t$ matrix. Let $\mu$ and $\nu$ be non-negative integers such that $\mu+\nu=q$. Assume that $\wedge^{\mu} A$ and $\wedge^{\nu} B$ factorize completely. Thus, $\left(\wedge^{\mu} A\right)_{J, K}=u_{J} v_{K}$ and $\left(\wedge^{\nu} B\right)_{M, N}=w_{M} z_{N}$.

Definition 4. The two factorizations above are said to be complementary if, for every $M, w_{M}=\operatorname{sgn}\left(M, M^{\prime}\right) v_{M^{\prime}}$ where $M^{\prime}$ denotes the complement of $M$ in $\{1,2, \ldots, q\}$.

Proposition 5 (Eagon, Northcott). Let $\mu=\operatorname{rank}(A)$ and $\nu=$ $\operatorname{rank}(B)$. Suppose that $A B=0$ with $\mu+\nu=q$. Assume that there is given a complete factorization of $\wedge^{\mu} A$ and that $\operatorname{codim}\left(I_{\mu}(A)\right) \geq$ 2. Then there is a unique complete factorization of $\wedge^{\nu} B$ that is complementary to the given factorization of $\wedge^{\mu} A$.

Using this proposition, Eagon and Northcott reproved the first structure theorem of Buchsbaum and Eisenbud.

Corollary 6 (Buchsbaum, Eisenbud). Let

$$
\mathcal{C}: 0 \longrightarrow F_{n} \xrightarrow{\varphi_{n}} F_{n-1} \xrightarrow{\varphi_{n-1}} \cdots \xrightarrow{\varphi_{2}} F_{1} \xrightarrow{\varphi_{1}} R
$$

be a complex of finitely generated free $R$-modules. Choose a basis for each $F_{i}$, and let $A_{i}$ be the matrix with respect to these bases for $1 \leq i \leq n$. Suppose $\operatorname{codim}\left(I\left(\varphi_{i}\right)\right) \geq 2$ for all $i \geq 2$. Then, for $1 \leq i \leq n$, there exist ideals $B_{i}$ such that $I\left(\varphi_{n}\right)=B_{n}$ and $I\left(\varphi_{i}\right)=B_{i+1} B_{i}$ for $1 \leq i \leq n-1$.
1.3 Bruns's construction. Suppose we restrict our discussion to ideals with a given number of generators. An ideal with a single generator has no syzygies and a trivial resolution. An ideal with two generators has a single first syzygy and a simple resolution. When we consider an ideal with three generators, however, the resolutions are more complicated. In 1976, Bruns published a result in [3] which proved, in more generality, a conjecture of Buchsbaum and Eisenbud from Section 11 of their paper [7]. This result showed that every finite free resolution has the same tail as the finite free resolution of a 3 -generated ideal. The following theorem is a special case of a Bruns's result.

Theorem 7 (Bruns). Let $R$ be a polynomial ring, and let $I$ be an ideal of $R$. Suppose that a projective resolution of $R / I$ has the form

$$
0 \longrightarrow F_{n} \xrightarrow{f_{n}} F_{n-1} \longrightarrow \cdots \longrightarrow F_{3} \xrightarrow{f_{3}} F_{2} \xrightarrow{f_{2}} F_{1} \xrightarrow{f_{1}} R .
$$

Let $r:=\operatorname{rank}\left(f_{3}\right)$. Then there exist homomorphisms c: $F_{2} \rightarrow R^{r+2}$, $f_{2}^{\prime}: R^{r+2} \rightarrow R^{3}, f_{1}^{\prime}: R^{3} \rightarrow R$ with $f_{3}^{\prime}=c \circ f_{3}$, such that the sequence

$$
0 \longrightarrow F_{n} \xrightarrow{f_{n}} F_{n-1} \longrightarrow \cdots \longrightarrow F_{4} \xrightarrow{f_{4}} F_{3} \xrightarrow{f_{3}^{\prime}} R^{r+2} \xrightarrow{f_{2}^{\prime}} R^{3} \xrightarrow{f_{1}^{\prime}} R
$$

is exact.

Note that $c$ is a projection. Also notice that there are many homomorphisms $c, f_{1}$, and $f_{2}$ that satisfy the theorem.

Definition 8. Let $I$ and $J$ be ideals, and let the minimal free resolutions of $R / I$ and $R / J$, respectively, be of the form

$$
\mathcal{F}: 0 \longrightarrow F_{n} \xrightarrow{f_{n}} F_{n-1} \xrightarrow{f_{n-1}} \cdots \xrightarrow{f_{3}} F_{2} \xrightarrow{f_{2}} F_{1} \xrightarrow{f_{1}} R
$$

and

$$
\mathcal{G}: 0 \longrightarrow G_{n} \xrightarrow{g_{n}} G_{n-1} \xrightarrow{g_{n-1}} \cdots \xrightarrow{g_{3}} G_{2} \xrightarrow{g_{2}} G_{1} \xrightarrow{g_{1}} R .
$$

We say that $I$ and $J$ are tail resolution equivalent if the modules $F_{i}=$ $G_{i}$ for $3 \leq i \leq n$, and the maps $f_{i}=g_{i}$ for $4 \leq i \leq n$.

This definition is an equivalence relation on ideals. With this definition, we can restate the result of Theorem 7: For any ideal $I$, there is a 3-generated ideal $J$ that is tail resolution equivalent to $I$.

In the remainder of this paper, we will develop our main result, namely, a method of constructing simple ideals that are tail resolution equivalent to $\left(x_{1}, x_{2}, \ldots, x_{n}\right)$.
2. A special family of 3-generated ideals. We will now describe a family of 3 -generated ideals. Fix an integer $n \geq 4$. Let $K$ be the complete graph on $n$ vertices. Let $R=k\left[x_{1}, x_{2}, \ldots, x_{n}\right]$ where $k=k^{\prime}\left(r_{1}, r_{2}, \ldots, r_{n}, s_{1}, s_{2}, \ldots, s_{n}, t_{1}, t_{2}, \ldots, t_{n}\right)$ and $k^{\prime}$ is a field. Label the vertices of $K$ by the $x_{i}$ 's. Let the graph $L$ be the complement of the cycle $\Delta=\left\{\left(x_{1}, x_{2}\right),\left(x_{2}, x_{3}\right), \ldots,\left(x_{n}, x_{1}\right)\right\}$ in $K$. Let the ideal $I$ be

$$
\bigcap_{\left\{x_{i}, x_{j}\right\} \in L}\left(x_{i}, x_{j}\right)
$$

This ideal $I$ is $I_{\Delta^{*}}$, the Alexander dual of the Stanley-Reisner ideal of $\Delta$. For convenience, let $\mathbf{m}_{i_{1}, i_{2}, \ldots, i_{k}}=\prod_{p \neq i_{1}, i_{2}, \ldots, i_{k}} x_{p}$. Wherever subscripts appear, consider them as being modulo $n$, so, for example, $\mathbf{m}_{n, n+1}=x_{2} \cdots x_{n-1}$. Then the $n$ generators of $I$ are $\mathbf{m}_{i, i+1}$, for $i=1, \ldots, n$.

Now we want to take a generic linear combination of these generators. So let $M$ be the $3 \times n$ matrix

$$
\left(\begin{array}{llll}
r_{1} & r_{2} & \cdots & r_{n} \\
s_{1} & s_{2} & \cdots & s_{n} \\
t_{1} & t_{2} & \cdots & t_{n}
\end{array}\right) .
$$

Define the ideal $G(n)$ to be the 3-generated ideal whose generators are the entries of $\left(\mathbf{m}_{1,2} \mathbf{m}_{2,3} \cdots \mathbf{m}_{n, 1}\right) M^{t}$.

Example 9. Consider the graph on four vertices, labeled $a, b, c$ and $d$, with edge set $K-\{\{a, b\},\{b, c\},\{c, d\},\{d, a\}\}=\{\{a, c\},\{b, d\}\}$.

The monomial ideal $I$ is $(a, c) \cap(b, d)=(a b, b c, a d, c d)$. We find the 3-generated ideal $G(4)$ by taking generic combinations of $a b, b c, a d$ and $c d$. So, $G(4)=\left(r_{1} c d+r_{2} a d+r_{3} b c+r_{4} a b, s_{1} c d+s_{2} a d+s_{3} b c+\right.$ $\left.s_{4} a b, t_{1} c d+t_{2} a d+t_{3} b c+t_{4} a b\right)$.

Due to the construction, it is clear that $G(n) \subset\left(x_{i}, x_{j}\right)$ for all $i$ and $j$ that are nonadjacent integers modulo $n$. Each ideal ( $x_{i}, x_{j}$ ) where $i$ and $j$ are not adjacent modulo $n$, therefore, is a codimension two component of $G(n)$. The following proposition shows that there are no other codimension two components.

Lemma 10. If $P$ is a codimension two associated prime of the ideal $G(n)$ and if $x_{i} \in P$, then $P=\left(x_{i}, x_{j}\right)$ for some $j$ that is not adjacent modulo $n$ to $i$.

Proof. Let $G(n)=(\alpha, \beta, \gamma)$, so $\alpha, \beta, \gamma$ are contained in $P$. Separate the terms of the generators of $G(n)$ into those that involve $x_{i}$ and those that do not.

$$
\begin{aligned}
\alpha & =f x_{i}+r_{i-1} \mathbf{m}_{i-1, i}+r_{i} \mathbf{m}_{i, i+1} \\
& =f x_{i}+\left(r_{i-1} x_{i+1}+r_{i} x_{i-1}\right) \mathbf{m}_{i-1, i, i+1} \\
\beta & =g x_{i}+s_{i-1} \mathbf{m}_{i-1, i}+s_{i} \mathbf{m}_{i, i+1} \\
& =g x_{i}+\left(s_{i-1} x_{i+1}+s_{i} x_{i-1}\right) \mathbf{m}_{i-1, i, i+1} \\
\gamma & =h x_{i}+t_{i-1} \mathbf{m}_{i-1, i}+t_{i} \mathbf{m}_{i, i+1} \\
& =h x_{i}+\left(t_{i-1} x_{i+1}+t_{i} x_{i-1}\right) \mathbf{m}_{i-1, i, i+1} .
\end{aligned}
$$

Since $x_{i} \in P$, we also have that $\alpha-f x_{i}, \beta-g x_{i}$, and $\gamma-h x_{i}$ are in $P$. Therefore, either the terms $r_{i-1} x_{i+1}+r_{i} x_{i-1}, s_{i-1} x_{i+1}+s_{i} x_{i-1}$, and $t_{i-1} x_{i+1}+t_{i} x_{i-1}$ are in $P$, or $x_{j}$ is in $P$ for some $j \neq i-1, i, i+1$. In the former case, $x_{i-1}$ and $x_{i+1}$ are in $P$ along with $x_{i}$, and this contradicts $\operatorname{codim}(P)=2$. In the latter case, we get the desired result.

Proposition 11. The codimension two associated primes of the ideal $G(n)$ are exactly the ideals $\left(x_{i}, x_{j}\right)$ where $1 \leq i<j \leq n$ and $i, j$ are not adjacent integers modulo $n$.

Proof. Let $G(n)=(\alpha, \beta, \gamma)$. The ideals $\left(x_{i}, x_{j}\right)$ where $i$ and $j$ are not adjacent modulo $n$ are certainly codimension 2 components of $G(n)$.
Now, suppose $P$ is some other prime ideal of codimension two containing $G(n)$. We will show that no such $P$ exists.

If $P$ contains a variable, then by Lemma 10 it is of the form $\left(x_{i}, x_{j}\right)$ where $i$ and $j$ are not adjacent modulo $n$. Hence, we may assume that $P$ does not contain any variables.

Write the generators of $G(n)$ by splitting them into those terms that involve $x_{1}$ and those that do not:

$$
\begin{aligned}
\alpha & =f x_{1}+r_{1} \mathbf{m}_{1,2}+r_{n} \mathbf{m}_{1, n}=f x_{1}+\mathbf{m}_{1,2, n} l_{1} \\
\beta & =g x_{1}+s_{1} \mathbf{m}_{1,2}+s_{n} \mathbf{m}_{1, n}=g x_{1}+\mathbf{m}_{1,2, n} l_{2} \\
\gamma & =h x_{1}+t_{1} \mathbf{m}_{1,2}+t_{n} \mathbf{m}_{1, n}=h x_{1}+\mathbf{m}_{1,2, n} l_{3}
\end{aligned}
$$

where

$$
\begin{gathered}
f=r_{2} \mathbf{m}_{1,2,3}+r_{3} \mathbf{m}_{1,3,4}+\cdots+r_{n-1} \mathbf{m}_{1, n-1, n} \\
g=s_{2} \mathbf{m}_{1,2,3}+s_{3} \mathbf{m}_{1,3,4}+\cdots+s_{n-1} \mathbf{m}_{1, n-1, n} \\
h=t_{2} \mathbf{m}_{1,2,3}+t_{3} \mathbf{m}_{1,3,4}+\cdots+t_{n-1} \mathbf{m}_{1, n-1, n} \\
l_{1}=\left(r_{1} x_{n}+r_{n} x_{2}\right), \quad l_{2}=\left(s_{1} x_{n}+s_{n} x_{2}\right), \quad l_{3}=\left(t_{1} x_{n}+t_{n} x_{2}\right) .
\end{gathered}
$$

There are two cases: either $P$ contains $f, g$, and $h$, or it does not contain at least one of them.

Case 1. $f, g, h \in P$.
Since $\alpha, \beta$, and $\gamma$ are in $P$, we also know that $P$ contains $\mathbf{m}_{1,2, n}\left(r_{1} x_{n}+\right.$ $\left.r_{n} x_{2}\right), \mathbf{m}_{1,2, n}\left(s_{1} x_{n}+s_{n} x_{2}\right)$, and $\mathbf{m}_{1,2, n}\left(t_{1} x_{n}+t_{n} x_{2}\right)$. Since $P$ does not contain any variables, $\left(r_{1} x_{n}+r_{n} x_{2}\right),\left(s_{1} x_{n}+s_{n} x_{2}\right)$, and $\left(t_{1} x_{n}+t_{n} x_{2}\right)$ are in $P$. Containing these elements also forces $x_{2}$ and $x_{n}$ to be in $P$, and this contradicts our assumption that there are no variables in $P$.

Case 2. One of $f, g, h$ is not in $P$.

Without loss of generality, suppose $f \notin P$.
Let $\widehat{P}=P \cap k\left[x_{2}, \ldots, x_{n}\right]$. Since $\alpha, \beta, \gamma \in P$, we have the elements

$$
\begin{aligned}
f \beta-g \alpha & =\mathbf{m}_{1,2, n}\left(f l_{2}-g l_{1}\right), \\
f \gamma-h \alpha & =\mathbf{m}_{1,2, n}\left(f l_{3}-h l_{1}\right), \quad \text { and } \\
g \gamma-h \beta & =\mathbf{m}_{1,2, n}\left(g l_{3}-h l_{2}\right)
\end{aligned}
$$

are in $\widehat{P}$. The prime ideal $\widehat{P}$ does not contain any variables, so $f l_{2}-g l_{1}$, $f l_{3}-h l_{1}$, and $g l_{3}-h l_{2}$ are in $\widehat{P}$.
Since $P$ is codimension two, $V(P)$ is dimension $n-2$. The projection, $p$, from $n$ variables to $n-1$ variables given by dropping $x_{1}$ gives a birational map between $V(P)$ and its image $p(V(P))$. So $p(V(P))$ is also dimension $n-2$, hence $\widehat{P}$ is codimension $(n-1)-(n-2)=1$.
Since $\widehat{P}$ is codimension one, these elements must have a common factor. We claim, however, that they are irreducible. So, we have a contradiction and such a $P$ cannot exist.
It is now sufficient to show that $f l_{2}-g l_{1}$ is irreducible.

$$
\begin{aligned}
g l_{1}-f l_{2}= & {\left[s_{2} \mathbf{m}_{1,2,3}+s_{3} \mathbf{m}_{1,3,4}+\cdots+s_{n-1} \mathbf{m}_{1, n-1, n}\right]\left(r_{1} x_{n}+r_{n} x_{2}\right) } \\
& -\left[r_{2} \mathbf{m}_{1,2,3}+r_{3} \mathbf{m}_{1,3,4}+\cdots+r_{n-1} \mathbf{m}_{1, n-1, n}\right]\left(s_{1} x_{n}+s_{n} x_{2}\right) \\
= & {\left[\left(r_{1} s_{2}-r_{2} s_{1}\right) x_{4} \cdots x_{n}^{2}+\left(r_{1} s_{3}-r_{3} s_{1}\right) x_{2} x_{5} \cdots x_{n}^{2}+\cdots\right.} \\
& +\left(r_{1} s_{n-2}-r_{n-2} s_{1}\right) x_{2} \cdots x_{n-3} x_{n}^{2}+\left(r_{1} s_{n-1}-r_{n-1} s_{1}\right) x_{2} \\
& \left.\cdots x_{n-2} x_{n}\right] \\
& +\left[\left(r_{n} s_{2}-r_{2} s_{n}\right) x_{2} x_{4} \cdots x_{n}+\left(r_{n} s_{3}-r_{3} s n\right) x_{2}^{2} x 5 \cdots x_{n}+\cdots\right. \\
& +\left(r_{n} s_{n-2}-r_{n-2} s_{n}\right) x_{2}^{2} x_{3} \cdots x_{n-3} x_{n} \\
& \left.+\left(r_{n} s_{n-1}-r_{n-1} s_{n}\right) x_{2}^{2} x_{3} \cdots x_{n-2}\right] .
\end{aligned}
$$

Letting $z_{i}=\left(r_{1} s_{i}-r_{i} s_{1}\right) x_{n}+\left(r_{n} s_{i}-r_{i} s_{n}\right) x_{2}$, we can rewrite the above expression.

$$
\begin{aligned}
& z_{2} \mathbf{m}_{1,2,3}+z_{3} \mathbf{m}_{1,3,4}+ z_{4} \\
&=\mathbf{m}_{1,4,5}+\cdots+z_{n-1} \mathbf{m}_{1, n-1, n} \\
&=\left(z_{2} x_{4}+z_{3} x_{2}\right) x_{5} \cdots x_{n}+x_{2} x_{3}\left(z_{4} x_{6} \cdots x_{n}\right. \\
&\left.+z_{5} x_{4} x_{7} \cdots x_{n}+\cdots+z_{n-1} x_{4} \cdots x_{n-2}\right) \\
&= \delta+x_{3} \varepsilon
\end{aligned}
$$

In order for this expression to factor, $\delta$ and $\varepsilon$ must have a common factor. None of the variables divide all terms of both $\delta$ and $\varepsilon$, so the factor cannot be divisible by a variable. So, the only possible common factor is $z_{2} x_{4}+z_{3} x_{2}$. In order for $z_{2} x_{4}+z_{3} x_{2}$ to divide the sum of the latter terms, any specialization of the variables that make this expression zero must also make the sum of the latter terms zero. Consider the specialization where $x_{4}=0, x_{2}=r_{3} s_{1}-r_{1} s_{3}$, $x_{n}=r_{n} s_{3}-r_{3} s_{n}$ and all the other variables are nonzero. Then $z_{2} x_{4}+z_{3} x_{2}$ becomes 0 , but the remaining term of the sum $z_{4} x_{6} \cdots x_{n-1}$ is nonzero. Hence this expression is irreducible.
3. The tail resolution equivalence. With the help of a computer and Macaulay 2 [13], it is easy to construct examples of the ideals discussed in Section 2. When we do so for rings with between 4 and 12 variables and look at their resolutions, the results are rather striking.

Example 12. In four variables, using the construction from the previous section, we find that the ideal $I$ is generated by $a b, b c, a d$, and $c d$ and the three-generated ideal $G(4)$ is generated by

$$
\begin{aligned}
\alpha & =r_{1} c d+r_{2} a d+r_{3} b c+r_{4} a b, \\
\beta & =s_{1} c d+s_{2} a d+s_{3} b c+s_{4} a b, \quad \text { and } \\
\gamma & =t_{1} c d+t_{2} a d+t_{3} b c+t_{4} a b .
\end{aligned}
$$

The resolution of $R / G(4)$ has the following form.

$$
0 \longrightarrow R \xrightarrow{d_{4}} R^{4} \xrightarrow{\varphi_{3}} R^{5} \xrightarrow{\varphi_{2}} R^{3} \xrightarrow{\varphi_{1}} R .
$$

The maps in the resolution may be written as follows.

$$
\begin{aligned}
\varphi_{1} & =\left(\begin{array}{ccccc}
\alpha & \beta & \gamma
\end{array}\right) \\
\varphi_{2} & =\left(\begin{array}{ccccc}
0 & \gamma & \beta & * & * \\
\gamma & 0 & -\alpha & * & * \\
-\beta & -\alpha & 0 & * & *
\end{array}\right)
\end{aligned}
$$

where the fourth column is

$$
\begin{array}{cccccccc}
-\left(s_{2} t_{4}-s_{4} t_{2}\right) & a^{2} & -\left(s_{1} t_{4}-s_{4} t_{1}\right) & a c & -\left(s_{2} t_{3}-s_{3} t_{2}\right) & a c & -\left(s_{1} t_{3}-s_{3} t_{1}\right) & c^{2} \\
\left(r_{2} t_{4}-r_{4} t_{2}\right) & a^{2} & +\left(r_{1} t_{4}-r_{4} t_{1}\right) & a c & +\left(r_{2} t_{3}-r_{3} t_{2}\right) & a c & +\left(r_{1} t_{3}-r_{3} t_{1}\right) & c^{2} \\
-\left(r_{2} s_{4}-r_{4} s_{2}\right) & a^{2} & -\left(r_{1} s_{4}-r_{4} s_{1}\right) & a c & -\left(r_{2} s_{3}-r_{3} s_{2}\right) & a c & -\left(r_{1} s_{3}-r_{3} s_{1}\right) & c^{2}
\end{array}
$$

and the fifth column is

$$
\begin{aligned}
& -\left(s_{4} t_{3}-s_{3} t_{4}\right) \quad b^{2} \quad+\left(s_{1} t_{4}-s_{4} t_{1}\right) \quad b d \quad-\left(s_{2} t_{3}-s_{3} t_{2}\right) \quad b d \quad+\left(s_{1} t_{2}-s_{2} t_{1}\right) \quad d^{2} \\
& \begin{array}{llllllll}
\left(r_{4} t_{3}-r_{3} t_{4}\right) & b^{2} & -\left(r_{1} t_{4}-r_{4} t_{1}\right) & b d & +\left(r_{2} t_{3}-r_{3} t_{2}\right) & b d & -\left(r_{1} t_{2}-r_{2} t_{1}\right) & d^{2} \\
& r^{2}
\end{array} \\
& -\left(r_{4} s_{3}-r_{3} s_{4}\right) \quad b^{2}+\left(r_{1} s_{4}-r_{4} s_{1}\right) \quad b d \quad-\left(r_{2} s_{3}-r_{3} s_{2}\right) \quad b d \quad+\left(r_{1} s_{2}-r_{2} s_{1}\right) \quad d^{2} \\
& \varphi_{3}=\left(\begin{array}{cccc}
r_{2} a+r_{1} c & r_{3} b+r_{1} d & r_{4} a+r_{3} c & r_{4} b+r_{2} d \\
-s_{2} a-s_{1} c & -s_{3} b-s_{1} d & -s_{4} a-s_{3} c & -s_{4} b-s_{2} d \\
t_{2} a+t_{1} c & t_{3} b+t_{1} d & t_{4} a+t_{3} c & t_{4} b+t_{2} d \\
-b & 0 & d & 0 \\
0 & a & 0 & -c
\end{array}\right) \\
& d_{4}=\left(\begin{array}{c}
-d \\
c \\
-b \\
a
\end{array}\right)
\end{aligned}
$$

Notice that if we specialize to $r_{1}=s_{4}=t_{2}=t_{3}=1$ and set all other coefficients to zero, then $G(4)=(a b, c d, a d+b c)$. This is the ideal whose resolution is Buchsbaum and Eisenbud's structure theorems paper [7, Example 2, Section 11].

Example 13. In five variables, $G(5)$ has the following generators.

$$
\begin{aligned}
\alpha & =r_{1} c d e+r_{2} a d e+r_{3} a b e+r_{4} b c d+r_{5} a b c \\
\beta & =s_{1} c d e+s_{2} a d e+s_{3} a b e+s_{4} b c d+s_{5} a b c \\
\gamma & =t_{1} c d e+t_{2} a d e+t_{3} a b e+t_{4} b c d+t_{5} a b c .
\end{aligned}
$$

The resolution of $R /(\alpha, \beta, \gamma)$ is as follows.

$$
0 \longrightarrow R \xrightarrow{d_{5}} R^{5} \xrightarrow{d_{4}} R^{10} \xrightarrow{\varphi_{3}} R^{8} \xrightarrow{\varphi_{2}} R^{3} \xrightarrow{\varphi_{1}} \longrightarrow R
$$

where the $d_{i}$ 's are the Koszul maps on the variables $a, b, c, d, e$ and the other maps are defined as follows.

$$
\begin{aligned}
\varphi_{1} & =\left(\begin{array}{lll}
\alpha & \beta & \gamma
\end{array}\right) \\
\varphi_{2} & =\left(\begin{array}{cccccccc}
0 & \gamma & \beta & * & * & * & * & * \\
\gamma & 0 & -\alpha & * & * & * & * & * \\
-\beta & -\alpha & 0 & * & * & * & * & *
\end{array}\right)
\end{aligned}
$$

In order to condense the matrices so that they fit on the page, let $x y l m=x_{l} y_{m}-x_{m} y_{l}$. The missing entries from the above matrix can be written as the product of a $3 \times 10$ matrix with a $10 \times 5$ matrix.

$$
\left.\begin{array}{cccccccccc}
s t 12 & s t 13 & s t 15 & s t 14 & s t 23 & s t 25 & s t 24 & s t 35 & s t 34 & s t 54 \\
-r t 12 & -r t 13 & -r t 15 & -r t 14 & -r t 23 & -r t 25 & -r t 24 & -r t 35 & -r t 34 & -r t 54 \\
r s 12 & r s 13 & r s 15 & r s 14 & r s 23 & r s 25 & r s 24 & r s 35 & r s 34 & r s 54
\end{array}\right)
$$

The matrix $\varphi_{3}$ is formed of two parts $\left(\frac{A}{B}\right)$ where

$$
\begin{aligned}
& A=\left(\begin{array}{ccccc}
r_{1} & r_{2} & r_{3} & r_{4} & r_{5} \\
-s_{1} & -s_{2} & -s_{3} & -s_{4} & -s_{5} \\
t_{1} & t_{2} & t_{3} & t_{4} & t_{5}
\end{array}\right) \\
& \times\left(\begin{array}{llllllllll}
c & d & e & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
a & 0 & 0 & 0 & 0 & 0 & d & e & 0 & 0 \\
0 & 0 & 0 & a & 0 & 0 & b & 0 & 0 & e \\
0 & 0 & b & 0 & c & d & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & a & 0 & 0 & b & c
\end{array}\right)
\end{aligned}
$$

and

$$
B=\left(\begin{array}{cccccccccc}
-b & 0 & 0 & d & e & 0 & 0 & 0 & 0 & 0 \\
0 & -b & 0 & -c & 0 & e & 0 & 0 & 0 & 0 \\
0 & a & 0 & 0 & 0 & 0 & -c & 0 & e & 0 \\
0 & 0 & a & 0 & 0 & 0 & 0 & -c & -d & 0 \\
0 & 0 & 0 & 0 & a & 0 & 0 & b & 0 & -d
\end{array}\right)
$$

Example 14. In six variables, $G(6)$ has the following generators.

$$
\begin{aligned}
\alpha & =r_{6} a b c d+r_{5} b c d e+r_{4} a b c f+r_{3} a b e f+r_{2} a d e f+r_{1} c d e f \\
\beta & =s_{6} a b c d+s_{5} b c d e+s_{4} a b c f+s_{3} a b e f+s_{2} a d e f+s_{1} c d e f \\
\gamma & =t_{6} a b c d+t_{5} b c d e+t_{4} a b c f+t_{3} a b e f+t_{2} a d e f+t_{1} c d e f
\end{aligned}
$$

The resolution of $R /(\alpha, \beta, \gamma)$ is

$$
0 \longrightarrow R \xrightarrow{d_{6}} R^{6} \xrightarrow{d_{5}} R^{15} \xrightarrow{d_{4}} R^{20} \xrightarrow{\varphi_{3}} R^{12} \xrightarrow{\varphi_{2}} R^{3} \xrightarrow{\varphi_{1}} R
$$

where the $d_{i}$ 's are the Koszul maps on the variables $a, b, c, d, e, f$. We will describe the $\varphi_{i}$ 's later in this section. Here it is enough to notice that, except for the first several syzygy matrices and free modules, the resolution is the same as the resolution of the complete intersection $\left(x_{1}, \ldots, x_{n}\right)$. This pattern leads us to the following theorem.

Theorem 15. The ideal $G(n)$ is tail resolution equivalent to $\left(x_{1}, \ldots\right.$, $x_{n}$ ).

In order to prove this theorem, we will exhibit a resolution for $G(n)$. In the process we will show that it has the same tail as the Koszul resolution on $n$ variables.

Let the following complex be the Koszul resolution of $R /\left(x_{1}, \ldots, x_{n}\right)$.

$$
\mathcal{K}: 0 \longrightarrow \bigwedge^{n}\left(R^{n}\right) \xrightarrow{d_{n}} \cdots \xrightarrow{d_{4}} \bigwedge^{3}\left(R^{n}\right) \xrightarrow{d_{3}} \bigwedge^{2}\left(R^{n}\right) \xrightarrow{d_{2}} R^{n} \xrightarrow{d_{1}} R
$$

Let $G_{1}$ be the free submodule of $\bigwedge^{2}\left(R^{n}\right)$ generated by $\left\{x_{i} \wedge x_{i+1}\right.$, $1 \leq i \leq n\}$ and let $G_{2}$ be the complementary free submodule of $\bigwedge^{2}\left(R^{n}\right)$ generated by $\left\{x_{i} \wedge x_{j}\right.$ such that $i$ and $j$ are not adjacent integers modulo $n\}$. Recall that all subscripts on variables are to be considered modulo n. $G_{1}$ and $G_{2}$ determine maps $\psi_{1}: \bigwedge^{3}\left(R^{n}\right) \rightarrow G_{1}$ and $\psi_{2}: \bigwedge^{3}\left(R^{n}\right) \rightarrow G_{2}$ such that $d_{3}=\psi_{1} \oplus \psi_{2}$. Hence $\psi_{1}$ is given by an $n \times\binom{ n}{3}$ matrix and $\psi_{2}$ by an $\left(\binom{n}{2}-n\right) \times\binom{ n}{3}$ matrix. Now let $M: G_{1} \rightarrow R^{3}$ be given by the $3 \times n$ matrix

$$
\left(\begin{array}{llll}
r_{1} & r_{2} & \cdots & r_{n} \\
s_{1} & s_{2} & \cdots & s_{n} \\
t_{1} & t_{2} & \cdots & t_{n}
\end{array}\right)
$$

We define the map $\varphi_{3}: \bigwedge^{3} R^{n} \rightarrow R^{3} \oplus G_{2}$ to be $\binom{M \psi_{1}}{\psi_{2}}$.
We define the map $\varphi_{1}: \bigwedge^{2} R^{3} \simeq R^{3^{*}} \rightarrow R^{*}$ to be the composite of $M^{t}: R^{3^{*}} \simeq \bigwedge^{2} R^{3} \rightarrow G_{1}^{*}$ and $\mu: G_{1}^{*} \rightarrow R$ given by the matrix $\left(\mathbf{m}_{1,2} \mathbf{m}_{2,3} \cdots \mathbf{m}_{n, 1}\right)$. Recall $\mathbf{m}_{S}=\prod_{p \notin S} x_{p}$.

Let $K: \bigwedge^{2} R^{3 *} \rightarrow \bigwedge^{2} R^{3}$ be the matrix of Koszul syzygies on $\alpha, \beta$, and $\gamma$, the generators of $G(n)$. Let $P: G_{2} \rightarrow \bigwedge^{2} G_{1}$ be determined by the following map on the generators of $G_{2}$ :

$$
\begin{gathered}
x_{i} \wedge x_{j} \\
i<j-1
\end{gathered} \longmapsto \sum_{\substack{l \in\{i, \ldots, j-1\} \\
m \in\{1, \ldots, i-1, j, \ldots, n\}}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}}\left(x_{m} \wedge x_{m+1}\right) \wedge\left(x_{l} \wedge x_{l+1}\right)
$$

Note that the fraction $\left(\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}\right) / \mathbf{m}_{i, j}$ is, in fact, a ring element. Let $N: G_{2} \rightarrow R^{3^{*}}$ be the composite of $P$ and $\bigwedge^{2} M: \bigwedge^{2} G_{1} \rightarrow \bigwedge^{2} R^{3} \simeq$ $R^{3^{*}}$. Define $\varphi_{2}: R^{3} \oplus G_{2} \rightarrow \bigwedge^{2} R^{3} \simeq R^{3^{*}}$ to be $K$ on $R^{3}$ and $N$ on $G_{2}$, so $\varphi_{2}=(K \mid N)$.

Then the proposed resolution for $R / G(n)$ is

$$
\begin{aligned}
\mathcal{J}: 0 \longrightarrow \bigwedge^{n} R^{n} \xrightarrow{d_{n}} \cdots \xrightarrow{d_{4}} \bigwedge^{3} R^{n} \xrightarrow{\varphi_{3}} & R^{3} \oplus G_{2} \\
& \xrightarrow{\varphi_{2}} \bigwedge^{2} R^{3} \simeq R^{3^{*}} \xrightarrow{\varphi_{1}} R^{*} .
\end{aligned}
$$

Theorem 16. The sequence $\mathcal{J}$ described above is an exact complex.

This theorem provides a proof of Theorem 15.

Proof of Theorem 15. Theorem 16 shows that the complex $\mathcal{J}$ is a resolution. By its construction it is tail resolution equivalent to the ideal $\left(x_{1}, \ldots, x_{n}\right)$.

We will prove Theorem 16 in the next section.
4. Proof of Tail resolution equivalence. In the following two subsections, we prove Theorem 16 by first showing $\mathcal{J}$ is a complex and then showing that it is exact.

### 4.1 Proof of complex structure.

Lemma 17. The sequence $\mathcal{J}$ of Theorem 16 is a complex.

Proof. We show that $\mathcal{J}$ is a complex by checking that the composition of every pair of adjacent maps is zero. Notice that the maps $d_{i}$, for $4 \leq i \leq n$, are exactly the same as those in the Koszul resolution. Hence, all the compositions $d_{i} d_{i+1}$ for $4 \leq i<n$ are zero, and we are left with only three pairs of maps to check.

Consider $\varphi_{3} d_{4}$. The rows of $\varphi_{3}$ are either rows of $d_{3}$, or linear combinations of rows of $d_{3}$. Since $d_{3} d_{4}=0$, we get $\varphi_{3} d_{4}=0$.

There are two compositions left to check.
Lemma 18. $\varphi_{1} \varphi_{2}=0$.

Lemma 19. $\varphi_{2} \varphi_{3}=0$.

In the remainder of this section, we prove these lemmas and hence complete the proof that $\mathcal{J}$ is a complex.

Before we prove the lemmas, we describe the maps involved in more detail.

Let $\Delta_{p m l}$ be the $3 \times 3$ minor of $M$ using columns $p, m$, and $l$.
Let $\left\{g_{1}, g_{2}, g_{3}\right\}$ be a basis for $R^{3}$ and $\left\{h_{1}, h_{2}, h_{3}\right\}$ a basis for $R^{3^{*}}$.

$$
\begin{aligned}
& \varphi_{3}: \bigwedge^{3} R^{n} \longrightarrow R^{3} \oplus G_{2} \\
& x_{i} \wedge x_{j} \wedge x_{k} \longmapsto \sum_{l, m \text { s.t. }\{l, l+1, m\}=\{i, j, k\}}\left(r_{l} x_{m} g_{1}-s_{l} x_{m} g_{2}+t_{l} x_{m} g_{3}\right) \\
& +x_{i} x_{j} \wedge x_{k} \text {, if } k \neq j-1, j+1 \\
& +x_{j} x_{k} \wedge x_{i} \text {, if } i \neq k-1, k+1 \\
& +x_{k} x_{i} \wedge x_{j} \text {, if } j \neq i-1, i+1 \\
& P: G_{2} \longrightarrow \bigwedge^{2} G_{1} \\
& \begin{array}{c}
x_{i} \wedge x_{j} \\
i<j-1
\end{array} \sum_{\substack{i \leq l<j \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}}\left(x_{m} \wedge x_{m+1}\right) \wedge\left(x_{l} \wedge x_{l+1}\right) \\
& +\sum_{\substack{i \leq l<j \\
j \leq m \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}}\left(x_{m} \wedge x_{m+1}\right) \wedge\left(x_{l} \wedge x_{l+1}\right)
\end{aligned}
$$

$$
\begin{aligned}
\bigwedge^{2} M: \bigwedge^{2} G_{1} & \longmapsto \bigwedge^{2} R^{3} \simeq R^{3^{*}} \\
\left(x_{m} \wedge x_{m+1}\right) \wedge\left(x_{l} \wedge x_{l+1}\right) & \longmapsto\left(s_{m} t_{l}-s_{l} t_{m}\right) h_{1}-\left(r_{m} t_{l}-r_{l} t_{m}\right) h_{2} \\
& +\left(r_{m} s_{l}-r_{l} s_{m}\right) h_{3} \\
\mu M^{t} \bigwedge^{2} M: \bigwedge^{2} G_{1} & \longmapsto R^{*} \\
\left(x_{m} \wedge x_{m+1}\right) \wedge\left(x_{l} \wedge x_{l+1}\right) & \longmapsto \sum_{p=1}^{n} \Delta_{p m l} \mathbf{m}_{p, p+1} \\
m<l & \longmapsto \bigwedge_{i=1}^{2} R^{3} \simeq R^{3^{*}} \\
K: \bigwedge^{2} R^{3^{*}} & \longmapsto \sum_{i=1}^{n} t_{i} \mathbf{m}_{i, i+1} h_{2}-\sum_{i=1}^{n} s_{i} \mathbf{m}_{i, i+1} h_{3} \\
g_{2} & \longmapsto \sum_{i=1}^{n} t_{i} \mathbf{m}_{i, i+1} h_{1}-\sum_{i=1}^{n} r_{i} \mathbf{m}_{i, i+1} h_{3} \\
g_{3} & \longmapsto \sum_{i=1}^{n} s_{i} \mathbf{m}_{i, i+1} h_{1}-\sum_{i=1}^{n} r_{i} \mathbf{m}_{i, i+1} h_{2}
\end{aligned}
$$

Proof of Lemma 18. By definition of $K, \varphi_{1} K$ is zero. So, it is sufficient to show that $\varphi_{1} N=\left(\mu M^{t}\right)\left(\bigwedge^{2} M\right) P=0$.
Applying $P$ to a general element of $G_{2}$, we get

$$
x_{i} \wedge x_{j} \longmapsto \sum_{\substack{l \in\{i, \ldots, j-1\} \\ m \in\{1, \ldots, i-1, j, \ldots, n\}}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}}\left(x_{m} \wedge x_{m+1}\right) \wedge\left(x_{l} \wedge x_{l+1}\right)
$$

Under the map $\mu M^{t} \bigwedge^{2} M, P\left(x_{i} \wedge x_{j}\right)$ goes to

$$
\begin{aligned}
\sum_{m<i \leq l<j} & \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}} \sum_{p=1}^{n} \Delta_{p m l} \mathbf{m}_{p, p+1} \\
+ & \sum_{i \leq l<j \leq m} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}} \sum_{p=1}^{n} \Delta_{p m l} \mathbf{m}_{p, p+1}
\end{aligned}
$$

Letting $C_{p m l}=\left(\left(\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1} \mathbf{m}_{p}\right) / \mathbf{m}_{i, j}\right) \Delta_{p m l}$, the above expression can be rewritten as

$$
\begin{aligned}
&= \sum_{\substack{1 \leq m<i \\
i \leq l<j}} \sum_{\substack{ \\
i \leq p \leq n}} C_{p m l}+\sum_{\substack{i \leq l<j \\
j \leq m \leq n}} \sum_{\substack{1 \leq p \leq n}} C_{p m l} \\
&=\sum_{\substack{1 \leq m<i \\
i \leq l<j \\
1 \leq p<i}} C_{p m l}+\sum_{\substack{1 \leq m<i \\
i \leq l<j \\
i \leq p<j}} C_{p m l}+\sum_{\substack{1 \leq m<i \\
i \leq l<j \\
j \leq p \leq n}} C_{p m l}+\sum_{\substack{i \leq l<j \\
j \leq m \leq n \\
1 \leq p<i}} C_{p m l} \\
&+\sum_{\substack{i \leq l<j \\
j \leq m \leq n \\
i \leq p<j}} C_{p m l}+\sum_{\substack{i \leq l<j \\
j \leq m \leq n \\
j \leq p \leq n}} C_{p m l} .
\end{aligned}
$$

The first and last sums cancel with themselves as $\{p, m\}$ ranges over the specified values. The second and fifth sums cancel with themselves as $\{p, l\}$ ranges over the specified values. Since $C_{p m l}=-C_{m p l}$, the third and fourth sums cancel with each other. Hence this whole expression is zero.

Proof of Lemma 19. We want to show that $K M \psi_{1}+\left(\bigwedge^{2} M\right) N \psi_{2}=0$.
There are three possible forms for a basis element of $\bigwedge^{3} R^{n}$. We will treat each one separately.

Case 1. $x_{i} \wedge x_{i+1} \wedge x_{i+2}$. Under $\varphi_{3}$ this element maps to

$$
\begin{aligned}
r_{i} x_{i+2} g_{1}-s_{i} x_{i+2} g_{2} & +t_{i} x_{i+2} g_{3}+r_{i+1} x_{i} g_{1} \\
& -s_{i+1} x_{i} g_{2}+t_{i+1} x_{i} g_{3}-x_{i+1} x_{i} \wedge x_{i+2} \\
= & \left(r_{i} x_{i+2}+r_{i+1} x_{i}\right) g_{1}-\left(s_{i} x_{i+2}+s_{i+1} x_{i}\right) g_{2} \\
& +\left(t_{i} x_{i+2}+t_{i+1} x_{i}\right) g_{3}-x_{i+1} x_{i} \wedge x_{i+2}
\end{aligned}
$$

In turn, under $\varphi_{2}, \varphi_{3}\left(x_{i} \wedge x_{i+1} \wedge x_{i+2}\right)$ maps to

$$
\begin{aligned}
& \left(r_{i} x_{i+2}+r_{i+1} x_{i}\right)\left(\sum_{1 \leq \delta \leq n} t_{\delta} \mathbf{m}_{\delta, \delta+1} h_{2}-\sum_{1 \leq \delta \leq n} s_{\delta} \mathbf{m}_{\delta, \delta+1} h_{3}\right) \\
& -\left(s_{i} x_{i+2}+s_{i+1} x_{i}\right)\left(\sum_{1 \leq \delta \leq n} t_{\delta} \mathbf{m}_{\delta, \delta+1} h_{1}-\sum_{1 \leq \delta \leq n} r_{\delta} \mathbf{m}_{\delta, \delta+1} h_{3}\right) \\
& +\left(t_{i} x_{i+2}+t_{i+1} x_{i}\right)\left(\sum_{1 \leq \delta \leq n} s_{\delta} \mathbf{m}_{\delta, \delta+1} h_{1}-\sum_{1 \leq \delta \leq n} r_{\delta} \mathbf{m}_{\delta, \delta+1} h_{2}\right) \\
& -x_{i+1} \sum_{\substack{l=i, i+1 \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}} \\
& \times\left[\left(s_{m} t_{l}-s_{l} t_{m}\right) h_{1}-\left(r_{m} t_{l}-r_{l} t_{m}\right) h_{2}+\left(r_{m} s_{l}-r_{l} s_{m}\right) h_{3}\right] \\
& -x_{i+1} \sum_{\substack{l=i, i+1 \\
i+2 \leq m \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}} \\
& \times\left[\left(s_{m} t_{l}-s_{l} t_{m}\right) h_{1}-\left(r_{m} t_{l}-r_{l} t_{m}\right) h_{2}+\left(r_{m} s_{l}-r_{l} s_{m}\right) h_{3}\right] .
\end{aligned}
$$

The $h_{1}$ component is

$$
\begin{aligned}
-\left(s_{i} x_{i+2}+s_{i+1} x_{i}\right) & \sum_{1 \leq \delta \leq n} t_{\delta} \mathbf{m}_{\delta, \delta+1}+\left(t_{i} x_{i+2}+t_{i+1} x_{i}\right) \sum_{1 \leq \delta \leq n} s_{\delta} \mathbf{m}_{\delta, \delta+1} \\
& -x_{i+1} \sum_{\substack{l=i, i+1 \\
1 \leq m \leq i-1}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& -x_{i+1} \sum_{\substack{l=i, i+1 \\
i+2 \leq m \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}}\left(s_{m} t_{l}-s_{l} t_{m}\right)
\end{aligned}
$$

Rearranging this expression it becomes

$$
\begin{aligned}
& \sum_{1 \leq \delta \leq n}\left[\left(s_{\delta} t_{i+1}-s_{i+1} t_{\delta}\right)\right.\left.x_{i}+\left(s_{\delta} t_{i}-s_{i} t_{\delta}\right) x_{i+2}\right] \mathbf{m}_{\delta, \delta+1} \\
&- \sum_{\substack{l=i, i+1 \\
1 \leq m \leq i-1}} \\
&-\sum_{\substack{l=i, i+1 \\
i+2 \leq m \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}} x_{i+1}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \mathbf{m}_{m, i+2}
\end{aligned}
$$

The $i$ and $i+1$ terms of the first sum cancel with each other. So, now the first sum has two parts: those terms where $\delta \leq i-1$ and those terms where $\delta \geq i+2$. The other two sums can be broken up into terms where $l=i$ and terms where $l=i+1$. So, we now have

$$
\begin{aligned}
\sum_{1 \leq \delta \leq i-1} & {\left[\left(s_{\delta} t_{i+1}-s_{i+1} t_{\delta}\right) x_{i}+\left(s_{\delta} t_{i}-s_{i} t_{\delta}\right) x_{i+2}\right] \mathbf{m}_{\delta, \delta+1} } \\
& +\sum_{i+2 \leq \delta \leq n}\left[\left(s_{\delta} t_{i+1}-s_{i+1} t_{\delta}\right) x_{i}+\left(s_{\delta} t_{i}-s_{i} t_{\delta}\right) x_{i+2}\right] \mathbf{m}_{\delta, \delta+1} \\
& -\sum_{1 \leq m \leq i-1} \frac{\mathbf{m}_{i, i+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}} x_{i+1}\left(s_{m} t_{i}-s_{i} t_{m}\right) \\
& -\sum_{1 \leq m \leq i-1} \frac{\mathbf{m}_{i+1, i+2} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}} x_{i+1}\left(s_{m} t_{i+1}-s_{i+1} t_{m}\right) \\
& -\sum_{i+2 \leq m \leq n} \frac{\mathbf{m}_{i, i+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}} x_{i+1}\left(s_{m} t_{i}-s_{i} t_{m}\right) \\
& -\sum_{i+2 \leq m \leq n} \frac{\mathbf{m}_{i+1, i+2} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+2}} x_{i+1}\left(s_{m} t_{i+1}-s_{i+1} t_{m}\right)
\end{aligned}
$$

It is easy to see that $\left(\mathbf{m}_{i, i+1} x_{i+1}\right) / \mathbf{m}_{i, i+2}=x_{i+2}$ and $\left(\mathbf{m}_{i+1, i+2} x_{i+1}\right) /$ $\mathbf{m}_{i, i+2}=x_{i}$. Now we have

$$
\begin{aligned}
\sum_{1 \leq \delta \leq i-1} & {\left[\left(s_{\delta} t_{i+1}-s_{i+1} t_{\delta}\right) x_{i}+\left(s_{\delta} t_{i}-s_{i} t_{\delta}\right) x_{i+2}\right] \mathbf{m}_{\delta, \delta+1} } \\
& +\sum_{i+2 \leq \delta \leq n}\left[\left(s_{\delta} t_{i+1}-s_{i+1} t_{\delta}\right) x_{i}+\left(s_{\delta} t_{i}-s_{i} t_{\delta}\right) x_{i+2}\right] \mathbf{m}_{\delta, \delta+1} \\
& -\sum_{1 \leq m \leq i-1} \mathbf{m}_{m, m+1} x_{i+2}\left(s_{m} t_{i}-s_{i} t_{m}\right) \\
& +\sum_{i+2 \leq m \leq n} \mathbf{m}_{m, m+1} x_{i}\left(s_{i+1} t_{m}-s_{m} t_{i+1}\right) \\
& -\sum_{1 \leq m \leq i-1} \mathbf{m}_{m, m+1} x_{i}\left(s_{m} t_{i+1}-s_{i+1} t_{m}\right) \\
& +\sum_{i+2 \leq m \leq n} \mathbf{m}_{m, m+1} x_{i+2}\left(s_{i} t_{m}-s_{m} t_{i}\right)=0
\end{aligned}
$$

The $h_{2}$ and $h_{3}$ components can be similarly shown to be zero. So for Case 1, the composition of these maps is zero.

Case 2. $x_{i} \wedge x_{i+1} \wedge x_{k}$ where $x_{i} \wedge x_{k}$ and $x_{i+1} \wedge x_{k}$ are not part of the basis of $G_{1}$.

We may assume $i<k$ in order to simplify the calculations. Under $\varphi_{3} x_{i} \wedge x_{i+1} \wedge x_{k}$ maps to

$$
r_{i} x_{k} g_{1}-s_{i} x_{k} g_{2}+t_{i} x_{l} g_{3}+x_{i} x_{i+1} \wedge x_{k}-x_{i+1} x_{i} \wedge x_{k}
$$

In turn, under $\varphi_{2}$, this element goes to

$$
\begin{aligned}
& r_{i} x_{k}\left(\sum_{1 \leq \delta \leq n} t_{\delta} \mathbf{m}_{\delta, \delta+1} h_{2}-\sum_{1 \leq \delta \leq n} s_{\delta} \mathbf{m}_{\delta, \delta+1} h_{3}\right) \\
& -s_{i} x_{k}\left(\sum_{1 \leq \delta \leq n} t_{\delta} \mathbf{m}_{\delta, \delta+1} h_{1}-\sum_{1 \leq \delta \leq n} r_{\delta} \mathbf{m}_{\delta, \delta+1} h_{3}\right) \\
& +t_{i} x_{k}\left(\sum_{1 \leq \delta \leq n} s_{\delta} \mathbf{m}_{\delta, \delta+1} h_{1}-\sum_{1 \leq \delta \leq n} r_{\delta} \mathbf{m}_{\delta, \delta+1} h_{2}\right) \\
& +x_{i} \sum_{\substack{i+1 \leq l<k \\
1 \leq m<i+1}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i+1, k}} \\
& \times\left[\left(s_{m} t_{l}-s_{l} t_{m}\right) h_{1}-\left(r_{m} t_{l}-r_{l} t_{m}\right) h_{2}+\left(r_{m} s_{l}-r_{l} s_{m}\right) h_{3}\right] \\
& -x_{i} \sum_{\substack{i+1 \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i+1, k}} \\
& \times\left[\left(s_{m} t_{l}-s_{l} t_{m}\right) h_{1}-\left(r_{m} t_{l}-r_{l} t_{m}\right) h_{2}+\left(r_{m} s_{l}-r_{l} s_{m}\right) h_{3}\right] \\
& -x_{i+1} \sum_{\substack{i \leq l<k \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, k}} \\
& \times\left[\left(s_{m} t_{l}-s_{l} t_{m}\right) h_{1}-\left(r_{m} t_{l}-r_{l} t_{m}\right) h_{2}+\left(r_{m} s_{l}-r_{l} s_{m}\right) h_{3}\right] \\
& +x_{i+1} \sum_{\substack{i \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, k}} \\
& \times\left[\left(s_{m} t_{l}-s_{l} t_{m}\right) h_{1}-\left(r_{m} t_{l}-r_{l} t_{m}\right) h_{2}+\left(r_{m} s_{l}-r_{l} s_{m}\right) h_{3}\right] .
\end{aligned}
$$

Taking just the coefficient of $h_{1}$, we get

$$
\begin{aligned}
& \sum_{1 \leq \delta \leq n}\left(s_{\delta} t_{i}-s_{i} t_{\delta}\right) x_{k} \mathbf{m}_{\delta, \delta+1} \\
& \quad+x_{i} \sum_{\substack{i+1 \leq l<k \\
1 \leq m<i+1}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i+1, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad-x_{i} \sum_{\substack{i+1 \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i+1, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad-x_{i+1} \sum_{\substack{i \leq l<k \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad+x_{i+1} \sum_{\substack{i \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right)
\end{aligned}
$$

Remove the terms where $m=1$ or $l=1$ from the second, fourth, and fifth sums above. Then notice that $\left[\left(\mathbf{m}_{i, i+1} x_{i+1}\right) / \mathbf{m}_{i, k}\right]\left[\left(\mathbf{m}_{i, i+1} x_{i}\right) /\right.$ $\left.\mathbf{m}_{i+1, k}\right]=x_{k}$ and rewrite the above expression as

$$
\begin{aligned}
& \sum_{1 \leq \delta \leq n}\left(s_{\delta} t_{i}-s_{i} t_{\delta}\right) x_{k} \mathbf{m}_{\delta, \delta+1}+\sum_{\substack{i+1 \leq l<k \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+1, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad-\sum_{\substack{i+1 \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+1, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad-\sum_{\substack{i<l<k \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+1, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad+\sum_{\substack{i<m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, i+1, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right)+\sum_{i+1 \leq l<k} \mathbf{m}_{l, l+1} x_{k}\left(s_{i} t_{l}-s_{l} t_{i}\right) \\
& \quad-\sum_{1 \leq m<i} \mathbf{m}_{m, m+1} x_{k}\left(s_{m} t_{i}-s_{i} t_{m}\right)+\sum_{k \leq l \leq n} \mathbf{m}_{l, l+1} x_{k}\left(s_{i} t_{l}-s_{l} t_{i}\right)
\end{aligned}
$$

So we see that the sum is zero, as desired. The calculations for the $h_{2}$ and $h_{3}$ components similarly yield zero.

Case 3. $x_{i} \wedge x_{j} \wedge x_{k}$ where no pair among $x_{i}, x_{j}$, and $x_{k}$ form a basis element of $G_{1}$.

Again we write down the image of this element under the map $\varphi_{3}$ followed by $\varphi_{2}$ and then take the coefficient of $h_{1}$. We will assume $i<j<k$. In this case, we get

$$
\begin{aligned}
& x_{i} \sum_{\substack{j \leq l<k \\
1 \leq m<j}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& -x_{i} \sum_{\substack{j \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad-x_{j} \sum_{\substack{i \leq l<k \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad+x_{j} \sum_{\substack{i \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} b f m_{m, m+1}}{\mathbf{m}_{i, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& \quad+x_{k} \sum_{\substack{i \leq l<j \\
1 \leq m<i}}^{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}} \\
& \mathbf{m}_{i, j} \\
& \left.m_{m} t_{l}-s_{l} t_{m}\right) \\
& -x_{k} \sum_{\substack{i \leq m<j \\
j \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}}\left(s_{m} t_{l}-s_{l} t_{m}\right) .
\end{aligned}
$$

The expression simplifies to

$$
\begin{aligned}
\sum_{\substack{j \leq l<k \\
1 \leq m<j}} & \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& -\sum_{\substack{j \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& -\sum_{\substack{i \leq l<k \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& +\sum_{\substack{i \leq m<k \\
k \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right)
\end{aligned}
$$

$$
\begin{aligned}
& +\sum_{\substack{i \leq l<j \\
1 \leq m<i}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right) \\
& -\sum_{\substack{i \leq m<j \\
j \leq l \leq n}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j, k}}\left(s_{m} t_{l}-s_{l} t_{m}\right)
\end{aligned}
$$

Now we can see that everything cancels. The fifth sum cancels the terms of the third sum where $i \leq l<j$. The remaining terms of the third sum, those where $j \leq l<k$, cancel with the terms of the terms of the first sum where $m<i$. The remaining terms of the first sum, those where $i \leq m<j$, cancel with the terms of the sixth sum where $j \leq l<k$. The remaining terms of the sixth sum, those where $k \leq l \leq n$, cancel with the terms of the fourth sum where $i \leq m<j$. The remaining terms of the fourth sum, those where $j \leq m \leq k$, cancel with the entire second sum.

The calculations for the $h_{2}$ and $h_{3}$ components similarly yield zero and so the composition of these maps is zero as desired.
4.2 Proof of exactness. Recall that the complex $\mathcal{K}$ is the Koszul resolution of $R /\left(x_{1}, \ldots, x_{n}\right)$. Let $A_{i}$ be the matrix of the map $d_{i}$ with respect to the usual bases. In particular, we denote the rows of $A_{3}$ corresponding to generators of $G_{1}$ by $y_{1}, \ldots, y_{n}$ and the rows of $A_{3}$ corresponding to generators of $G_{2}$ by $y_{n+1}, \ldots, y_{\binom{n}{2}}$.

The complex $\mathcal{K}$ satisfies the conditions of Corollary 6 so we may simultaneously factor the matrices $\bigwedge^{\text {rank } A_{i}} A_{i}$. In order to calculate the minors of $A_{3}$, we describe the first three steps in the complete factorization of $\mathcal{K}$.

$$
\begin{aligned}
& \left(\bigwedge^{\operatorname{rank} A_{1}} A_{1}\right)_{1, j}=x_{j} \\
& \left(\bigwedge^{\operatorname{rank} A_{2}} A_{2}\right)_{I, J}=\left(a_{1}\right)_{I}\left(a_{2}\right)_{J} \text { where }\left(a_{1}\right)_{I}=\operatorname{sgn}\left(I, I^{\prime}\right) x_{I^{\prime}}
\end{aligned}
$$

and

$$
\left(\bigwedge^{\text {rank } A_{3}} A_{3}\right)_{L, N}=\left(a_{2}^{\prime}\right)_{L}\left(a_{3}\right)_{N} \text { where }\left(a_{2}^{\prime}\right)_{L}=\operatorname{sgn}\left(L, L^{\prime}\right)\left(a_{2}\right)_{L^{\prime}}
$$

Choose $i \in\{1, \ldots, n\}$. Let $L=\left\{i, n+1, \ldots,\binom{n}{2}\right\}$. So $L^{\prime}=$ $\{1, \ldots, n\} \backslash\{i\}$. If $I=\{1, \ldots, n\} \backslash\{i\}$, we have that $\left(\bigwedge^{\mathrm{rank} A_{2}} A_{2}\right)_{I, L^{\prime}}$
is the determinant of the matrix

$$
\left(\begin{array}{ccccc}
-x_{2} & 0 & 0 & \ldots & x_{n} \\
x_{1} & -x_{3} & 0 & \ldots & 0 \\
0 & x_{2} & -x_{4} & \ldots & 0 \\
0 & 0 & x_{3} & \ldots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \ldots & -x_{1}
\end{array}\right)
$$

with the $i$ th row and column removed. Since $\left(a_{1}\right)_{I}=x_{i},\left(\bigwedge^{\text {rank } A_{2}} \times\right.$ $\left.A_{2}\right)_{I, L^{\prime}}=(-1)^{n-1} \mathbf{m}_{i, i+1} x_{i}$. So $\left(a_{2}^{\prime}\right)_{L}=\operatorname{sgn}\left(L, L^{\prime}\right)\left(a_{2}\right)_{L^{\prime}}=\operatorname{sgn}\left(L, L^{\prime}\right) \times$ $(-1)^{n-1} \mathbf{m}_{i, i+1}$. Then for any choice of $\binom{n}{2}-n+1$ columns $N$ of $A_{3}$, we have that $\left(\bigwedge^{\operatorname{rank} A_{3}} A_{3}\right)_{L, N}=\operatorname{sgn}\left(L, L^{\prime}\right)(-1)^{n-1} \mathbf{m}_{i, i+1}\left(a_{3}\right)_{N}$.

$$
\text { Let } \lambda=\binom{n}{2}-n+1 .
$$

Lemma 20. $\operatorname{codim}\left(I_{\lambda}\left(\varphi_{3}\right)\right) \geq 2$ and $\operatorname{rank}\left(\varphi_{3}\right)=\lambda$.

Proof. Let the rows of $\varphi_{3}$ be $z_{1}, \ldots, z_{\lambda+2}$ where the first three rows are $\sum_{1 \leq i \leq n} r_{i} y_{i} \sum_{1 \leq i \leq n} s_{i} y_{i}, \sum_{1 \leq i \leq n} t_{i} y_{i}$, and the remaining $\lambda-1$ rows are $y_{n+1}, \ldots y_{\binom{n}{2}}$.

Take $K$ to be $\{1,4,5, \ldots, \lambda+2\}$. Then by multilinearity

$$
\begin{aligned}
\left(\bigwedge^{\lambda} \varphi_{3}\right)_{K, N} & =\sum_{1 \leq i \leq n} r_{i} \operatorname{det}\left(\begin{array}{c}
y_{i} \\
y_{n+1} \\
\vdots \\
y_{\binom{n}{2}}
\end{array}\right)_{N}=\sum_{1 \leq i \leq n} r_{i}\left(\bigwedge^{\operatorname{rank} A_{3}} A_{3}\right)_{L, N} \\
& =\sum_{1 \leq i \leq n} \operatorname{sgn}\left(L, L^{\prime}\right)(-1)^{n-1} r_{i} \mathbf{m}_{i, i+1}\left(a_{3}\right)_{N}
\end{aligned}
$$

for any subset $N$ of size $\lambda$ and $L=\left\{i, n+1, \ldots,\binom{n}{2}\right\}$.
Similarly, if we take $K=\{2,4,5, \ldots, \lambda+2\}$ and $K=\{3,4,5, \ldots$, $\lambda+2\}$, we get

$$
\left(\bigwedge^{\lambda} \varphi_{3}\right)_{K, N}=\sum_{1 \leq i \leq n} \operatorname{sgn}\left(L, L^{\prime}\right)(-1)^{n} s_{i} \mathbf{m}_{i, i+1}\left(a_{3}\right)_{N}
$$

and

$$
\left(\bigwedge^{\lambda} \varphi_{3}\right)_{K, N}=\sum_{1 \leq i \leq n} \operatorname{sgn}\left(L, L^{\prime}\right)(-1)^{n-1} t_{i} \mathbf{m}_{i, i+1}\left(a_{3}\right)_{N}
$$

respectively, for any choice of $N$.
If $\operatorname{codim}\left(I_{\lambda}\left(\varphi_{3}\right)\right)=1$, then the $\left(\bigwedge^{\lambda} \varphi_{3}\right)_{K, N}$ over all $K$ and $N$ must have a common factor. Hence $\left\{\left(a_{3}\right)_{N}\right\}$ over all choices for $N$ must have a common factor. This leads to a contradiction because the ideal generated by all the $\left(a_{3}\right)_{N}$ is of codimension $n$.

We know there must be an $N$ such that $\left(a_{3}\right)_{N} \neq 0$, so we have also found a nonzero $\lambda \times \lambda$ minor of $\varphi_{3}$. By construction, the rank of $\varphi_{3}$ cannot be larger than $\lambda$, therefore it is equal to $\lambda$.

Now we are prepared to prove the following lemma.

Lemma 21. The complex $\mathcal{J}$ of Theorem 16 is exact.

We will show the complex $\mathcal{J}$ is exact by applying the BuchsbaumEisenbud exactness theorem (Theorem 2).

Proof. We know that all the conditions of Theorem 2 are satisfied for $k \geq 4$ because the tail of the complex is the same as the tail of the Koszul resolution of $n$ variables. It remains to be shown that the conditions hold for $k=1,2$, and 3 .

Claim. $\operatorname{rank}\left(\varphi_{1}\right)+\operatorname{rank}\left(\varphi_{2}\right)=\operatorname{rank}\left(R^{3}\right)$.
Since $M \neq 0$, $\operatorname{rank}\left(\varphi_{1}\right)=\operatorname{rank}(\alpha \beta \gamma)=1$. So, we just need to show that rank $\varphi_{2}=2$. The sum of the ranks of the maps is always less than or equal to the rank of the module. So, we know that $\operatorname{rank}\left(\varphi_{2}\right) \leq 3-1=2$. To show equality, we just need to find a $2 \times 2$ submatrix with nonzero determinant. Since $\varphi_{2}$ includes the $3 \times 3$ Koszul matrix, it also contains a $2 \times 2$ submatrix with nonzero determinant, namely the product of two generators of the 3 -generated ideal.

Claim. $\operatorname{rank}\left(\varphi_{2}\right)+\operatorname{rank}\left(\varphi_{3}\right)=\operatorname{rank}\left(R^{3} \oplus G_{2}\right)$.

From above, we know that $\operatorname{rank}\left(\varphi_{2}\right)=2$. Lemma 20 shows that $\operatorname{rank}\left(\varphi_{3}\right)=\binom{n}{2}-n+1$ and we know that $\operatorname{rank}\left(R^{3} \oplus G_{2}\right)=3+\binom{n}{2}-n$.

Claim. $\operatorname{rank}\left(\varphi_{3}\right)+\operatorname{rank}\left(d_{4}\right)=\operatorname{rank}\left(\bigwedge^{3} R^{n}\right)$.
The rank of $d_{4}$ is $\binom{n}{3}-\binom{n}{2}+n-1$ because it is part of the Koszul complex, which is exact. We showed above that $\operatorname{rank} \varphi_{3}=\binom{n}{2}-n+1$. So rank $\varphi_{3}+\operatorname{rank}\left(d_{4}\right)=\binom{n}{2}-n+1+\binom{n}{3}-\binom{n}{2}+n-1=\binom{n}{3}=$ $\operatorname{rank}\left(\bigwedge^{3} R^{n}\right)$.

Claim. $\operatorname{codim}\left(I\left(\varphi_{1}\right)\right) \geq 1$.
We know $\operatorname{rank}\left(\varphi_{1}\right)=1$ so $I\left(\varphi_{1}\right)$ is generated by the entries of $\varphi_{1}$. Since $M \neq 0$, this ideal is nonzero and so its codimension must be at least one.

Claim. $\operatorname{codim}\left(I\left(\varphi_{2}\right)\right) \geq 2$.
The rank of $\varphi_{2}$ is 2 , so $I\left(\varphi_{2}\right)=I_{2}\left(\varphi_{2}\right)$. The map given by the matrix $K$ is the Koszul relations on $\alpha, \beta$, and $\gamma$, so the $2 \times 2$ minors of it (and hence also of $\varphi_{2}$ ) contain the ideal $\left(\alpha^{2}, \beta^{2}, \gamma^{2}\right)$. So $\operatorname{codim}\left(I\left(\varphi_{2}\right)\right) \geq$ $\operatorname{codim}\left(\alpha^{2}, \beta^{2}, \gamma^{2}\right)$. Since $\operatorname{codim}\left(\alpha^{2}, \beta^{2}, \gamma^{2}\right)=\operatorname{codim}(\alpha, \beta, \gamma)=2$, we have that $\operatorname{codim}\left(I_{2}\left(\varphi_{2}\right)\right) \geq 2$.

Claim. $\operatorname{codim}\left(I\left(\varphi_{3}\right)\right) \geq 3$.
Choose bases for $F_{i}$. Let $A_{i}$ be the matrix of the map $d_{i}$ for $i \geq 4$, and let $A_{i}$ be the matrix of the map $\varphi_{i}$ for $1 \leq i \leq 3$. Since the Koszul resolution is exact, by Theorem $2 \operatorname{codim}\left(I\left(d_{i}\right)\right) \geq i$ for $i \geq 4$. By Lemma $20 \operatorname{codim}\left(I\left(\varphi_{3}\right)\right) \geq 2$. We showed above that $\operatorname{codim}\left(I\left(\varphi_{2}\right)\right) \geq 2$. So by application of Corollary 6 to $\mathcal{J}$, there are ideals $B_{i}$ such that $I\left(d_{4}\right)=B_{5} B_{4}, I\left(\varphi_{3}\right)=B_{4} B_{3}, I\left(\varphi_{2}\right)=B_{3} B_{2}$, and $I\left(\varphi_{1}\right)=B_{2} B_{1}$. The ideal $I\left(\varphi_{1}\right)$ must have trivial complete factorization, so $B_{1}=(1)$ and $B_{2}=J$.

The codimension of a product of ideals is the minimum of the codimension of the factors. Since $\operatorname{codim}\left(I\left(\varphi_{4}\right)\right) \geq 4$, we also know that $\operatorname{codim}\left(B_{4}\right) \geq 4$. Therefore we would be done if we could show that $\operatorname{codim}\left(B_{3}\right) \geq 3$, and since $\operatorname{codim}\left(I\left(\varphi_{3}\right)\right) \geq 2$, we just need to show that codim $\left(B_{3}\right) \neq 2$.

Suppose that codim $\left(B_{3}\right)=2$. Then there is a codimension 2 prime $P$ such that $B_{3} \subset P$. By construction, $B_{3}$ contains $J$ and the entries of $N$. Therefore $P$ is a codimension 2 component of $J$. Hence, by Proposition 11, $P=\left(x_{i}, x_{j}\right)$ for some nonadjacent integers modulo $n i$ and $j$. Consider an entry of $N$ in the $x_{i} \wedge x_{j}$ column,

$$
\sum_{\substack{l \in \mathcal{I} \\ m \in \mathcal{I}^{c}}} \frac{\mathbf{m}_{l, l+1} \mathbf{m}_{m, m+1}}{\mathbf{m}_{i, j}}\left(s_{m} t_{l}-s_{l} t_{m}\right)
$$

If $s_{i} t_{j}-s_{j} t_{i} \neq 0$, then the term of the sum where $l=i$ and $m=j$ is nonzero. In fact, this term is $\mathbf{m}_{i+1, j+1}\left(s_{i} t_{j}-s_{j} t_{i}\right)$. None of the other terms can possibly cancel with this term and so the sum is not contained in the ideal $P$. This is a contradiction. Therefore $\operatorname{codim}\left(B_{3}\right) \geq 3$ and so $\operatorname{codim}\left(I\left(\varphi_{3}\right)\right) \geq 3$.

## 5. A menagerie of binomial ideals.

5.1 Specializations. The family of ideals above have generic coefficients so, for almost all specializations, the resolution is still exact. One wonders whether it is possible to specialize these coefficients to get binomial ideals tail resolution equivalent to $\left(x_{1}, \ldots, x_{n}\right)$. For projective dimension less than seven, it is possible as the following examples show.

Example 22 (Projective dimension 4). This example is the resolution for 4 variables with the specialization that $r_{3}=r_{4}=s_{1}=s_{4}=$ $t_{1}=t_{2}=0$, giving that the generators of the ideal are

$$
\begin{aligned}
\alpha & =r_{1} c d+r_{2} a d, \\
\beta & =s_{2} a d+s_{3} a b, \quad \text { and } \\
\gamma & =t_{3} a b+t_{4} b c
\end{aligned}
$$

and the resolution of $R /(\alpha, \beta, \gamma)$ has the form

$$
0 \longrightarrow R \xrightarrow{d_{4}} R^{4} \xrightarrow{\varphi_{3}} R^{6} \xrightarrow{\varphi_{2}} R^{3} \xrightarrow{\varphi_{1}} R
$$

where

$$
\varphi_{1}=\left(\begin{array}{lll}
\alpha & \beta & \gamma
\end{array}\right)
$$

and

$$
\varphi_{2}=\left(\begin{array}{ccccc}
0 & \gamma & \beta & * & * \\
\gamma & 0 & -\alpha & * & * \\
-\beta & -\alpha & 0 & * & *
\end{array}\right)
$$

The missing entries denoted by $*$ are polynomials of degree 2 in the variables and degree 2 in the coefficients.

$$
\varphi_{3}=\left(\begin{array}{cccc}
r_{2} a+r_{1} c & r_{1} d & 0 & r_{2} d \\
-s_{2} a & 0 & -s_{3} a & -s_{3} b-s_{2} d \\
0 & t_{4} b & t_{3} a+t_{4} c & t_{3} b \\
-b & 0 & d & 0 \\
0 & a & 0 & -c
\end{array}\right)
$$

Example 23 (Projective dimension 5). This example is the resolution for 5 variables with the specialization that $r_{2}=r_{3}=r_{5}=s_{1}=$ $s_{3}=s_{4}=t_{1}=t_{2}=t_{4}=0$, giving that the generators of the ideal are

$$
\begin{aligned}
\alpha & =r_{1} c d e+r_{4} a b c, \\
\beta & =s_{2} a d e+s_{5} b c d, \quad \text { and } \\
\gamma & =t_{3} a b e+t_{5} b c d,
\end{aligned}
$$

and the resolution of $R /(\alpha, \beta, \gamma)$ has the form

$$
0 \longrightarrow R \xrightarrow{d_{5}} R^{5} \xrightarrow{d_{4}} R^{10} \xrightarrow{\varphi_{3}} R^{8} \xrightarrow{\varphi_{2}} R^{3} \xrightarrow{\varphi_{1}} R
$$

where

$$
\varphi_{1}=\left(\begin{array}{lll}
\alpha & \beta & \gamma
\end{array}\right)
$$

and

$$
\varphi_{2}=\left(\begin{array}{cccccccc}
0 & \gamma & \beta & * & * & * & * & * \\
\gamma & 0 & -\alpha & * & * & * & * & * \\
-\beta & -\alpha & 0 & * & * & * & * & *
\end{array}\right)
$$

The missing entries denoted by $*$ are polynomials of degree 3 in the variables and degree 2 in the coefficients.
$\varphi_{3}=\left(\begin{array}{cccccccccc}r_{1} c & r_{1} d & r_{1} e & 0 & 0 & r_{4} a & 0 & 0 & r_{4} b & r_{4} c \\ -s_{2} a & 0 & -s_{5} b & 0 & -s_{5} c & -s_{5} d & -s_{2} d & -s_{2} e & 0 & 0 \\ 0 & & t_{5} b & t_{3} a & t_{5} c & t_{5} d & t_{3} b & 0 & 0 & t_{3} e \\ -b & 0 & 0 & d & e & 0 & 0 & 0 & 0 & 0 \\ 0 & -b & 0 & -c & 0 & e & 0 & 0 & 0 & 0 \\ 0 & a & 0 & 0 & 0 & 0 & -c & 0 & e & 0 \\ 0 & 0 & a & 0 & 0 & 0 & 0 & -c & -d & 0 \\ 0 & 0 & 0 & 0 & a & 0 & 0 & b & 0 & -d\end{array}\right)$.

Example 24 (Projective dimension 6). This example is the resolution for 6 variables with the specialization that $r_{2}=r_{3}=r_{5}=r_{6}=$ $s_{1}=s_{3}=s_{4}=s_{6}=t_{1}=t_{2}=t_{4}=t_{5}=0$ giving that the generators of the ideal are

$$
\begin{aligned}
\alpha & =r_{1} c d e f+r_{4} a b c f \\
\beta & =s_{2} a d e f+s_{5} a b c d \\
\gamma & =t_{3} a b e f+t_{6} b c d e
\end{aligned}
$$

and the resolution of $R /(\alpha, \beta, \gamma)$ has the form

$$
0 \longrightarrow R \xrightarrow{d_{6}} R^{6} \xrightarrow{d_{5}} R^{15} \xrightarrow{d_{4}} R^{20} \xrightarrow{\varphi_{3}} R^{12} \xrightarrow{\varphi_{2}} R^{3} \xrightarrow{\varphi_{1}} R
$$

where

$$
\varphi_{1}=\left(\begin{array}{lll}
\alpha & \beta & \gamma
\end{array}\right)
$$

and

$$
\varphi_{2}=\left(\begin{array}{cccccccccccc}
0 & \gamma & \beta & * & * & * & * & * & * & * & * & * \\
\gamma & 0 & -\alpha & * & * & * & * & * & * & * & * & * \\
-\beta & -\alpha & 0 & * & * & * & * & * & * & * & * & *
\end{array}\right)
$$

The missing entries denoted by $*$ are polynomials of degree 4 in the variables and degree 2 in the coefficients.

The matrix $\varphi_{3}$ is formed of two parts $\left(\frac{A}{B}\right)$ where

$$
\begin{aligned}
& A=\left(\begin{array}{cccccc}
r_{1} & 0 & 0 & r_{4} & 0 & 0 \\
0 & 0 & t_{3} & 0 & 0 & t_{6} \\
0 & s_{2} & 0 & 0 & s_{5} & 0
\end{array}\right) \\
& \times\left(\begin{array}{cccccccccccccccccccc}
c & d & e & f & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
a & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & d & e & f & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -a & 0 & 0 & 0 & 0 & 0 & -b & 0 & 0 & 0 & 0 & 0 & -e & f & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & a & 0 & 0 & 0 & 0 & 0 & b & 0 & 0 & c & 0 & 0 & -f \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -a & 0 & 0 & 0 & 0 & 0 & -b & 0 & 0 & -c & -d \\
0 & 0 & 0 & -b & 0 & 0 & c & 0 & d & e & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{array}\right)
\end{aligned}
$$

and
5.2 Random examples. For projective dimension 7 , none of the possible simple specializations, that is, setting some of the coefficients to be zero, of resolutions above give a resolution with the desired tail. In fact, they do not even give a projective dimension 7 resolution. So we were led to ask whether projective dimension 7 and higher binomial resolutions exist. Finding such resolutions turns out to be
a daunting task. We searched for examples by checking millions of randomly produced 3 -generated binomial ideals using Macaulay 2 [13]. The result was a number of examples having projective dimension 7 and a few having projective dimension 8 . We display one of each below. The remainder may be found in [12].

Here is the projective dimension 7 ideal having the smallest number of variables and degrees of generators of the ones we found. It has 7 variables and generators of degree 8 .

$$
\begin{aligned}
\alpha & =a^{3} c^{3} d f+a b^{2} c e g^{3} \\
\beta & =a c^{2} d f g^{3}+b^{2} e^{2} f g^{3} \\
\gamma & =a^{3} b^{2} c d e+b^{3} d^{2} e f g
\end{aligned}
$$

This ideal has degree 28, regularity 18 and its resolution has the form

$$
0 \longrightarrow R \longrightarrow R^{7} \longrightarrow R^{22} \longrightarrow R^{39} \longrightarrow R^{39} \longrightarrow R^{18} \longrightarrow R^{3} \longrightarrow R .
$$

Here the projective dimension 8 ideal is found having the smallest number of variables and degrees of generators. It has 10 variables and generators of degree 15 .

$$
\begin{aligned}
\alpha & =a c^{3} d^{3} f^{2} g h i^{4}+b c^{2} d^{3} e g^{2} h i^{3} j^{2} \\
\beta & =b^{3} c^{2} e f g^{2} h i^{3} j^{2}+a^{2} b^{4} d^{2} f^{2} i j^{4} \\
\gamma & =a^{3} c^{3} d e f^{3} g^{3} h+a^{4} b^{3} e f^{3} g h i j .
\end{aligned}
$$

This ideal has degree 103, regularity 40 and its resolution has the form

$$
\begin{aligned}
0 \longrightarrow R \longrightarrow R^{10} \longrightarrow R^{42} \longrightarrow R^{96} \longrightarrow R^{130} & \longrightarrow R^{100} \\
& \longrightarrow R^{35} \longrightarrow R^{3} \longrightarrow R .
\end{aligned}
$$

A projective dimension 9 3-generated binomial ideal has not yet been found. It is unknown whether or not it exists. Further searching could prove fruitful. Another approach, in the manner of Kohn's method in [14], would be to try to find a way to reduce the number of generators while preserving their binomial nature and the projective dimension of the ideal.
6. Further directions. The method of this paper for finding ideals tail resolution equivalent to the ideal $\left(x_{1}, \ldots, x_{n}\right)$ leads to a number of other questions about tail resolution equivalent ideals. For instance, are there conditions on an ideal that ensure that a 3-generated tail resolution equivalent ideal with monomial or binomial or certain degree generators exists? Is it always possible to find representatives of a tail resolution equivalence class which are generated by binomials? What about ones generated by monomials?

There are also open questions about the particular construction used to generate $G(n)$. Is it possible to extend this method to all complete intersections or is there something special about the ideal of $n$ variables? Perhaps understanding better the relation between the graphs and the ideals would lead to a more general method. We could also try starting with other graphs. Initial investigations into creating ideals from other graphs, however, were not promising. Also, what if we use this process for constructing 3-generated ideals on some other ideal and end up with a sequence that is not exact? Would the homology of this sequence tell us anything interesting about the ideal or the method?

Acknowledgments. The author thanks Mike Stillman for all his advice and patience while she was finishing her dissertation. She also thanks André Galligo and everyone in Nice for their kindness during her visit in which she started this project. Finally, thanks to Hal Schenck for encouragement and proofreading.
