LATTICES, ALGEBRAS AND BAIRE'S SYSTEMS  
 GENERATED BY SOME FAMILIES OF FUNCTIONS

I. Preliminaries. Let us establish some of the terminology to be used.  $R$  denotes the real line. Let  $(X, T)$  be a topological space. A function  $f: X \rightarrow R$  is said to be  $T$ -quasi-continuous at a point  $x_0 \in X$  iff for every  $\varepsilon > 0$  and for any neighbourhood  $U \in T$  of the point  $x_0$  there exists a  $T$ -open set  $V$  such that  $0 \neq V \subset U$  and  $|f(x) - f(x_0)| < \varepsilon$  for every  $x \in V$ ,  $T$ -cliquish at  $x_0 \in X$  iff for every  $\varepsilon > 0$  and for any neighbourhood  $U \in T$  of the point  $x_0$  there exists a  $T$ -open set  $V$  such that  $0 \neq V \subset U$  and  $|f(x) - f(x_1)| < \varepsilon$  for  $x, x_1 \in V$ .

A function  $f: X \rightarrow R$  is  $T$ -quasi-continuous ( $T$ -cliquish) on  $X$  iff  $f$  is  $T$ -quasi-continuous ( $T$ -cliquish) at every point of  $X$ .

Let  $X = R^m$ . We shall use the following differentiation basis. For every  $k \in N$  ( $N$  denotes the set of all positive integers) let  $P_k$  be the family of all  $m$ -dimensional intervals of the form

$$\langle i_1 - 1/2^k, i_1/2^k \rangle \times \dots \times \langle i_m - 1/2^k, i_m/2^k \rangle$$

where  $i_1, i_2, \dots, i_m = 0, \pm 1, \pm 2, \dots$ .

Let  $\mathcal{P} = \bigcup_{k=1}^{\infty} P_k$ . Let  $A \subset \mathbb{R}^m$  be a set. For  $x \in \mathbb{R}^m$  we can define the upper outer density of  $A$  at a point  $x$  by

$$\bar{d}(A, x) = \overline{\lim}_{\substack{P \Rightarrow x \\ P \in \mathcal{P}}} |A \cap P|/|P| ,$$

where  $|A|$  denotes  $m$ -dimensional Lebesgue outer measure of  $A$  and the understanding of the symbol  $P \Rightarrow x$  is that  $x \in P$  and the diameter of  $P$  tends to zero.

Denote by  $T_{\bullet}$  the Euclidean topology in  $\mathbb{R}^m$  and by  $d_2$  the density topology relative to the differentiation basis  $(P, \Rightarrow)$ .

The symbols  $Q_T, Cq_T$  stand for the family of all  $T$ -quasi-continuous functions  $f: \mathbb{R}^m \rightarrow \mathbb{R}$  and the family of all  $T$ -cliquish functions, respectively. Evidently we have  $Q_T \subset Cq_T$ .

If  $K$  is a family of functions  $f: X \rightarrow \mathbb{R}$  then

- (i)  $A(K)$  denotes the algebra generated by  $K$ , i.e. the least family for which:  $K \subset A(K)$ ,  $f+g \in A(K)$ ,  $f \cdot g \in A(K)$  for any  $f, g \in A(K)$  ;
- (ii)  $B(K)$  denotes the collection of all pointwise limits of sequences taken from  $K$  ;
- (iii)  $L(K)$  denotes the lattice generated by  $K$ , i.e. the least family for which  $\max(f, g) \in L(K)$  and  $\min(f, g) \in L(K)$  for any  $f, g \in L(K)$ .

Let  $(w_n)_n$  be an enumeration of all rationals with  $w_0 = 0$ .

## II. Results.

**Theorem 1.** A function  $f:R^m \rightarrow R$  is  $d_2$  cliquish iff  $f$  is Lebesgue measurable.

**Definition 1.** A measurable function  $f:R^m \rightarrow R$  is degenerate at a point  $x_0 \in R^m$  iff there exists a neighbourhood  $U$  of  $f(x_0)$  such that the set  $f^{-1}(U)$  has the density zero at  $x_0$ .

A measurable function  $f$  is nondegenerate iff it is not degenerate at any point.

**Theorem 2.** A Lebesgue measurable function  $f:R^m \rightarrow R$  is  $d_2$ -quasi-continuous iff  $f$  is nondegenerate.

**Basic lemma.** Assume that  $A \subset R^m$  is a  $G_\delta$  set of Lebesgue measure zero,  $G \subset R^m$  is an open set and  $A \subset G$ . Then there exists a sequence of pairwise disjoint (L) measurable sets  $A_n \subset G - A$  ( $n = 0, 1, 2, \dots$ ) such that  $\bigcup_{n=0}^{\infty} A_n = G - A$ ,  $\bar{d}(A_n, x) > 0$  for every  $x \in A \cup A_n$  ( $n = 0, 1, 2, \dots$ ) and  $\bar{d}((R^m - G) \cup A_0, x) > 0$  for each  $x \in R^m - G$ .

**Theorem 3.**  $A(Q_{d_2}) = Cq_{d_2}$ .

An outline of proof. It is enough to prove that  $Cq_{d_2} \subset A(Q_{d_2})$ .

Let  $f \in Cq_{d_2}$ . Let  $A$  be a  $G_\delta$  set of measure zero which contains the set of all  $d_2$ -discontinuity points of  $f$ . Let  $A_n$  ( $n=0, 1, 2, \dots$ ) be sets satisfy the conclusion of Basic lemma (for  $G=R^m$ ).

Let us put

$$f_1(x) = \begin{cases} f(x) & \text{for } x \in A \\ w_n & \text{for } x \in A_{2n} \quad ; n=0, 1, 2, \dots \\ f(x) - w_n & \text{for } x \in A_{2n+1} \end{cases}$$

and

$$f_2(x) = \begin{cases} 0 & \text{for } x \in A \\ f(x) - w_n & \text{for } x \in A_{2n}; n=0,1,2,\dots \\ w_n & \text{for } x \in A_{2n+1} \end{cases}$$

The functions  $f_1, f_2$  are  $d_2$ -quasi-continuous and  $f = f_1 + f_2$ .

Theorem 4.  $L(Q_{d_2}) = Cq_{d_2}$

An outline of proof. For  $f \in Cq_{d_2}$  and  $i=0,1,2,3$  let us

put

$$f_i(x) = \begin{cases} w_n & \text{for } x \in \bigcup_{n=0}^{\infty} A_{4n+i} \\ f(x) & \text{for } x \notin \bigcup_{n=0}^{\infty} A_{4n+i} \end{cases}$$

The functions  $f_i$  ( $i = 0,1,2,3$ ) are  $d_2$ -quasi-continuous and

$$f = \min(\max(f_0, f_1), \max(f_2, f_3))$$

Theorem 5.  $B(Q_{d_2}) = Cq_{d_2}$

An outline of proof. It is enough to prove that  $Cq_{d_2} \subset B(Q_{d_2})$ . If  $f \in Cq_{d_2}$  then there exists a Baire 2 function  $g: \mathbb{R}^m \rightarrow \mathbb{R}$  a.e. equal to  $f$ . Let  $h = f - g$  and let  $(G_n)_n$  be a decreasing sequence of open sets such that  $\bigcap_{n=1}^{\infty} G_n = A \supset \{x \in \mathbb{R}^m; h(x) \neq 0\}$  and  $|A| = 0$ . For  $n=1,2,\dots$  let  $(A_{nk})_k$  be a sequence of measurable sets which satisfies the conclusion of Basic lemma (for  $G = G_n$ ). Define

$$h_n(x) = \begin{cases} w_k & \text{for } x \in \bigcup_{n=1}^{\infty} A_{nk} \\ h(x) & \text{for } x \in A \\ 0 & \text{for } x \in (\mathbb{R}^m - G_n) \cup A_{n0} \end{cases}$$

The functions  $h_n$  ( $n=1,2,\dots$ ) are  $d_2$ -quasi-continuous and  $h =$

$\lim_{n \rightarrow \infty} h_n$ . Since  $g$  is Baire 2, there exists a sequence  $(g_n)$  of  $d_2$ -continuous functions with  $g = \lim_{n \rightarrow \infty} g_n$ . The sum

$h_n + g_n$  ( $n = 1,2,\dots$ ) is  $d_2$ -quasi-continuous and  $f = g + h =$   
 $= \lim_{n \rightarrow \infty} (g_n + h_n)$ .

Theorem 6.  $B(Q_{T_e}) \supset Cq_{T_e}$  and  $B(B(Q_{T_e}))$  is the family of all functions with Baire property.

Remark 1. The results which are presented in the theorems 1-5 hold, if instead the basis  $(\mathcal{P}, \implies)$  we will use the basis of disc or squares, or all intervals.

Theorem 7.  $A(Q_{T_e}) = Cq_{T_e}$ .

An outline of proof. Let  $f \in Cq_{T_e}$ . We have  $f = g + h$ , where  $g, h \in Cq_{T_e}$  and for every  $x \in R^m$  there exists a finite limit number  $\alpha_g(x)$  of  $g/C(g)$  and a finite limit number  $\alpha_h(x)$  of  $h/C(h)$ . ( $C(g)$  denotes the set of all continuity points of  $g$ ). Define

$$m_1(x) = \begin{cases} g(x) & \text{if } g \text{ is continuous at } x \\ \alpha_g(x) & \text{if } g \text{ is not continuous at } x \end{cases}$$

$$m_2(x) = \begin{cases} h(x) & \text{if } h \text{ is continuous at } x \\ \alpha_h(x) & \text{if } h \text{ is not continuous at } x \end{cases}$$

$$n_1 = g - m_1 \quad \text{and} \quad n_2 = h - m_2.$$

Since  $m_1$  and  $m_2$  are  $T_e$ -quasi-continuous, it is enough to prove that  $n_1 = f_1 + \Psi_1$  and  $n_2 = f_2 + \Psi_2$ , where  $f_1, f_2, \Psi_1, \Psi_2$  are  $T_e$ -quasi-continuous.

Remark 2. The theorems 1-7 generalize more early results for real functions of one variable.

Let  $R^m = R$ . If  $f: R \rightarrow R$  is a function, then denote by  $Q(f)$  the set of all  $T_e$ -quasi-continuity <sup>points</sup> of  $f$ . Let  $Cq_0$  be the set  $\{f \in Cq_{T_e} : f: R \rightarrow R \text{ and } R - Q(f) \text{ is nowhere dense}\}$ .

Theorem 8. If  $R^m = R$ , we have  $L(Q_{T_e}) = Cq_0$ .

Denote by  $d$  the density topology in  $R$ .

Theorem 9. Every  $d$ -continuous function  $f:R \rightarrow R$  is a sum of two functions  $g, h$  which are  $d$ -continuous and  $T_e$ -quasi-continuous.

Theorem 10. Every derivative  $f:R \rightarrow R$  is a sum of two  $T_e$ -quasi-continuous derivatives.

III. Problems. We have

(1) If each  $x$  section of a function  $f:R^2 \rightarrow R$ ,  $f_x(t) = f(x, t)$  and each  $y$  section  $f^y(t) = f(t, y)$  are  $T_e$ -quasi-continuous, then  $f$  is  $T_e$ -quasi-continuous (Kempisty).

(2) There exists (under Martin Axiom) a function  $f:R^2 \rightarrow R$  that all  $f_x$  and  $f^y$  are  $d$ -quasicontinuous,  $f$  is not  $(d \times d)$ -cliquish and  $f$  is not Lebesgue measurable.

(3) There exists a Lebesgue measurable function  $f:R^2 \rightarrow R$  which is not  $(d \times d)$ -cliquish.

(4) If all  $f_x$  are  $d$ -continuous and if all  $f^y$  are  $d$ -quasi-continuous, then  $f$  is  $(d \times d)$ -cliquish.

(5) There exists a function  $f:R^2 \rightarrow R$  such that all sections  $f_x$  and  $f^y$  are  $d$ -continuous and  $f$  is not  $(d \times d)$ -quasi-continuous.

Problem 1. Is any  $(d \times d)$ -quasi-continuous function  $f:R^2 \rightarrow R$  Lebesgue measurable?

O'Malley defines the following topology in  $R^2$ :

$d_{xy} = \{A \subset R^2; A \text{ is measurable (L) and all sections } A_x, A^y \in d\}$ .  
A function  $f:R^2 \rightarrow R$  is  $d_{xy}$ -cliquish iff it is measurable (L).

Problem 2. What is a characterization of family  $Q_{d_{xy}}$ ?

Problem 3. Denote by  $r$  the O'Malley's topology  $r$  in  $R$ .

What is a characterization of family  $Q_r$ ?
