## RINGS WHOSE MODULES REQUIRE AN INVARIANT NUMBER OF MINIMAL GENERATORS

## William H. Rant

Abstract. We examine rings having the property that, for each minimally generated module, the number of elements in a minimal generator set is invariant.

**Introduction.** Let R be a ring. A left R-module M is a minimally generated module if M contains a subset  $S = \{m_i : i \in I\}$  that generates M, and for each i,  $m_i \notin \text{span}\{m_j : j \neq i\}.$  The set S is a minimal generator set (abbreviated as "mgs") of M. Every left module of a left perfect ring has a minimal generator set. A ring  $R$  has the left invariant minimality property (IMP) and is call an IMP ring if, for each minimally generated left R-module M, the number of elements in each minimal generator set of  $M$  is invariant. The prefix "left" (IMP) is presumed throughout. Unless stated to the contrary, a module is presumed to be a left module. Every module is presumed to be unitary and every ring has an identity. Throughout, " $R$ " denotes a ring and "J" denotes the Jacobson radical of R.

Theorem 1. A ring R has IMP if and only if R is a local ring.

<u>Proof</u>. Assume R is a local ring with  $J = \text{Rad}(R)$ . Let  $S = \{m_i : i \in I\}$  and  $T = \{t_k : k \in K\}$  be minimal generator sets of a minimally generated R-module M. In  $M/JM$  we let  $S^{\wedge} = \{m_i + JM : i \in I\}$  and  $T^{\wedge} = \{t_k + JM : k \in K\}$ . We will show that the canonical map  $p: S \to S^{\wedge}$ , where  $p(m_i) = m_i + JM$ , for all  $i \in I$ , is a bijection. Suppose that  $p(m_k) = p(m_n)$  for some  $k \neq n$ , then  $m_k + JM = m_n + JM$ , so  $m_k = m_n + \sum r_i m_i$  for some  $r_i \in J$ , thus  $(1 - r_k)m_k = \sum_{i \neq k} r_i m_i + m_n$ . Since  $r_k \in J = \text{Rad}(R), r_k$  is a unit.  $m_k = \sum_{i \neq k} (1 - r_k)^{-1} r_i m_i + (1 - r_k)^{-1} m_n$ . This is a contradiction since  $S$  is a minimal generator set of  $M$ . So  $p$  is injective (and clearly surjective). So  $card(S^{\wedge}) = card(S)$ .

Now we show that  $S^{\wedge}$  is a basis for the vector space  $M/JM$  over the division ring  $R/J$ . Clearly  $S^{\wedge}$  generates  $M/JM$ . Suppose that  $S^{\wedge}$  is not a minimal generator set of  $M/JM$ . Then for some  $k, m_k + JM = \sum_{i \neq k} (a_i + J)(m_i + JM)$ , so  $m_k =$  $\sum_{i\neq k} a_i m_i + \sum_i r_i m_i$  for some  $r_i \in J$ . Hence,  $m_k = \sum_{i\neq k} (1 - r_k)^{-1} (a_i + r_i) m_i$ , a contradiction since  $S = \{m_i : i \in I\}$  is a minimal generator set of M. We have shown that  $S^{\wedge}$  is a basis of  $M/JM$  and that  $card(S^{\wedge}) = card(S)$ . In the same manner it can be shown that the mapping  $t_j \rightarrow t_j + RM$  is a bijection from T to  $T^{\wedge}$  (so card $(T^{\wedge}) = \text{card}(T)$ ), and that  $T^{\wedge}$  is a basis of  $M/JM$  over  $R/J$ .

Since any two bases of a vector space have the same cardinality, we know that  $card(S^{\wedge}) = card(T^{\wedge})$ . Thus,  $card(S) = card(T)$ . Hence, the ring R has IMP.

For the converse, assume that R has IMP. To show that R is a local ring we will show that R has only one maximal left ideal. Let  $M_1$  be a maximal left ideal of R. Suppose  $x \in R-M_1$ . We will show that x is a unit. Since  $R = M_1+Rx$ ,  $1 = r+ax$ for some  $r \in M_1$ ,  $a \in R$ ; so  $\{r, x\}$  generates R. Now  $\{1\}$  is a minimal generator set of  $R$  with one element, and since  $R$  has IMP, every mgs of  $R$  must have exactly one element. Thus,  $\{r\}$  or  $\{x\}$  is a mgs of R. Now  $\{r\}$  does not generate R. So  $\{x\}$ is a mgs of R. Hence,  $1 = yx$  for some  $y \in R$ . Suppose  $xy \neq 1$ . Then  $1 - xy = e$ is a non-trivial idempotent and  $R = Re \oplus R(1 - e)$ . Hence,  $\{e, 1 - e\}$  is a minimal generator set of R with two elements, a contradiction. Hence,  $xy = 1$ ; so x is a unit. Therefore,  $R$  has only one maximal left ideal. This proves that  $R$  is a local ring [1].

Definition. Let C be a class of R-modules. A ring R has the invariant minimality property for modules in C if, for each minimally generated  $R$ -module in  $C$ , the number of elements in a minimal generator set is invariant.

## Comments.

- (A) The proof of Theorem 1 shows that the following are equivalent:
	- $(1)$  Ring R has IMP;
	- (2) Ring  $R$  has IMP for the class of cyclic  $R$ -modules;

(3) Ring  $R$  has IMP for the class of free  $R$ -modules;

(4) Every minimal generator set of the module  $_RR$  contains exactly one element.

- (B) Ring R has the left IMP if and only if ring R has the right IMP (since both conditions are equivalent to  $R$  being a local ring).
- (C) The existence of a minimal generator set for each R-module does not imply that the ring R has IMP. Let R be a left perfect ring that is not a local ring. Every left R-module of a left perfect ring has a mgs  $[5]$ , but R doesn't have IMP.

Corollary 1. A ring R has IMP if and only if the ring  $R/J$  has IMP.

<u>Proof</u>. R is a local ring if and only if  $R/J$  is a local ring. The statement follows from Theorem 1.

Corollary 2. Let R be a ring such that each left R-module has a minimal generator set. Then,  $R$  has IMP if and only if  $R$  is a left perfect local ring.

<u>Proof</u>. Assume R has IMP. Then R is a local ring. Let M be a non-zero  $R$ -module. The non-zero, minimally generated module  $M$  contains a maximal submodule [5], thus,  $JM \subseteq Rad(M) \neq M \Rightarrow M \neq JM$ . Hence,  $J = Rad(R)$  is left

T-nilpotent [1]. Since ring  $R/J$  is semisimple (being a division ring) and J is left T-nilpotent,  $R$  is a left perfect ring [1]. Conversely, if we assume that  $R$  is a local ring then  $R$  has IMP by Theorem 1.

Corollary 3. Let  $R$  be a semisimple ring. Then  $R$  has IMP if and only if  $R$  is a division ring.

<u>Proof</u>. Assume R is a semisimple ring with IMP. Since R is a semisimple ring,  $J = \text{Rad}(R) = 0$ . Since R has IMP, R is a local ring; thus,  $R/J = R/\{0\}$  is a division ring. Hence,  $R$  is a division ring.

For the converse, if we assume that  $R$  is a division ring, then  $R$  is a local ring, which implies  $R$  has IMP.

In [4] a ring is defined to be an invariant basis number (IBN) ring if for every free module, the number of elements in a basis is invariant. It is proven as a consequence of [4] that a local ring is an invariant basis number ring. This result follows directly from Theorem 1.

Corollary 4. If  $R$  is a local ring, then  $R$  is an invariant basis number ring.

Proof. If  $R$  is a local ring then  $R$  has IMP by Theorem 1. Since a basis for a free left R-module  $F$  is also a minimal generator set of  $F$ , it follows that any two bases of  $F$  must have the same cardinality. So  $R$  is an IBN-ring.

Definition. Let  $M$  be an  $R$ -module.  $M$  is finitely related if there exist an exact sequence  $0 \to G \to F \to M \to 0$  of finitely generated R-modules F and G, with F free.

Definition. Let M be a minimally generated R-module and let  $S = \{m_i : i \in I\}$ be a mgs of M. Let F be a free R-module with basis  $\{f_i : i \in I\}$ . Consider the epimorphism  $p: F \to M$  defined by  $\sum a_i f_i \to \sum a_i m_i$  and let  $K = \text{ker}(f)$ . If for some mgs  $S$  of  $M$ ,  $K$  is a minimally generated  $R$ -module, then we define  $M$  to be a minimally related A-module.

It is known that every finitely related flat module is projective [4]. Over a local ring this extends to a minimally related flat module.

Theorem 2. Every non-zero, flat, minimally related module of a local ring is a free module.

**Proof.** Let  $M$  be a non-zero, flat, minimally related  $R$ -module of a local ring R. Let  $S = \{m_i : i \in Q\}$  be a mgs of M and let F be a free module with basis  $\{f_i : i \in Q\}$  such that the homomorphism  $f: F \to M$  defined by  $\sum a_i f_i \to \sum a_i m_i$ has a minimally generated kernel K. Let  $x = \sum a_i f_i \in K$ . Since S is a mgs of M, each  $a_i$  is a non-unit, and since R is a local ring, each  $a_i$  must be in  $J = \text{Rad}(R)$ , so

K is contained in JF. Since M is a flat module,  $K \cap JF = JK$ , so  $K = JK$ . Assume that  $K \neq 0$ . Because K is minimally generated, K has a maximal submodule, so  $K \neq \text{Rad}K$ , and thus,  $K \neq JK$ ; a contradiction. Therefore,  $K = 0$ , so  $F \approx M$ , and it follows that  $M$  is a free module.
