# Finiteness of endomorphism algebras of CM modular abelian varieties 

Josep González

#### Abstract

Let $A_{f}$ be the abelian variety attached by Shimura to a normalized newform $f \in S_{2}\left(\Gamma_{1}(N)\right)^{\text {new }}$. We prove that for any integer $n>1$ the set of pairs of endomorphism algebras $\left(\operatorname{End}_{\overline{\mathbb{Q}}}\left(A_{f}\right) \otimes \mathbb{Q}, \operatorname{End}_{\mathbb{Q}}\left(A_{f}\right) \otimes \mathbb{Q}\right)$ obtained from all normalized newforms $f$ with complex multiplication such that $\operatorname{dim} A_{f}=n$ is finite. We determine that this set has exactly 83 pairs for the particular case $n=2$ and show all of them. We also discuss a conjecture related to the finiteness of the set of number fields $\operatorname{End}_{\mathbb{Q}}\left(A_{f}\right) \otimes \mathbb{Q}$ for the non-CM case.

## 1. Introduction

For an abelian variety $A$ defined over a field $\mathbb{L}$, we denote by $\operatorname{End}_{\mathbb{L}}(A)$ the ring of all its endomorphisms defined over $\mathbb{L}$ and $\operatorname{End}_{\mathbb{L}}^{0}(A):=\operatorname{End}_{\mathbb{L}}(A) \otimes \mathbb{Q}$ denotes is endomorphism algebra over $\mathbb{L}$. There is the following conjecture attributed to Robert Coleman.

Conjecture 1.1 Let $n, m \geq 1$ be positive integers. Then, up to isomorphism, there is only finitely many $\mathbb{Q}$-algebras $M$ such that $M \simeq \operatorname{End}_{\mathbb{L}}^{0}(A)$ for some abelian variety $A$ of dimension $n$ defined over a number field $\mathbb{L}$ of degree $m$.

This conjecture is the starting point of this article and, next, we focus our attention on modular abelian varieties. Let us denote by $A_{f} / \mathbb{Q}$ the abelian variety attached by Shimura to a normalized newform $f \in S_{2}\left(\Gamma_{1}(N)\right)^{\text {new }}$ with Fourier expansion $\sum_{n>0} a_{n} q^{n}$, where $q=e^{2 \pi i z}$. It is well-known that $A_{f}$ is a simple quotient over $\mathbb{Q}$ of the jacobian of the modular curve $X_{1}(N)$, whose endomorphism algebra $\operatorname{End}_{\mathbb{Q}}^{0}\left(A_{f}\right)$ is isomorphic to the number field $\mathbb{E}_{f}=$ $\mathbb{Q}\left(\left\{a_{n}\right\}\right)$ and, moreover, $\left[\mathbb{E}_{f}: \mathbb{Q}\right]=\operatorname{dim} A_{f}$. Also, we know that any simple

Keywords: Modular abelian varieties, complex multiplication.
quotient over $\mathbb{Q}$ of $\operatorname{Jac}\left(X_{1}(M)\right)$ is isogenous over $\mathbb{Q}$ to $A_{f}$ for some $f \in$ $S_{2}\left(\Gamma_{1}(N)\right)^{\text {new }}$ with $N \mid M$.

The modular abelian varieties $A_{f}$ can be classified in three types according to their endomorphism algebras over $\overline{\mathbb{Q}}$. Indeed, every $A_{f}$ is isogenous over $\overline{\mathbb{Q}}$ to a power of an absolutely simple abelian variety $B_{f}$. The center of the algebra $\mathcal{A}=\operatorname{End} \frac{0}{\mathbb{Q}}\left(A_{f}\right)$ is either an imaginary quadratic field $\mathbb{K}$ or the totally real number field $\mathbb{F}=\mathbb{Q}\left(\left\{a_{p}^{2} / \varepsilon(p)\right\}_{p \nmid N}\right)$. In the first case, $\mathcal{A}$ is a matrix algebra over $\mathbb{K}, B_{f}$ is an elliptic curve with complex multiplication by $\mathbb{K}$ and it is said that $f$ has CM by $\mathbb{K}$. Otherwise, either $\mathcal{A}$ is a matrix algebra over $\mathbb{F}$, i.e. $B_{f}$ has real multiplication by $\mathbb{F}(R M)$, or $\mathcal{A}$ is a matrix algebra over a quaternion algebra $\mathcal{B}$ with center $\mathbb{F}$, i.e. $B_{f}$ has quaternionic multiplication by $\mathcal{B}(\mathrm{QM})$.

For an integer $n \geq 1$, we consider the set $\mathcal{S}_{n}$ consisting of the pairs of isomorphic classes of $\mathbb{Q}$-algebras $\left(\operatorname{End}_{\overline{\mathbb{Q}}}^{0}\left(A_{f}\right), \operatorname{End}_{\mathbb{Q}}^{0}\left(A_{f}\right)\right)$, where $f$ runs over the set of normalized newforms with $\operatorname{dim} A_{f}=n$. As we show in Section 2, the set of degrees of the smallest number fields where the abelian varieties $A_{f}$ of dimension $n$ have all their endomorphisms defined is bounded. According to Conjecture 1.1, the set $\mathcal{S}_{n}$ should be finite. Of course, we know that for $n=1$ this is true and, more precisely, $\mathcal{S}_{1}$ has exactly 10 pairs: $(\mathbb{Q}, \mathbb{Q})$ and the pairs $(\mathbb{K}, \mathbb{Q})$, where $\mathbb{K}$ is an imaginary quadratic field of class number one.

Since the algebra of endomorphisms defined over $\mathbb{Q}$ of a simple abelian variety over $\mathbb{Q}$ of dimension $n$ is a $\mathbb{Q}$-vector space of dimension at most $n$, the modular abelian varieties $A_{f}$ can be viewed as those with a richer arithmetical structure. Thus, the finiteness of the sets $\mathcal{S}_{n}$ appears as an interesting case to test Coleman's conjecture. This finiteness has been studied for modular abelian varieties with quaternionic multiplication, and partial results can be found in [17] and, for the particular case of surfaces, in [3]. Here, we center our attention on the CM case.

The plan of this paper is as follows. Section 2 is preliminary and devoted to introduce notation and summarize some known facts concerning modular abelian varieties with CM. In Section 3 we prove the modular conjecture for this class of modular abelian varieties and we also determine the set of pairs $\left(\operatorname{End}_{\overline{\mathbb{Q}}}^{0}\left(A_{f}\right), \operatorname{End}_{\mathbb{Q}}^{0}\left(A_{f}\right)\right)$ for the particular case $\operatorname{dim} A_{f}=2$, which turns out to be the most laborious part of this article. In the last section we discuss the non-CM case. For every integer $n>1$, we introduce a value $\widetilde{B}(n) \in \mathbb{N} \cup\{+\infty\}$ which depends on the Fourier coefficients of the normalized newforms $f$ without CM with $\operatorname{dim} A_{f}=n$. We present some evidence that show that $\widetilde{B}(n)$ could be finite and prove that if this is the case, then the set of number fields $\mathbb{E}_{f}$ with $\operatorname{dim} A_{f}=n$ is finite, which implies the finiteness of the set $\mathcal{S}_{n}$ for the RM case. We finish this paper by giving a lower bound for $\widetilde{B}(2)$.

## 2. On modular abelian varieties with CM

Let us denote by $\operatorname{New}_{N}$ the set of normalized newforms of $S_{2}\left(\Gamma_{1}(N)\right)$. For a given $f \in \operatorname{New}_{N}$ with Fourier expansion $\sum_{n>0} a_{n} q^{n}$ and a Dirichlet character $\nu$ of conductor $M$, we denote by $f \otimes \nu$ the only normalized newform with $q$-expansion $\sum_{n>0} b_{n} q^{n}$ that satisfies $b_{n}=\nu(n) a_{n}$ for all integers $n$ with $(n, N M)=1$.

Let $\mathbb{K}$ be an imaginary quadratic field in a fixed algebraic closure $\overline{\mathbb{Q}}$. We denote by $\mathcal{O}$ its ring of integers and by $\chi$ the Dirichlet character attached to $\mathbb{K}$. Let $f=\sum_{n>0} a_{n} q^{n} \in \operatorname{New}_{N}$. By [16], we know that the following three conditions are equivalent:
(i) The newform $f$ has CM by $\mathbb{K}$.
(ii) The newform $f$ satisfies $f=f \otimes \chi$, i.e. $a_{n}=\chi(n) a_{n}$ for all positive integers with $(n, N)=1$.
(iii) There is a primitive Hecke character $\psi: I(\mathfrak{m}) \rightarrow \overline{\mathbb{Q}}^{*}$ of conductor an integral ideal $\mathfrak{m}$ of $\mathbb{K}$ such that

$$
f=\sum_{\mathfrak{a} \in I(\mathfrak{m}), \mathfrak{a} \subset \mathcal{O}} \psi(\mathfrak{a}) q^{\mathrm{N}(\mathfrak{a})},
$$

where $I(\mathfrak{m})$ denotes the multiplicative group of fractional ideals of $\mathbb{K}$ relatively prime to $\mathfrak{m}$ and $N(\mathfrak{a})$ denotes the norm of the ideal $\mathfrak{a}$.

Moreover, for a Hecke character $\psi$ as above, the level $N$ of $f$ is $\mathrm{N}(\mathfrak{m})$ times $D$, where $D$ is the absolute value of the discriminant of $\mathbb{K}$. Attached to $\psi$ we also have:

- The number fields $\mathbb{E}_{f}=\mathbb{Q}\left(\left\{a_{n}\right\}\right)$ and $\mathbb{E}=\mathbb{Q}(\{\psi(\mathfrak{a})\})$. One has

$$
\mathbb{E}=\mathbb{E}_{f} \mathbb{K}
$$

- The character $\eta_{\psi}:(\mathcal{O} / \mathfrak{m})^{*} \rightarrow \overline{\mathbb{Q}}^{*}$ defined by $\eta_{\psi}(a)=\psi((a)) / a$, which is also primitive of conductor $\mathfrak{m}$ and satisfies $\eta_{\psi}(u)=1 / u$ for $u \in \mathcal{O}^{*}$. For every primitive character $\eta$ of conductor $\mathfrak{m}$ satisfying the last condition we have $\eta=\eta_{\psi}$ for some primitive Hecke character $\psi$ of conductor $\mathfrak{m}$. When there is no risk of confusion, we shall write $\eta$ instead of $\eta_{\psi}$.
- The Nebentypus $\varepsilon$ of $f$, which is the Dirichlet character $\bmod N$ defined by $\varepsilon(d)=\chi(d) \eta(d)$.
- The totally real number field $\mathbb{L}_{\varepsilon}=\overline{\mathbb{Q}}^{\text {ker } \varepsilon}$. Here $\varepsilon$ is viewed as a character of the absolute Galois group $\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q})$.

Let us denote by $\Phi$ the set of $\mathbb{K}$-embeddings $\mathbb{E} \hookrightarrow \overline{\mathbb{Q}}$. In [10] the following is proved:
(i) There is a quotient abelian variety $A$ of $A_{f}$ defined over $\mathbb{K}$ equipped with an isomorphism $\iota: \mathbb{E} \xrightarrow{\simeq} \operatorname{End}_{\mathbb{K}}(A) \otimes \mathbb{Q}$ such that $(A, \iota)$ is of CM-type $\Phi$ over $\mathbb{K}$.
(ii) The abelian varieties $A_{f}$ and $A$ are $\mathbb{K}$-isogenous if and only if $\mathbb{K} \nsubseteq \mathbb{E}_{f}$. Otherwise, $A_{f}$ is $\mathbb{K}$-isogenous to $A \times \bar{A}$, where the bar ${ }^{-}$stands for complex conjugation.
(iii) The smallest number field $\mathbb{L}$ where $A$ has all its endomorphisms defined is a cyclic extension of the Hilbert class field $\mathbb{H}$ of $\mathbb{K}$ which is contained in the ray class field of $\mathbb{K} \bmod \mathfrak{m}$ and such that $[\mathbb{L}: \mathbb{H}]=\operatorname{ord} \eta /\left|\mathcal{O}^{*}\right|$. The extension $\mathbb{L} / \mathbb{K}$ is characterized by the property that a prime ideal $\mathfrak{p} \in I(\mathfrak{m})$ splits completely in $\mathbb{L}$ if and only if $\psi(\mathfrak{p}) \in \mathbb{K}$.
(iv) There exists an elliptic curve $E$ defined over $\mathbb{L}$ with CM by $\mathcal{O}$ such that $E^{\operatorname{dim} A}$ and $A$ are isogenous over $\mathbb{L}$.

We say that a number field is the splitting field of an abelian variety if it is the smallest number field where the abelian variety has all its endomorphisms defined. Thus, the number field $\mathbb{L}$ in (iii) is the splitting field of $A$.

Given a Hecke character $\psi$ of conductor $\mathfrak{m}$, the character $\psi_{c}: I(\overline{\mathfrak{m})} \rightarrow \overline{\mathbb{Q}}$ defined by $\psi_{\underline{c}}(\mathfrak{a})=\overline{\psi(\overline{\mathfrak{a}}))}$ is a Hecke character of conductor $\overline{\mathfrak{m}}$ whose attached newform is $\bar{f}$. The condition $\mathbb{K} \nsubseteq \mathbb{E}_{f}$ is equivalent to the equality $\psi_{c}={ }^{\sigma} \psi$ for some $\sigma \in \Phi$ and, in this case, $\mathbb{L}$ is the splitting field of $A_{f}$.

In the next section we will use the following result.
Proposition 2.1 Let $\psi$ be a Hecke character of $\mathbb{K}$ of conductor $\mathfrak{m}$ whose attached newform $f=\sum_{n \geq 0} a_{n} q^{n} \in \operatorname{New}_{N}$ has Nebentypus $\varepsilon$. Assume $\mathbb{K} \nsubseteq \mathbb{E}_{f}$. We have that
(i) The ideal $\mathfrak{m}$ coincides with $\overline{\mathfrak{m}}$.
(ii) The extension $\mathbb{L} / \mathbb{Q}$ is Galois.
(iii) The number field $\mathbb{L}_{\varepsilon}$ is contained in $\mathbb{L}$.
(iv) There exists an elliptic curve $E$ with $C M$ by $\mathcal{O}$ defined over $\mathbb{L}_{0}$ such that $E^{\operatorname{dim} A_{f}}$ and $A_{f}$ are isogenous over $\mathbb{L}_{0}$, where $\mathbb{L}_{0}$ is the maximal real subfield of $\mathbb{L}$.
Moreover, the following conditions are equivalent:
(a) The Nebentypus $\varepsilon$ is trivial, i.e., $f \in S_{2}\left(\Gamma_{0}(N)\right)$.
(b) The number field $\mathbb{E}_{f}$ is totally real.
(c) The Hecke characters $\psi$ and $\psi_{c}$ agree.
(d) For all positive integers $n$ coprime to $N$ we have $\eta(n)=\chi(n)$.

Proof. Part (i) is proved in Lemma 2.1 in [10]. Since $\psi_{c}={ }^{\sigma} \psi$ for $\sigma \in \Phi$, ker $\eta=\operatorname{ker} \eta_{\psi_{c}}$ and, thus, ker $\eta$ is stable under complex conjugation. This fact implies $\mathbb{L}=\overline{\mathbb{L}}$ (cf. Section 3 in [10]) and, therefore, $\mathbb{L} / \mathbb{Q}$ is a Galois extension. Next, we give two proofs for the inclusion $\mathbb{L}_{\varepsilon} \subset \mathbb{L}$, because the arguments involved in both of them will be used in the sequel.

Since $\mathbb{L} / \mathbb{Q}$ is a Galois extension, it suffices to prove that every rational prime $p \nmid N$ which splits completely in $\mathbb{L}$, also splits completely in $\mathbb{L}_{\varepsilon}$. Let $\mathfrak{p}$ and $\overline{\mathfrak{p}}$ be the prime ideals of $\mathbb{K}$ over such a prime $p$. Due to the fact that $\mathfrak{p}$ and $\overline{\mathfrak{p}}$ split completely in $\mathbb{L}$, we have $\psi(\mathfrak{p}), \psi(\overline{\mathfrak{p}}) \in \mathbb{K}$. The condition $\psi_{c}={ }^{\sigma} \psi$ for some $\sigma \in \Phi$ implies $\psi(\overline{\mathfrak{p}})=\overline{\psi(\mathfrak{p})}$ and, thus, $a_{p}=\psi(\mathfrak{p})+\psi(\overline{\mathfrak{p}}) \in \mathbb{Z}$. Since all elliptic curves with CM by $\mathcal{O}$ are ordinary at every prime of good reduction over a rational prime which splits in $\mathbb{K}$ and $A_{f}$ has good reduction at all primes not dividing $N, a_{p} \not \equiv 0(\bmod p)($ see Proposition 5.2 in [2]) and, in particular, $a_{p} \neq 0$. Hence, $\varepsilon(p)=a_{p} / \overline{a_{p}}=1$ and it follows that $p$ splits completely in $\mathbb{L}_{\varepsilon}$.

Now, we present an alternative proof of part (iv). The Weil involution $W_{N}$ of $X_{1}(N)$ is defined over the $N$-th cyclotomic field $\mathbb{Q}\left(\zeta_{N}\right)$ and satisfies ${ }^{\tau_{d}} W_{N}=W_{N}\langle d\rangle$ for all $d \in(\mathbb{Z} / N \mathbb{Z})^{*}$, where $\tau_{d}$ is the element of $\operatorname{Gal}\left(\mathbb{Q}\left(\zeta_{N}\right) / \mathbb{Q}\right)$ mapping $\zeta_{N}$ to $\zeta_{N}^{d}$ and $\langle d\rangle$ denotes the diamond automorphism of $X_{1}(N)$, which is defined over $\mathbb{Q}$. The Weil involution and the diamonds induce automorphisms on $A_{f}$. Since $\langle d\rangle$ acts trivially on $A_{f}$ if and only if $\varepsilon(d)=1, \mathbb{L}_{\varepsilon}$ is the smallest field of definition for $W_{N}$ acting on $A_{f}$ and, thus, $\mathbb{L}_{\varepsilon} \subset \mathbb{L}$.

Let us prove part (iv). We know that $A_{f}$ is isogenous over $\mathbb{L}$ to $E^{\operatorname{dim} A_{f}}$ for some elliptic curve $E$ with CM by $\mathcal{O}$. Since $\mathbb{L}$ is the splitting field of $A_{f}$, we can take $E$ with $j$-invariant $j(\mathcal{O})$ together with an isomorphism $\mu: E \rightarrow \bar{E}$ defined over $\mathbb{L}$. Due to the action of $\mu$ and $\bar{\mu}$ on regular differentials of $E$ and $\bar{E}$, we obtain that $\bar{\mu} \circ \mu=$ id. Therefore, by Weil's descent criterion (cf. [18]) we know that $E$ admits a descent over $\mathbb{L}_{0}$ and, we can assume that $E$ is defined over $\mathbb{L}_{0}$. By Faltings's criterion, to prove the statement it suffices to check, that for every prime $\mathfrak{P}_{0}$ of $\mathbb{L}_{0}$ over a prime $p \nmid N$ with $\mathrm{N}_{\mathbb{L}_{0} / \mathbb{Q}}\left(\mathfrak{P}_{0}\right)=p^{m}$, the reductions of $A_{f}$ and $E^{\operatorname{dim} A_{f}}$ modulo $\mathfrak{P}_{0}$ are isogenous over $\mathbb{F}_{p^{m}}$. When $\mathfrak{P}_{0}$ splits in $\mathbb{L}$, this fact is obvious. Since $p \nmid N, \mathfrak{P}_{0}$ does not ramify in $\mathbb{L}$ so we can assume that $\mathfrak{P}_{0}$ is inert in $\mathbb{L}$. The prime $p$ is also inert in $\mathbb{K}$ because $\mathbb{L}=\mathbb{L}_{0} \mathbb{K}$ and, thus, $m$ is the residue degree of $p \mathcal{O}$ over $\mathbb{L}$. Since $\mathbb{L}_{\varepsilon} \subset \mathbb{L}_{0}, \varepsilon\left(p^{m}\right)=1$ and $a_{p^{2}}^{m}=\psi(p \mathcal{O})^{m}=\eta\left(p^{m}\right) p^{m}=(-1)^{m} p^{m}$. Due to the fact that the residue degree of any prime ideal $\mathfrak{p} \in I(\mathfrak{m})$ in $\mathbb{L}$ is the smallest positive exponent $e$ such that $\psi(\mathfrak{p})^{e} \in \mathbb{K}, m$ is odd. Let us denote by $\mathfrak{P}$ the prime ideal of $\mathbb{L}$ over $\mathfrak{P}_{0}$. By the Eichler-Shimura congruence, the characteristic polynomial of the endomorphism Frob $\mathfrak{F}$ acting on the $l$-adic Tate module of the reduction of $A_{f} / \mathbb{L}$ modulo $\mathfrak{P}$ is $\left(x+p^{m}\right)^{2 \operatorname{dim} A_{f}}$
and, consequently, the characteristic polynomial of the endomorphism Frob $\mathfrak{F}$ corresponding to the reduction of $E / \mathbb{L}$ modulo $\mathfrak{P}$ is $\left(x+p^{m}\right)^{2}$. It follows that the characteristic polynomials of the endomorphism Frob $\mathfrak{P}_{0}$ acting on the $l$-adic Tate modules of the reductions of $A_{f} / \mathbb{L}_{0}$ and $E / \mathbb{L}_{0}$ modulo $\mathfrak{P}_{0}$ are $\left(x^{2}+p^{m}\right)^{\operatorname{dim} A_{f}}$ and $x^{2}+p^{m}$ respectively, which completes the proof of part (iv).

Finally, note that the equivalence between (a) and (b) holds for any newform in $\mathrm{New}_{N}$. Indeed, if $\varepsilon$ is trivial, then it is obvious that $\mathbb{E}_{f}$ is totally real. For the converse, see the proof of Lemma 6.17 of [1]. The remaining equivalences of the statement are immediate.

Remark 2.1 Observe that the splitting field of $A_{f}$ is $\mathbb{L} \mathbb{L}_{\varepsilon}$. Indeed, by part (iii) of the above proposition, it is immediate for $\mathbb{K} \nsubseteq \mathbb{E}_{f}$. When $\mathbb{K} \subseteq \mathbb{E}_{f}$, it follows from the fact that $\mathbb{L}$ is the splitting field of $A$ and $\mathbb{K} \mathbb{L}_{\varepsilon}$ is the smallest field of definition of the induced morphism by the Weil involution $W_{N}$ between $A$ and $\bar{A}$.

Proposition 2.2 Let $n$ be a positive integer. The set of degrees of the splitting fields of all abelian varieties $A_{f}$ of dimension n (with or without CM) is bounded.

Proof. Assume that $\operatorname{dim} A_{f}=n$ and let us denote by $\mathbb{M}$ the splitting field of $A_{f}$. Let $k$ be the greatest integer such that $\varphi(k) \mid 2 n$, where $\varphi$ stands for Euler's function. It is clear that $\left[\mathbb{L}_{\varepsilon}: \mathbb{Q}\right] \leq k$.

First, we consider the CM case. With the above notation, $\mathbb{M}=\mathbb{L} \mathbb{L}_{\varepsilon}$ and, moreover, ord $\eta \leq k$ since $\mathbb{Q}(\eta) \subseteq \mathbb{E}$. Due to the fact that the class number of $\mathbb{K}$ divides $[\mathbb{E}: \mathbb{K}]$ (cf. Theorem 3.1 of $[19])$ and $[\mathbb{E}: \mathbb{K}]$ divides $n$, we obtain

$$
[\mathbb{M}: \mathbb{Q}] \leq[\mathbb{L}: \mathbb{Q}]\left[\mathbb{L}_{\varepsilon}: \mathbb{Q}\right] \leq[\mathbb{H}: \mathbb{Q}] \text { ord } \eta k \leq 2 n k^{2}
$$

For the non-CM case, the number field $\mathbb{M}$ is described in Proposition 2.1 of $[9]$ and it is easy to check that $[\mathbb{M}: \mathbb{Q}] \leq 2^{n} k$.

## 3. Finiteness for the CM case

Let us denote by $\mathrm{New}_{N}^{\mathrm{cm}}$ the subset of $\mathrm{New}_{N}$ consisting of the newforms with CM by an imaginary quadratic field. For every integer $n>0$, let us define $\mathcal{S}_{n}^{\mathrm{cm}}$ as the set of pairs of number fields $(\mathbb{K}, \mathbb{M})$ such that $\mathbb{K}$ is an imaginary quadratic field, $\mathbb{M} \simeq \mathbb{E}_{f}$ for some $f \in \operatorname{New}_{N}^{\mathrm{cm}}$ with CM by $\mathbb{K}$ and $[\mathbb{M}: \mathbb{Q}]=n$. It is clear that the map $\mathcal{S}_{n}^{\mathrm{cm}} \rightarrow \mathcal{S}_{n}$ sending a pair $(\mathbb{K}, \mathbb{M})$ to $\left(\mathrm{M}_{n}(\mathbb{K}), \mathbb{M}\right)$ yields a bijection between $\mathcal{S}_{n}^{\mathrm{cm}}$ and the subset of $\mathcal{S}_{n}$ obtained from newforms with CM.

Theorem 3.1 For any $n>0$, the set $\mathcal{S}_{n}^{\mathrm{cm}}$ is finite.
Proof. Let us prove that the set $\left\{(\mathbb{K}, \mathbb{M} \cdot \mathbb{K}):(\mathbb{K}, \mathbb{M}) \in \mathcal{S}_{n}^{c m}\right\}$ is finite, which is equivalent to the statement. Take $f \in \mathrm{New}_{N}^{\mathrm{cm}}$ attached to a Hecke character $\psi$ of an imaginary quadratic field $\mathbb{K}$ such that $\operatorname{dim} A_{f}=n$. By Theorem 3.1 of [19], the class number $h$ of $\mathbb{K}$ divides $n$ and, moreover, the order $k$ of $\eta$ satisfies that $\varphi(k) \mid 2 n$.

We set $\mathcal{N}=\left\{m \in \mathbb{Z}^{+}: \varphi(m) \mid 2 n\right\}$ and denote by $\mathcal{K}$ the set of imaginary quadratic fields whose class number divides $n$. It is clear that both sets are finite and, consequently, it suffices to prove that, for every pair $(\mathbb{K}, k) \in$ $\mathcal{K} \times \mathcal{N}$, the set of number fields $\mathbb{Q}(\psi)=\mathbb{Q}(\{\psi(\mathfrak{a})\})$ obtained when $\psi$ runs over the set of Hecke characters of $\mathbb{K}$ whose attached character $\eta$ has order $k$ is finite (even without fixing the degree of $\mathbb{Q}(\psi)$ ).

We denote by $\zeta_{m}$ a primitive $m$-th root of unity. Given a pair $(\mathbb{K}, k) \in$ $\mathcal{K} \times \mathcal{N}$, take a Hecke character $\psi$ of $\mathbb{K}$ of conductor $\mathfrak{m}$ for which $\eta$ has order $k$. Let $\left\{\mathfrak{a}_{1}, \ldots, \mathfrak{a}_{h}\right\}$ be a set of representative ideals of the class group of $\mathbb{K}$ and let us denote by $n_{i}, 1 \leq i \leq h$, the order of $\mathfrak{a}_{i}$ in $\operatorname{Gal}(\mathbb{H} / \mathbb{K})$. For every positive integer $i \leq h$, we take $a_{i} \in \overline{\mathbb{Q}}$ such that $a_{i}^{n_{i}} \in \mathbb{K}$ and $a_{i}^{n_{i}} \mathcal{O}=\mathfrak{a}_{i}^{n_{i}}$. Choose $\alpha_{i} \in \mathbb{K}$ such that $\alpha_{i} \mathfrak{a}_{i}$ is relatively prime to $\mathfrak{m}$. Then, $\mathbb{Q}(\psi)=\mathbb{K}\left(\zeta_{k}\right)\left(\psi\left(\alpha_{1} \mathfrak{a}_{1}\right), \ldots, \psi\left(\alpha_{h} \mathfrak{a}_{h}\right)\right)$. Since $\psi\left(\alpha_{i} \mathfrak{a}_{i}\right)^{n_{i}}=a_{i}^{n_{i}} \alpha_{i}^{n_{i}} \eta\left(a_{i} \alpha_{i}\right)^{n_{i}}$, the statement follows from the fact that $\mathbb{Q}(\psi)$ is a subfield of the number field $\mathbb{K}\left(\zeta_{k h}\right)\left(a_{1}, \ldots, a_{h}\right)$.

Next, we focus our attention on the two dimensional case. In order to simplify the notation, we represent an element $(\mathbb{K}, \mathbb{M}) \in \mathcal{S}_{2}^{\mathrm{cm}}$ by the pair $(-d, m)$, where $d$ is the positive square-free integer such that $\mathbb{K}=\mathbb{Q}(\sqrt{-d})$ and $m \neq 1$ is the square-free integer such that $\mathbb{M}=\mathbb{Q}(\sqrt{m})$.

Theorem 3.2 With the above notation, the set $\mathcal{S}_{2}^{\mathrm{cm}}$ has exactly the following 83 pairs:
(i) For the values of $d$ such that $\mathbb{Q}(\sqrt{-d})$ has class number $h=1$ :

$$
\begin{array}{c|c|c|c}
d & 1 & 3 & 2,7,11,19,43,67,163 \\
\hline m & -1, \pm 2, \pm 3 & -1, \pm 3 & -1,-3, \pm d, 3 d
\end{array}
$$

(ii) For the values of $d$ such that $\mathbb{Q}(\sqrt{-d})$ has class number $h=2$ :

| $d$ | $3 \cdot 5,7 \cdot 5,3 \cdot 17,7 \cdot 13,5 \cdot 23,3 \cdot 41,11 \cdot 17,5 \cdot 47,3 \cdot 89,13 \cdot 31,7 \cdot 61$ |
| :---: | :---: |
| $m$ | $\pm p_{1}$ |

where $p_{1}$ is the unique prime dividing d such that $p_{1} \equiv 1(\bmod 4)$, and also

| $d$ | $5,13,37$ | $2 \cdot 3,2 \cdot 11$ | $2 \cdot 5,2 \cdot 29$ |  |
| :---: | :---: | :---: | :---: | :---: |
| $m$ | $-1, d$ | $-1, \pm 2$ | $-1, \pm d / 2$ | . |

Proof. We know that all $f \in \mathrm{New}_{N}^{\mathrm{cm}}$ with $\operatorname{dim} A_{f}=2$ have CM by an imaginary quadratic field whose class number is either 1 or 2 . From now on, $\mathbb{K}$ is an imaginary quadratic field of discriminant $-D$ and class number $h \leq 2$. The square-free part $d$ of $D$ is either $D$ or $D / 4$ depending on whether $D$ is odd or not. Let us denote by $w$ the order of $\mathcal{O}^{*}$, namely $w$ is 2,4 or 6 according to $D>4, D=4$ or $D=3$, respectively.

Firstly, we prove that $(-d,-d) \in \mathcal{S}_{2}^{\mathrm{cm}}$ if and only if $h=1$. Indeed, if $(-d,-d) \in \mathcal{S}_{2}^{\mathrm{cm}}$ then $\mathbb{E}_{f}=\mathbb{K}$ and $[\mathbb{E}: \mathbb{K}]=1$, which implies $h=1$. Conversely, assume $h=1$ and let $\mathfrak{p}$ be a prime ideal over an odd prime $p$ which splits in $\mathbb{K}$, so that $p \equiv 1(\bmod w)$. We can choose $p$ such that $p \equiv 1+w\left(\bmod w^{2}\right)$ and, thus, there exists a character $\eta$ of conductor $\mathfrak{p}$ and order $w$ satisfying $\eta(u)=1 / u$ for all $u \in \mathcal{O}^{*}$. A Hecke character $\psi$ of conductor $\mathfrak{m}=\mathfrak{p}$ and character $\eta$ provides a newform $f$ with $\mathbb{E}=\mathbb{K}$. Since $\mathfrak{m} \neq \overline{\mathfrak{m}}$, part 2 of Proposition 2.1 implies that $\mathbb{K} \subseteq \mathbb{E}_{f}$, and then $\mathbb{E}_{f}=\mathbb{E}=\mathbb{K}$. Therefore, for $h=1$ all pairs $(-d,-d)$ lie in $\mathcal{S}_{2}^{\mathrm{cm}}$.

From now on, we focus our attention on Hecke characters $\psi$ whose number field $\mathbb{E}$ is a biquadratic field $\mathbb{Q}(\sqrt{-d}, \sqrt{m})$ for which $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{m})$. We recall that, in this case, Proposition 2.1 applies and $\mathbb{L}$ is the splitting field of $A_{f}$. We split the proof in two cases according to the class number $h$, and for each of them we examine all possibilities for the values of $\operatorname{ord}(\eta)$.
(1) Case $h=1$. In this case, $\mathbb{E}=\mathbb{K}(\eta)$ and $[\mathbb{K}(\eta): \mathbb{K}]=2$. Therefore, $\varphi(k) / \varphi(w)=2$, where $k$ is the order of $\eta$. So we have the following possibilities for $k, \mathbb{E}$ and $m$ :

|  | $d=1$ |  | $d=3$ | $d \neq 1,3$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $k$ | $8 \quad ; \quad 12$ | 12 | 4 | 6 |  |
| $\mathbb{E}$ | $\mathbb{Q}(\sqrt{-1}, \sqrt{-2}) ; \mathbb{Q}(\sqrt{-1}, \sqrt{-3})$ | $\mathbb{Q}(\sqrt{-1}, \sqrt{-3})$ | $\mathbb{Q}(\sqrt{-d}, \sqrt{-1}) ; \mathbb{Q}(\sqrt{-d}, \sqrt{-3})$ |  |  |
| $m$ | $-2,2 \quad ; \quad-3,3$ | $-1,3$ | $-1, d \quad ;$ | $-3,3 d$ |  |

Next, we prove that all these possibilities for $(-d, m)$ do occur. Let $\mathfrak{l}$ be the prime ideal of $\mathbb{K}$ over the unique rational prime $\ell$ dividing $D$ and consider the integral ideal $\mathfrak{m}_{0}$ defined by

$$
\mathfrak{m}_{0}= \begin{cases}\mathfrak{l} & \text { if } D \neq 3 \text { is odd, } \\ \mathfrak{l}^{2} & \text { if } D=3, \\ \mathfrak{l}^{3} & \text { if } D=4, \\ \mathfrak{l}^{5} & \text { if } D=8\end{cases}
$$

Let $\eta_{0}$ be a character mod $\mathfrak{m}_{0}$ satisfying the following three conditions: the order of $\eta_{0}$ is $w, \eta_{0}(u)=1 / u$ for all $u \in \mathcal{O}^{*}$ and $\eta_{0}(n) \chi(n)$ is the trivial Dirichlet character $\bmod D$. Note that $\eta_{0}$ is unique except for $D=8$.

Let $\psi_{0}$ be the unique Hecke character of conductor $\mathfrak{m}_{0}$ with character $\eta_{0}$. Since $\mathbb{Q}\left(\psi_{0}\right)=\mathbb{K}$ and the newform $f_{0}$ attached to $\psi_{0}$ has trivial Nebentypus, $\operatorname{dim} A_{f_{0}}=1$. By taking Dirichlet characters $\chi_{1}$ of order 4 if $d \neq 1$ and $\chi_{2}$ of order 3 if $d \neq 3$, the newforms $f_{0} \otimes \chi_{1}$ and $f_{0} \otimes \chi_{2}$ have CM by $\mathbb{K}$ and provide the values $m=-1$ and $m=-3$, respectively. This yields $(-d,-1),(-d,-3) \in \mathcal{S}_{2}^{\mathrm{cm}}$ for all $d$ when $h=1$.

For $d \neq 3$, take an inert prime $p$ in $\mathbb{K}$ such that $p \equiv-1(\bmod 3)$. Choose a character $\eta^{\prime} \bmod p \mathcal{O}$ of order 3. The newform obtained from a Hecke character of conductor $\mathfrak{m}=\mathfrak{m}_{0} \cdot p \mathcal{O}$ and character $\eta=\eta_{0} \times \eta^{\prime}$ has trivial Nebentypus. Since $\mathbb{E}=\mathbb{Q}(\sqrt{-d}, \sqrt{-3})$, it follows $(-d, 3 d) \in \mathcal{S}_{2}^{\mathrm{cm}}$.

For $d \neq 1$, take an inert prime $\mathfrak{p}$ in $\mathbb{K}$ such that $p \equiv-1(\bmod 4)$ and choose a character $\eta^{\prime} \bmod p \mathcal{O}$ of order 4. Proceeding as before for the character $\eta_{0} \times \eta^{\prime}$, we obtain $(-d, d) \in \mathcal{S}_{2}^{\mathrm{cm}}$.

For $d=1$, take $p=7$ and the character $\eta^{\prime} \bmod p \mathcal{O}$ of order 8 defined by $\eta^{\prime}(2+i)=(1+i) \sqrt{2} / 2$. For the character $\eta=\overline{\eta_{0}} \times \eta^{\prime}$, we obtain $(-1,2) \in \mathcal{S}_{2}^{\mathrm{cm}}$.

To complete the case $h=1$, we need to prove $(-1,-2) \in \mathcal{S}_{2}^{\mathrm{cm}}$. Take the characters $\eta_{2}$ and $\eta_{3} \bmod 2 \mathcal{O}$ and $3 \mathcal{O}$, respectively, defined by $\eta_{2}(i)=-1$ and $\eta_{3}(1-i)=(1+i) \sqrt{2} / 2$. The newform $f$ obtained from a Hecke character with character $\eta_{2} \times \eta_{3}$ satisfies $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{-2})$.
(2) Case $\boldsymbol{h}=\mathbf{2}$. If $[\mathbb{E}: \mathbb{Q}]=4$, then the order $k$ of $\eta$ can only be 2 , 4 or 6 and, moreover, $k$ must divide $2 D$ (cf. Theorem 3.5 of [19]). Note that, in this particular setting, $\mathbb{E}_{f}$ is a quadratic field if and only if $\psi_{c}={ }^{\sigma} \psi$ for some $\sigma \in \Phi$. Therefore, for all $\alpha \in(\mathcal{O} / \mathfrak{m})^{*}$, we have $\eta(\bar{\alpha})=\overline{\eta(\alpha)}$ if $\varepsilon$ is trivial and, otherwise, $\eta(\bar{\alpha})=\overline{{ }^{\sigma} \eta(\alpha)}=\eta(\alpha)$ for the non-trivial $\sigma \in \operatorname{Gal}(\mathbb{E} / \mathbb{K})$ (for $k=2$, both conditions agree). In particular, if $\mathfrak{m}=\mathfrak{m}_{1} \cdot \mathfrak{m}_{2}$ with $\left(\mathfrak{m}_{1}, \mathfrak{m}_{2}\right)=1$, $\mathfrak{m}_{i}=\overline{\mathfrak{m}}_{i}$ for $i \leq 2$, and $\eta=\eta_{1} \times \eta_{2}$, where $\eta_{i}$ is a character $\bmod \mathfrak{m}_{i}$, then each $\eta_{i}$ has to satisfy the same condition as $\eta$ for all $\alpha \in\left(\mathcal{O} / \mathfrak{m}_{i}\right)^{*}$.

When $h=2, D$ has exactly two prime divisors. Let $\ell$ be such a prime satisfying that the prime ideal of $\mathbb{K}$ over $\ell$ is non-principal. For a given non-principal prime ideal $\mathfrak{p} \in I(\mathfrak{m})$, we have $\mathfrak{p}^{2}=\alpha^{2} \ell \mathcal{O}$ for some $\alpha \in \mathbb{K}^{*}$ and, thus, $\psi(\mathfrak{p})^{2}=\alpha^{2} \ell \eta\left(\alpha^{2} \ell\right)$ and $\sqrt{\ell \eta\left(\alpha^{2} \ell\right)} \in \mathbb{E}$. Therefore, we have to consider the only following possibilities for $k$ and $\mathbb{E}$ :

|  | $D$ | $4 \mid D$ | $3 \mid D$ |
| :---: | :---: | :---: | :---: |
| $k$ | 2 | 4 | 6 |
| $\mathbb{E}$ | $\mathbb{Q}(\sqrt{-d}, \sqrt{\ell}), \mathbb{Q}(\sqrt{-d}, \sqrt{-\ell})$ | $\mathbb{Q}(\sqrt{-d}, \sqrt{-1})$ | $\mathbb{Q}(\sqrt{-d}, \sqrt{-3})$ |

Next, we split the proof according to the value of $k$.
(i) Subcase $k=2$. In this case, $\mathbb{L}=\mathbb{H}$ and, again by Theorem 3.5 of [19], we know that $[\mathbb{E}: \mathbb{K}]=2$ for any Hecke character of $\mathbb{K}$ with $k=2$.

Let $p_{1}$ be the prime that divides $d$ such that the field $\mathbb{K}^{\prime}=\mathbb{Q}\left(\sqrt{p_{1}}\right)$ is the real quadratic subfield of $\mathbb{H}$. Let us now prove that, for $h=2$ and $k=2$, the pair $(-d, m)$ lies in $\mathcal{S}_{2}^{\mathrm{cm}}$ if and only if $D \not \equiv 4(\bmod 8)$ and $|m|=p_{1}$.

Let $\psi$ be a Hecke character such that ord $\eta=2$ and $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{m})$. Since $\mathbb{H}$ is the splitting field of $A_{f}$, there exists an elliptic curve defined over $\mathbb{H}$ with CM by $\mathcal{O}$ which has all the isogenies to its Galois conjugates defined over $\mathbb{H}$. The case $D \equiv 4(\bmod 8)$, i.e. $D=4 \cdot p_{1}$ with $p_{1} \equiv 1$ $(\bmod 4)$, cannot occur because there are no elliptic curves with CM by $\mathcal{O}$ satisfying this property (see 11.3 in [11]). If $D \not \equiv 4(\bmod 8)$, then $d / p_{1}$ is the other prime $p_{2}$ that divides $D$ and, moreover, the number field $\mathbb{E}$ is either $\mathbb{Q}\left(\sqrt{-d}, \sqrt{p_{1}}\right)$ or $\mathbb{Q}\left(\sqrt{-d}, \sqrt{-p_{1}}\right)$, which implies $|m| \in\left\{p_{1}, p_{2}\right\}$. By Proposition 2.1, there exists an elliptic curve $E$ with CM by $\mathcal{O}$ defined over $\mathbb{K}^{\prime}$ such that $A_{f}$ is isogenous over $\mathbb{Q}$ to the Weil restriction Res $_{\mathbb{K}^{\prime}} E$. Since $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{m})$, for the non-trivial $\sigma \in \operatorname{Gal}\left(\mathbb{K}^{\prime} / \mathbb{Q}\right)$ there is $\mu \in \operatorname{Hom}_{\mathbb{K}^{\prime}}\left(E,{ }^{\sigma} E\right) \otimes \mathbb{Q}$ such that $\mu \circ{ }^{\sigma} \mu=[m]$, which implies that $m$ is a norm of $\mathbb{K}^{\prime}$. Due to the fact that neither $p_{2}$ nor $-p_{2}$ are norms of $\mathbb{K}^{\prime}$, it follows that $|m|=p_{1}$.

Next, we prove that, for $D \not \equiv 4(\bmod 8)$, the pairs $\left(d, \pm p_{1}\right) \in \mathcal{S}_{2}^{\mathrm{cm}}$. Let us denote by $\mathfrak{p}_{1}$ and $\mathfrak{p}_{2}$ the ideals over $p_{1}$ and $p_{2}$, respectively. Take the integral ideals

$$
\mathfrak{m}_{0}=\left\{\begin{array}{ll}
\mathfrak{p}_{1} \cdot \mathfrak{p}_{2} & \text { if } p_{1} \text { and } p_{2} \text { are odd, } \\
\mathfrak{p}_{1} \cdot \mathfrak{p}_{2}^{5} & \text { if } p_{2}=2, \\
\mathfrak{p}_{1}^{5} \cdot \mathfrak{p}_{2} & \text { if } p_{1}=2,
\end{array} \quad \text { and } \mathfrak{m}_{1}= \begin{cases}\mathfrak{p}_{2} & \text { if } p_{2} \text { is odd } \\
\mathfrak{p}_{2}^{5} & \text { if } p_{2}=2 .\end{cases}\right.
$$

For a quadratic character $\eta_{0}$ of conductor $\mathfrak{m}_{0}$ such that $\eta_{0}(n)=\chi(n)$ for all integers $n$ coprime to $D$, we obtain a Hecke character $\psi$ whose newform has trivial Nebentypus and, thus, $\mathbb{E}_{f}$ is a real quadratic field. Therefore $m=p_{1}$. For an odd quadratic character $\eta_{1}$ of conductor $\mathfrak{m}_{1}$, we obtain a Hecke character $\psi$ whose newform $f$ has non-trivial Nebentypus and its Fourier coefficient $a_{p_{1}}$ satisfies $a_{p_{1}}^{2}=-p_{1}$. Therefore, $\mathbb{E}=\mathbb{K}\left(\sqrt{-p_{1}}\right)$. It can be easily proved that, for a prime $\mathfrak{p}$ of $\mathbb{K}$, one has $\psi(\mathfrak{p})=\psi_{c}(\mathfrak{p}) \in \mathbb{K}$ when $\mathfrak{p}$ is principal and, otherwise, $\psi(\mathfrak{p})=-\psi_{c}(\mathfrak{p})$ and $\psi(\mathfrak{p}) \sqrt{-p_{1}} \in \mathbb{K}$. Hence, $\psi_{c}={ }^{\sigma} \psi$ for the non-trivial $\sigma \in \operatorname{Gal}(\mathbb{E} / \mathbb{K})$ and, thus, $\mathbb{E}_{f}=\mathbb{Q}\left(\sqrt{-p_{1}}\right)$.
(ii) Subcase $k=4$. For a Hecke character with $k=4$, we know by [19] that $[\mathbb{E}: \mathbb{K}]=2$ if and only if $4 \mid D$ and $\eta\left(2 \alpha^{2}\right)$ has order 4 for some (and every) $\alpha \in \mathbb{K}^{*}$ such that $2 \alpha^{2} \mathcal{O} \in I(\mathfrak{m})$. The last condition amounts to saying that, for any generator $\beta$ of the square of some (and every) non-principal prime ideal $\mathfrak{p} \in I(\mathfrak{m}), \eta(\beta)$ has order 4 . If this is the case, $\mathbb{E}=\mathbb{Q}(\sqrt{-d}, \sqrt{d})$ and we only have to consider the cases $m=-1$ and $m=d$. So we can assume $4 \mid D$ and, in this case, $D$ has a unique odd prime divisor $p_{1}$. We denote by $\mathfrak{p}_{1}$ and $\mathfrak{p}_{2}$ the prime ideals over $p_{1}$ and 2 , respectively.

We first prove that, for $k=4,(-d, d) \in \mathcal{S}_{2}^{\mathrm{cm}}$ if and only if $d$ is odd, i.e., $D \equiv 4(\bmod 8)$.

For $d$ odd, take $\mathfrak{m}=\mathfrak{p}_{1} \cdot \mathfrak{p}_{2}^{3}$ and $\eta=\eta_{1} \times \eta_{2}$, where $\eta_{1}$ is the quadratic character $\bmod \mathfrak{p}_{1}$ and $\eta_{2}$ is a character $\bmod \mathfrak{p}_{2}^{3}$ of order $4\left(\eta_{2}\left(\sqrt{-p_{1}}\right)= \pm i\right)$. For each possible value of $d(d=5,13,37)$, it is easy to find a generator $\beta$ of the square of a non-principal prime ideal $\mathfrak{p}$ and check that its real part is even. So $\eta(\beta)= \pm \eta_{2}(\beta)$ has order 4 because $\eta_{2}\left(\beta^{2}\right)=-1$ and $\mathbb{E}=\mathbb{Q}(\sqrt{-d}, \sqrt{d})$. Since $\varepsilon=1$, we obtain $(-d, d) \in \mathcal{S}_{2}^{\mathrm{cm}}$.

Assume now that $d$ is even and $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{d})$. Since $\mathfrak{m}=\overline{\mathfrak{m}}, \eta$ is primitive of conductor $\mathfrak{m}$ and $\eta(n)=\chi(n)$ for all integers $n$ coprime to the level $N$ of $f$, it must be that:

- The ideal $\mathfrak{m}$ is of the form $\mathfrak{p}_{1} \cdot \mathfrak{p}_{2}^{5} \cdot \prod_{i=1}^{r} p_{i}^{\prime} \mathcal{O}$ for some primes $p_{i}^{\prime}$ with $\left(p_{i}^{\prime}, D\right)=1$,
- The character $\eta$ is of the form $\eta_{1} \times \eta_{2} \times \prod_{i=1}^{r} \eta_{i}^{\prime}$, where $\eta_{1}$ is quadratic $\bmod \mathfrak{p}_{1}, \eta_{2}$ is of order 2 or $4 \bmod \mathfrak{p}_{2}^{5}$, and each $\eta_{i}^{\prime}$ is of order 2 or 4 and primitive of conductor $p_{i}^{\prime} \mathcal{O}$,
- The following conditions have to be satisfied:
(i) $\eta_{1}(n) \cdot \eta_{2}(n)=\chi(n)$ for all integers $n$ coprime to $D$,
(ii) for each $i \leq r, \eta_{i}^{\prime}(n)=1$ for all integers $n$ coprime to $p_{i}^{\prime}$ and $\eta^{\prime}(\bar{\alpha})=\overline{\eta^{\prime}(\alpha)}$ for all $\alpha \in\left(\mathcal{O} / p_{i}^{\prime} \mathcal{O}\right)^{*}$.

If $\mathfrak{m}$ were the ideal $\mathfrak{p}_{1} \times \mathfrak{p}_{2}^{5}$ and $\eta_{2}$ a character of order 4 , then $\eta_{2}(1+$ $\sqrt{-d})^{2}=-1$. In this case, the degree $[\mathbb{E}: \mathbb{Q}]$ would be greater than 4 since for each possible value of $d(d=6,10,22,58)$ it can be found a generator $\beta$ of the square of a non-principal prime ideal $\mathfrak{p} \in I(\mathfrak{m})$ and checked that $\eta_{2}(\beta)^{2}=1$. So $\eta^{\prime}(\beta)$ must necessarily have order 4 , which leads to a contradiction. Indeed, for an inert prime $p_{i}^{\prime}$ in $\mathbb{K}, \mathrm{N}_{\mathbb{K} / \mathbb{Q}}(\beta)=p^{2}$ implies that $\beta$ is a square in the finite field $\mathcal{O} / p_{i}^{\prime} \mathcal{O}$ and, thus, $\eta_{i}^{\prime}(\beta)^{2}=1$. For the split case, the conditions $\mathrm{N}_{\mathbb{K} / \mathbb{Q}}(\beta)=p^{2}$ and $\eta_{i}^{\prime}(\bar{\beta})=\overline{\eta_{i}^{\prime}(\beta)}$ also implies that $\eta_{i}^{\prime}(\beta)^{2}=1$. So $(-d, d) \notin \mathcal{S}_{2}^{\mathrm{cm}}$ for $d$ even.

Let us now prove that, for $k=4,(-d,-1) \in \mathcal{S}_{2}^{\mathrm{cm}}$ for all $d$.
Assume $p_{1} \equiv 1(\bmod 4)$. We take $\mathfrak{m}=\mathfrak{p}_{1}$ and let $\eta$ be a character $\bmod \mathfrak{p}_{1}$ of order 4. It is clear that $\eta(\alpha)=\eta(\bar{\alpha})$ for all $\alpha \in(\mathcal{O} / \mathfrak{m})^{*}$. Moreover, since $p_{1} \not \equiv 1(\bmod 8), \eta(-1)=-1$ and $\eta(2)= \pm i$. Due to the fact that $\eta(2)$ has order 4 , for any Hecke character $\psi$ with attached character $\eta$ we have $\mathbb{E}=\mathbb{Q}(\sqrt{-d}, \sqrt{d})$ and, moreover, $\psi\left(\mathfrak{p}_{2}\right)= \pm(1 \pm i)$. Let $\mathfrak{p}$ be a prime ideal over a prime $p$ which splits in $\mathbb{K}$. By using the fact that $\mathfrak{p}$ is either principal or $\mathfrak{p}=\alpha \mathfrak{p}_{2}$ with $(\alpha) \in I(\mathfrak{m})$, we obtain $a_{p} \in \mathbb{Q}(i)$ and, thus, $\mathbb{E}_{f}=\mathbb{Q}(i)$.

For $p_{1} \not \equiv 1(\bmod 4)$, we take $\mathfrak{m}=\mathfrak{p}_{1} \cdot \mathfrak{p}_{2}^{7}$ and $\eta=\eta_{1} \times \eta_{2}$, where $\eta_{1}$ is a quadratic character mod $\mathfrak{p}_{1}$ and $\eta_{2}$ is an even character of conductor $\mathfrak{p}_{2}^{7}$ and order 4 such that $\eta_{2}(1+\sqrt{-d})=\eta_{2}(5)= \pm i$. It is easy to check that for any Hecke character $\psi$ with character $\eta$ we have ord $\varepsilon=4$ and $\mathbb{E}_{f}=\mathbb{Q}(i)$.
(iii) Subcase $k=6$. By [19], we know that $[\mathbb{E}: \mathbb{K}]=2$ implies $3 \mid D$. Assume $3 \mid D$ and set $p_{1}=3$, so that $p_{2}=d / p_{1}$ is the other prime divisor of $D$. Now, $\mathbb{H}=\mathbb{K}\left(\sqrt{p_{2}}\right)$. Let $\mathfrak{p}_{1}$ and $\mathfrak{p}_{2}$ be the prime ideals over $p_{1}$ and $p_{2}$, respectively.

Although we have already proved that $\left(-d, p_{2}\right) \in \mathcal{S}_{2}^{\mathrm{cm}}$ when $k=2$, we point out that, for $k=6$, this pair is also attained. Let us now prove that $(-d,-3) \notin \mathcal{S}_{2}^{\mathrm{cm}}$. Assume that there exists a Hecke character for which $\eta$ has order 6 and $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{-3})$. The Nebentypus $\varepsilon$ is non-trivial and its order divides 6 . Since the newform $g=f \otimes \varepsilon$ has CM by $\mathbb{K}, \mathbb{E}_{g}=\mathbb{Q}(\sqrt{-3})$ and its Nebentypus is $\varepsilon^{3}$, which must have order 2 . So, we can assume that $\varepsilon$ has order 2. Due to the fact that $\varepsilon \neq 1$, the Weil involution $W_{N}$ acting on $A_{f}$ is non-trivial and, thus, provides an elliptic quotient $E$ of the abelian surface $A_{f}$ defined over the real quadratic field $\mathbb{K}^{\prime}=\mathbb{L}_{\varepsilon}$. The curve $E$ has CM by an order $\mathcal{O}^{\prime}$ of $\mathbb{K}$ and the ring class field of $\mathcal{O}^{\prime}$, which contains $\mathbb{H}$, is $\mathbb{K}^{\prime} \mathbb{K}$. Therefore, $\mathbb{H}=\mathbb{K}^{\prime} \mathbb{K}$ and $\mathbb{K}^{\prime}$ must be $\mathbb{Q}\left({ }^{p}{ }_{2}\right)$. Since $A_{f}$ is isogenous over $\mathbb{Q}$ to $\operatorname{Res}_{\mathbb{K}^{\prime} / \mathbb{Q}} E$ and $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{-} 3),-3$ should be a norm of $\mathbb{K}^{\prime}$ but this condition does not occur when $3 \mid D$.

## 4. On the finiteness for endomorphism algebras over $\mathbb{Q}$

This section is devoted to present evidences about a behavior of the Fourier coefficients of normalized newforms. We show that this conjectural behavior implies the finiteness of the set of number fields $\mathbb{E}_{f}$ with degree $n$ and, thus, the finiteness of the set $\mathcal{S}_{n}$ for the RM case.

For $f \in \operatorname{New}_{N}$, we denote by $S_{2}\left(A_{f}\right)$ the $\mathbb{C}$-vector space generated by the Galois conjugates of $f$, whose dimension is $\operatorname{dim} A_{f}$. We consider the positive integer defined by

$$
B(f):=\max \left\{\operatorname{ord}_{i \infty} h: h \in S_{2}\left(A_{f}\right)\right\} .
$$

In other words, $B(f)$ is the positive integer for which there is a single cuspidal form in $S_{2}\left(A_{f}\right)$ whose $q$-expansion is $q^{B(f)}+\sum_{m>B(f)} a_{m} q^{m}$.

Since $\Omega^{1}\left(A_{f}\right) \simeq S_{2}\left(A_{f}\right) d q / q \subseteq \Omega^{1}\left(X_{1}(N)\right)$, we know that

$$
\operatorname{dim} A_{f} \leq B(f) \leq 2 g_{1}-1
$$

where $g_{1}$ denotes the genus of $X_{1}(N)$. If there exists a curve $C$ defined over $\mathbb{C}$ along with a morphism $\pi: X_{1}(N) \rightarrow C$ such that $S_{2}\left(A_{f}\right) d q / q \subseteq \pi^{*}\left(\Omega^{1}(C)\right)$,
then we can improve the upper bound of $B(f)$ since $B(f) \leq 2 g(C)-1$, where $g(C)$ denotes the genus of $C$. But, we cannot ensure the existence of such a curve with a genus less or equal than a constant depending on $\operatorname{dim} A_{f}$. In fact there is a conjecture about the finiteness of such curves (see Conjecture 1.1 in [1]).

It is natural to ask about the asymptotic behavior of $B(f)$ when $f$ runs over the set of normalized newforms $f$ whose abelian varieties $A_{f}$ have a given dimension.

For every integer $n>0$ and every $x \in \mathbb{R}$ we define

$$
\begin{aligned}
B(n, x) & :=\max \left\{B(f): f \in \operatorname{New}_{N}, \operatorname{dim} A_{f}=n, N \leq x\right\}, \\
B(n) & :=\lim _{x \rightarrow+\infty} B(n, x) .
\end{aligned}
$$

Of course, $B(1)=1$. After computing $B(f)$ for $n=2$ and $N \leq 3000$ with $f$ running over the set of all normalized newforms with trivial Nebentypus, we obtained the results displayed in the following table:

| $B(f)$ | 2 | 3 | 5 | 7 | 11 | 13 | 17 | 19 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\#\left\{A_{f}\right\}$ | 1372 | 1536 | 1155 | 504 | 139 | 43 | 11 | 2 |

Note that if $\operatorname{dim} A_{f}=2$, then $B(f)=k$ if and only if $a_{i} \in \mathbb{Z}$ for all $i<k$ and $a_{k} \notin \mathbb{Z}$, where $f=\sum_{m>0} a_{m} q^{m}$. By the properties of the Fourier coefficients, if the order of the Nebentypus of $f$ is 1 or 2 , then $B(f)$ is a prime.

With regard to the above computational table, one could think that $B(n)<+\infty$ for $n>1$. Nevertheless, this assertion is not right. In fact, $B(n)$ would be $+\infty$ if we only took into account newforms with CM to define $B(n, x)$. Indeed, take for instance $\mathbb{K}=\mathbb{Q}(\sqrt{-7})$ and $n=2$. For any integer $k>7$, let $p_{1}<\cdots<p_{r}$ be the primes $\leq k$ and let $p>k$ be a prime such that $p \equiv-1(\bmod 4)$ and splits in $\mathbb{K}$. Choose a prime $\mathfrak{p}_{i}$ over each $p_{i}$ and a prime $\mathfrak{p}$ over $p$. Let $\mathfrak{m}^{\prime}=\mathfrak{p}_{1}^{2} \cdot \prod_{i=2}^{r} \mathfrak{p}_{i}$. We take $\mathfrak{m}$ to be either $\mathfrak{m}^{\prime}$ or $\mathfrak{m}^{\prime} \cdot \mathfrak{p}$, depending on whether the primitive quadratic character of conductor $\mathfrak{m}^{\prime}$ is odd or not. Let $\eta$ be the primitive quadratic character of conductor $\mathfrak{m}$ and let $\psi$ be the corresponding Hecke character. It is clear that $\mathbb{E}_{f}=\mathbb{Q}(\sqrt{-7})$ and $a_{m}=0$ for all $1<m \leq k$. It follows that $\operatorname{ord}_{i_{\infty}} f-\bar{f}>k$ and, thus, $B(f)>k$.

For newforms without CM, we can use a similar procedure that consists on twisting a newform $f$ by suitable quadratic Dirichlet characters of large conductor to obtain newforms $g$ with $B(g)>k$ and $\operatorname{dim} A_{f}=\operatorname{dim} A_{g}$. For this reason, we shall refine the above definitions to avoid the distortion caused by the effect of twists.

In the sequel $\chi$ stands for a Dirichlet character of any conductor and order. For an integer $n \geq 1$, we say that a normalized newform $f$ without CM
is $n$-primitive if $\operatorname{dim} A_{f}=n$ and $\operatorname{dim} A_{f \otimes \chi} \geq n$ for all Dirichlet characters $\chi$. The reason to exclude the CM case in this definition is the following. For two Hecke characters $\psi$ and $\psi^{\prime}$ of $\mathbb{K}, \psi^{\prime}$ can be viewed as a twist of $\psi$ by a character of $\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{K})$ and it may be that the corresponding newforms $f$ and $f^{\prime}$ satisfy that $\operatorname{dim} A_{f^{\prime}}<\operatorname{dim} A_{f}=n$ and $\operatorname{dim} A_{f \otimes \chi} \geq n$ for all Dirichlet characters $\chi$.

Now, we define

$$
\begin{aligned}
\widetilde{B}(f) & :=\min \left\{B(f \otimes \chi): \operatorname{dim} A_{f \otimes \chi}=\operatorname{dim} A_{f}\right\}, \\
\widetilde{B}(n, x) & :=\max \left\{\widetilde{B}(f): f \in \operatorname{New}_{N} \backslash \operatorname{New}_{N}^{\mathrm{cm}}, N \leq x, f \text { is } n \text {-primitive }\right\}, \\
\widetilde{B}(n) & :=\lim _{x \rightarrow+\infty} \widetilde{B}(n, x) .
\end{aligned}
$$

The range $N \leq 3000$ is too small to detect the effect of twists, but we can see in the above table the quick decrease in the number of abelian surfaces $A_{f}$ when $B(f)$ increases. Now, one suspects that an affirmative answer to the question $\widetilde{B}(n)<+\infty$ should be considered. Next, we show two important consequences about this hypothesis.

Proposition 4.1 Let $n>1$ be an integer. Assume that $\widetilde{B}(m)<+\infty$ for all positive integers $m \leq n$. Then,
(i) The set of number fields $\mathbb{E}_{f}$ of degree $n$ obtained when $f$ runs over the set of all normalized newforms is finite.
(ii) If $n=2$, then $4 \widetilde{B}(2)-1$ is an upper bound for all primes $p \equiv 1$ $(\bmod 4)$ such that the modular curve $X_{0}^{+}(p)=X_{0}(p) /\left\langle w_{p}\right\rangle$ has non cuspidal rational points without CM.

Proof. Let us prove (i). By Theorem 3.1 we can restrict our attention to the non-CM case. First, we assume that $f \in \mathrm{New}_{N} \backslash \mathrm{New}_{N}^{\mathrm{cm}}$ is $n$-primitive. Let $g=f \otimes \chi=\sum_{m>0} a_{m} q^{m}$ be such that $\operatorname{dim} A_{f}=\operatorname{dim} A_{g}$ and $B(g)=$ $\widetilde{B}(f)$. Let us denote by $\tau_{1}, \ldots, \tau_{n}$ the $\mathbb{Q}$-embeddings of $\mathbb{E}_{g}$ into $\overline{\mathbb{Q}}$. The matrix $\left({ }^{\tau_{i}} a_{j}\right)_{i \leq n, j \leq B(g)+1}$ has rank $n$ and, thus, $\left\{a_{1}, \ldots, a_{B(g)+1}\right\}$ is a system of generators of the $\mathbb{Q}$-vector space $\mathbb{E}_{g}$. Under the assumption $\widetilde{B}(n)<+\infty$, we have that $\mathbb{E}_{g}$ is the field $\mathbb{Q}\left(a_{2}, \ldots, a_{\widetilde{B}(n)+1}\right)$. For any integer $m>1, a_{m}$ is an algebraic integer of degree at most $n$ such that $\left|{ }^{\tau_{i}} a_{m}\right| \leq \sigma_{0}(m) \sqrt{m}$ for all $i \leq n$, where $\sigma_{0}(m)=\sum_{0<d \mid m} 1$. Therefore, there are only finitely many possibilities for the values $a_{m}$ and, thus, finitely many possibilities for $\mathbb{E}_{g}$. The condition $\operatorname{dim} A_{g \otimes \chi^{-1}}=n$ implies that the order $k$ of $\chi$ satisfies $\varphi(k) \mid n$. Therefore the number field $\mathbb{E}_{f}$ is a subfield of the compositum of $\mathbb{E}_{g}$ with the $k$-th cyclotomic field, and it follows that the set of number
fields $\mathbb{E}_{f}$ obtained for $n$-primitive newforms $f$ is finite. If $\operatorname{dim} A_{f}=n$ and $f$ is not $n$-primitive, let $\chi$ be a Dirichlet character such that $f_{0}=f \otimes \chi$ is mprimitive for some $m<n$. By using that there are finitely many possibilities for $\mathbb{E}_{f_{0}}$ and for $\mathbb{Q}(\chi)$, it follows that the set of number fields $\mathbb{E}_{f}$ for the case that $\operatorname{dim} A_{f}=n$ and $f$ is not $n$-primitive is also finite.

Let us prove (ii). The existence of a non cuspidal point in $X_{0}^{+}(p)(\mathbb{Q})$ without CM implies the existence of an elliptic curve $E$ without CM defined over a quadratic field $\mathbb{K}$ along with a $p$-isogeny $\mu: E \rightarrow{ }^{\sigma} E$, where $\sigma$ is the non-trivial element of $\operatorname{Gal}(\mathbb{K} / \mathbb{Q})$. If $p \equiv 1(\bmod 4)$, then $p$ is a norm of $\mathbb{K}$ (cf. [8]) and, thus, we can choose $E$ such that $\mu$ is defined over $\mathbb{K}$ and $\mu \circ{ }^{\sigma} \mu=[p]$. Therefore, the Weil restriction $A=\operatorname{Res}_{K / \mathbb{Q}}(E)$ is an abelian surface such that $\operatorname{End}_{\mathbb{Q}}(A) \otimes \mathbb{Q}$ is $\mathbb{Q}(\sqrt{p})$, i.e., $A$ is of $\mathrm{GL}_{2}$-type with real multiplication by $\sqrt{p}$. Due to recent results on Serre's modularity conjecture by Khare-Wintenberger [12], Dieulefait [5] and Kissin [13], the abelian surface $A$ is modular and there exists a normalized newform $f$ with trivial Nebentypus such that $A$ is $\mathbb{Q}$-isogenous to $A_{f}$. It is clear that $f$ is 2-primitive. Let $\chi$ be a quadratic Dirichlet character such that the newform $g=f \otimes \chi=q+\sum_{m>1} a_{m} q^{m}$ satisfies $\widetilde{B}(f)=B(g)$. Due to the fact that $g$ has an inner-twist by the quadratic character attached to $\mathbb{K}$ and its Nebentypus is trivial, the Fourier coefficients of $g$ satisfy the next condition: If $a_{m} \notin \mathbb{Z}$ then $a_{m}^{2} / p \in \mathbb{Z}$. Let $p_{0}$ be the least prime such that $a_{p_{0}} \notin \mathbb{Z}$. Hence, $p_{0} \leq \widetilde{B}(2)$. The statement follows from the inequality $p \leq a_{p_{0}}^{2} \leq$ $\left(2 \sqrt{p_{0}}\right)^{2} \leq 4 \widetilde{B}(2)$.
Remark 4.1 In view of the results in [15], in the QM case we do not see any reason to derive the finiteness of the set $\mathcal{S}_{n}$ from the finiteness of the set of number fields $\mathbb{E}_{f}$ of degree $n$ and, thus, from the condition $\widetilde{B}(n)<+\infty$.

We conclude by giving a better lower bound for $\widetilde{B}(2)$ than the one provided by the above computations for newforms of level $\leq 3000$ and trivial Nebentypus.

Proposition 4.2 There is a 2-primitive normalized newform $f \in S_{2}\left(\Gamma_{0}(2\right.$. $\left.5^{2} \cdot 31159^{2}\right)$ ) such that $\widetilde{B}(f)=B(f)=59$. In particular, $\widetilde{B}(2) \geq 59$.
Proof. Consider the elliptic curve $E: y^{2}=x^{3}+A x+B$, where

$$
\begin{aligned}
& A=13709960(2643250204357-285242082633 \sqrt{-D}) \\
& B=348980800(-18224167668804803284533+63802091292233830777 \sqrt{ } \overline{-D}),
\end{aligned}
$$

and $D=31159$. It can be checked that the conductor of $E$ is the integral ideal of $\mathbb{K}=\mathbb{Q}(\sqrt{-D})$ generated by $2 \cdot 5^{2} \cdot 31159$. The pair $(E, \bar{E})$ provides a non-CM rational point on the curve $X_{0}^{+}(137)$, i.e. $E$ is a quadratic $\mathbb{Q}$-curve without CM of degree 137 (cf. [6]).

We claim that the isogeny $\mu: E \rightarrow \bar{E}$ of degree 137 is defined over $\mathbb{K}$. Indeed, let $x_{1}, \ldots, x_{136}$ be the $x$-coordinates of the non-trivial points of the kernel of $\mu$. By [7], it suffices to prove that $-137 \cdot \mathrm{~N}_{\mathbb{K} / \mathbb{Q}}\left(s_{1}\right) \in\left(\mathbb{K}^{*}\right)^{2}$, where $s_{1}=\sum_{i=1}^{136} x_{i}$. One way to determine $s_{1}$ is to compute the 137 -th division polynomial of $E$, which has degree 9384 , and then to factorize it over $\mathbb{K}$. A better though approximate way is to determine a basis $\left\{\omega_{1}, \omega_{2}\right\}$ of periods of $E$ such that $\tau=\omega_{1} / \omega_{2}$ is in the upper half-plane and satisfies $j(137 \tau)=\overline{j(\tau)}$. Then, $s_{1}=\sum_{i=1}^{136} \wp\left(i / \omega_{2} ; \omega_{1}, \omega_{2}\right)$, where $\wp\left(z ; \omega_{1}, \omega_{2}\right)$ denotes the Weierstrass function attached to the period lattice of $E$. After computing, we obtain

$$
\begin{aligned}
& \omega_{1}=-0.0000059349200452413239 \ldots-0.0000134040043086026752 \ldots i \\
& \omega_{2}=0.0003360230301664207601 \ldots+0.0008081258226439434557 \ldots i \\
& s_{1}=103120(1152883+56273 \sqrt{-D})
\end{aligned}
$$

It is now immediate to check that $-137 \mathrm{~N}_{\mathbb{K} / \mathbb{Q}}\left(s_{1}\right)$ is a square in $\mathbb{K}^{*}$.
Since $\mu$ is defined over $\mathbb{K}$ and $\mu \circ \bar{\mu}=[137]$, the Weil restriction $A=$ $\operatorname{Res}_{\mathbb{K} / \mathbb{Q}}(E)$ satisfies $\operatorname{End}_{\mathbb{Q}}(A) \otimes \mathbb{Q}=\mathbb{Q}(\sqrt{137})$ and, thus, $A / \mathbb{Q}$ is modular. By Milne's formula in [14], the conductor of $A$ is

$$
\mathrm{N}_{\mathbb{K} / \mathbb{Q}}(\operatorname{cond}(E)) \cdot D^{2}=2^{2} \cdot 5^{4} \cdot 31159^{4}
$$

and, thus, there exists a normalized newform $f=\sum_{n>0} a_{n} q^{n} \in S_{2}\left(\Gamma_{0}(N)\right)$ such that $A_{f}$ is $\mathbb{Q}$-isogenous to $A$, where

$$
N=\sqrt{\operatorname{cond}(A)}=2 \cdot 5^{2} \cdot 31159^{2}
$$

(cf. [4]). The newform $f$ has an inner-twist by the quadratic Dirichlet character attached to $\mathbb{K}$. The Fourier coefficients $a_{n}$ lie in $\mathbb{Q}(\sqrt{137})$ and we know that, if $a_{p} \notin \mathbb{Z}$ for a prime $p$, then $A$ has good reduction at $p, p$ is inert in $\mathbb{K}$ and $a_{p} / \sqrt{137} \in \mathbb{Z}$. Then, we have to determine the first inert prime $p_{0}$ such that $a_{p_{0}} \neq 0$. By the Eichler-Shimura congruence, for a prime $p \nmid N$, the polynomial $\left(x^{2}-a_{p} x+p\right)\left(x-{ }^{\sigma} a_{p} x+p\right)$ is the characteristic polynomial of $\mathrm{Frob}_{p}$ acting on the $l$-adic Tate module of the reduction of $A \bmod p$. Therefore, the characteristic polynomial of $\mathrm{Frob}_{p^{2}}$ acting on the on the $l$ adic Tate module of the reduction of $E \bmod p$ is $x^{2}-\left(a_{p}^{2}-2 p\right) x+p^{2}$. After computing, we obtain $p_{0}=59$ and $a_{59}= \pm \sqrt{137}$. Then, the $q$-expansion of $\left(f-{ }^{\sigma} f\right) /(2 \sqrt{137})$ is $\pm q^{59}+O\left(q^{60}\right)$ and, thus, $B(f)=59$.

Let $g=f \otimes \chi=\sum_{n>0} b_{m} q^{m}$, where $\chi$ is any quadratic Dirichlet character. For every inert prime $p<59$ of $\mathbb{K}$ at which $A_{g}$ has god reduction, we know that $A_{f}$ has also good reduction at $p$. Therefore, $b_{p}=\chi(p) a_{p}=0$ and, thus, $\widetilde{B}(f)=B(f)$.
