# **Configurations on elliptic curves**

Andrin Halbeisen, Lorenz Halbeisen and Norbert Hungerbühler

Dedicated to the memory of Branko Grünbaum

An elliptic configuration is a configuration with all its points on a cubic curve, or more precisely, where all points are in the torsion group of an elliptic curve. We investigate the existence of elliptic  $(3r_4, 4r_3)$  configurations for  $r \ge 5$ . In particular, we construct elliptic  $((p-1)_3)$  configurations for every prime p > 7 and show that there are  $(3r_4, 4r_3)$  configurations whenever 3r = p - 1 for some prime p > 7. Furthermore, we show that for every  $k \ge 2$  there is an elliptic  $(9k_4, 12k_3)$  configuration with a rotational symmetry of order 3, where we introduce a new normal form for  $D_3$ -symmetric elliptic curves.

### 1. Terminology

A  $(p_{\lambda}, l_{\pi})$  configuration consists of p points and l lines in the real affine plane such that each point belongs to  $\lambda$  lines and each line goes through  $\pi$  points. If p = l and consequently  $\lambda = \pi$ , we just write  $(p_{\lambda})$  instead of  $(p_{\lambda}, l_{\pi})$ . A configuration is called an *elliptic configuration* if there is a cubic curve which passes through all points of the configuration (see also the discussion of elliptic configurations in [Grünbaum 2009, p. 247 ff.]). Examples of elliptic  $(12_4, 16_3)$  configurations can be found in [Grünbaum 2009, p. 249], [Coxeter 1950, p. 440], and [Feld 1936] (where one can find also an example of an elliptic  $(36_7, 84_3)$  configuration, and for an elliptic  $(24_6, 48_3)$  configuration see [Halbeisen and Hungerbühler 2021]. Metelka [1966] identified 8 elliptic  $(12_4, 16_3)$  configurations.

For a finite group G, a configuration is called G-symmetric if G is a subgroup of the symmetry group of the configuration. There exists an extensive literature on configurations with various types of symmetry (rotational, dihedral, point, chiral, floral): see, e.g., [Berman 2004; 2006]. Finally, an *elliptic G*-symmetric configuration is a configuration which is both elliptic and G-symmetric.

MSC2020: primary 51A20; secondary 51A05.

Keywords: configurations, elliptic curves.

Since a line intersects a cubic curve in at most 3 different points, the maximum value for  $\pi$  of an elliptic  $(p_{\lambda}, l_{\pi})$  configuration is  $\pi = 3$ , and therefore, natural candidates for elliptic configurations are  $(3r_3)$  configurations and  $(3r_4, 4r_3)$  configurations for  $r \ge 1$  (for  $(12_4, 16_3)$  configurations see, for example, [Gropp 1992; Metelka 1985]). Grünbaum [2009, Open Problem 4, p. 293], asked for which  $r \ge 5$  elliptic  $(3r_4, 4r_3)$  configurations exist.

Of particular interest are elliptic configurations with  $C_3$  or  $D_3$  symmetry. Here,  $D_3$  is the dihedral group of the regular triangle, and  $C_3$  its subgroup of elements of odd order. For  $G = D_3$  or  $G = C_3$  the number of lines of a G-symmetric configuration must be a multiple of 3. Hence, since  $3 \mid 4r$  implies  $3 \mid r$ , the possible elliptic  $D_3$  or  $C_3$ -symmetric  $(3r_4, 4r_3)$  configurations are  $(9k_4, 12k_3)$  configurations for  $k \ge 1$ .

After introducing a normal form of cubic curves which are  $D_3$ -symmetric, we give a construction of elliptic  $D_3$ -symmetric  $(9k_4, 12k_3)$  configurations for every  $k \ge 2$ . Finally, we show the existence of elliptic  $(3r_4, 4r_3)$  configurations for some  $r \ge 5$ . The constructions of elliptic configurations are motivated by Schroeter's ruler construction of cubic curves (see [Halbeisen and Hungerbühler 2021]).

#### 2. A $D_3$ -symmetric normal form for cubic curves

In this section, we will introduce a normal form of cubic curves which are  $D_3$ -symmetric and show that every nonsingular cubic curve can be transformed into this form by a projective transformation. This normal form of cubic curves will be used later in order to construct elliptic  $D_3$ -symmetric configurations.

It is well known that every nonsingular cubic curve in the real projective plane can be transformed into Weierstrass normal form:

$$y^2 = x^3 + ax^2 + bx.$$

Without loss of generality, we may require that the x-coordinate of an inflection point is 1. In this case we get (see [Halbeisen and Hungerbühler 2019, Fact 2.3])

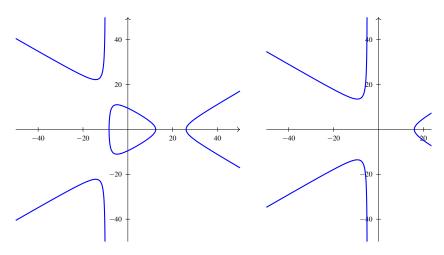

$$b \neq 1$$
 and  $a = \frac{b^2 - 6b - 3}{4}$ . (1)

Now, by computing the polar conic at the point (0, 1, 0) in the projective extension of the plane as well as the intersection points of the tangents at the inflections points, we find the projective transformation

$$\begin{pmatrix} 1 & 0 & -2b \\ 0 & \sqrt{3}(b-1)/2 & 0 \\ 1 & 0 & b-3 \end{pmatrix}$$

which transforms the affine curve  $y^2 = x^3 + ax^2 + bx$  (with a, b as in (1)) into the curve

$$\Gamma_{D_3}: x^3 - 3xy^2 - 3(b-3)(x^2 + y^2) + 4b^2(b-9) = 0.$$

**Figure 1.** Elliptic  $D_3$ -symmetric curves for b = 13 (left), and b = 8 (right).

To see that the latter curve is  $D_3$ -symmetric, notice first that the curve is symmetric with respect to the x-axis. To see that the curve is also symmetric with respect to rotations about the origin with angle  $\frac{2\pi}{3}$ , notice that if  $(x_0, y_0)$  is a point on the curve  $\Gamma_{D_3}$ , then also

$$\begin{pmatrix} \cos\frac{2\pi}{3} & \sin\frac{2\pi}{3} \\ -\sin\frac{2\pi}{3} & \cos\frac{2\pi}{3} \end{pmatrix} \begin{pmatrix} x_0 \\ y_0 \end{pmatrix}$$

is a point on  $\Gamma_{D_3}$ . Figure 1 shows two  $D_3$ -symmetric curves  $\Gamma_{D_3}$ .

Conic sections have a natural reflection symmetry along their axes. It is quite natural to look at cubic curves in a  $D_3$ -symmetric form. In this regard, we now have:

**Proposition 1.** Every regular cubic curve can be brought, by a projective transformation, into the  $D_3$ -symmetric normal form

$$\Gamma_{D_3}$$
:  $x^3 - 3xy^2 - 3(b-3)(x^2 + y^2) + 4b^2(b-9) = 0$ 

with  $b \in \mathbb{R} \setminus \{1\}$ .

**Remarks.** Since the 3 points at infinity of an elliptic  $D_3$ -symmetric curve are the 3 inflection points of the curve, the projective transformation which transforms a curve in Weierstrass normal form into our  $D_3$ -symmetric normal form is in general not rational (e.g., in the case when the parameter b is rational).

Concerning the arithmetic on elliptic  $D_3$ -symmetric curves it turns out that the formulae to add or to double points are somewhat more involved than the corresponding formulae for curves in Weierstrass normal form.

#### 3. Elliptic $D_3$ -symmetric $(9k_4, 12k_3)$ configurations

In order to construct an elliptic  $D_3$ -symmetric  $(9k_4, 12k_3)$  configuration for some  $k \ge 2$ , we take an arbitrary  $D_3$ -symmetric elliptic curve  $\Gamma_0$  with neutral element  $\mathscr{O} = (0, 1, 0)$  and choose a point Q on  $\Gamma_0$  of order 9k + 3. This can be achieved by considering a p-periodic parametrization of the curve by the Weierstrass  $\wp$ -function and taking the point Q as the image of the parameter value  $\frac{pq}{9k+3}$  for some q with  $\gcd(q, 9k+3) = 1$ . See [Silverman 2009, Chapter VI, §3] for details. As a matter of fact, we would like to mention that the points which are constructed in this way are in general irrational. Mazur's classification theorem [1977; 1978] limits the possibility for elliptic configurations with rational points; see Figure 8 for an example of a configuration which cannot have only rational points.

Notice that  $k \ge 2$  is necessary, since k = 1 corresponds to the Hesse configuration  $(9_4, 12_3)$  which can be realized in the complex projective plane as the set of inflection points of an elliptic curve, but which has no realization with straight lines in the Euclidean plane because of the Sylvester–Gallai theorem. In fact, our construction, which we present below, works only for  $k \ge 2$ .

The group  $G_k$  on  $\Gamma_0$ , generated by the point Q, is isomorphic to the group  $\mathbb{Z}/(9k+3)\mathbb{Z}$ . For  $1 \le i \le 9k+3$ , let

$$P_i := i * Q := \underbrace{Q + Q + \cdots + Q}_{i \text{ terms}},$$

where we denote the group operation on  $\Gamma_0$  by +. We define the following three sets of points:

$$S_0 := \{P_1, \ldots, P_{3k}\}, \qquad S_1 := \{P_{3k+2}, \ldots, P_{6k+1}\}, \qquad S_2 := \{P_{6k+3}, \ldots, P_{9k+2}\}.$$

Then each  $S_j$  (for  $j \in \{0, 1, 2\}$ ) contains 3k pairwise distinct points, and since the sets  $S_j$  are pairwise disjoint, the set  $S := S_0 \cup S_1 \cup S_2$  contains 9k pairwise distinct points on the curve  $\Gamma_0$ . Notice that since the points  $P_{3k+1}$ ,  $P_{6k+2}$  of order three, and  $P_{9k+3}$  are the only points of  $\Gamma_0$  at infinity and none of them belongs to S, all points of S belong to the real affine plane. The goal is now to construct a  $D_3$ -symmetric,  $(9k_4, 12k_3)$  configuration on the set of points S. Before we start with the construction, let us introduce some notation.

- We identify the group  $G_k$  with the group  $\mathbb{Z}/(9k+3)\mathbb{Z}$ , and for  $1 \le u \le 9k+3$ , we identify the point  $P_u$  with  $u \in G_k$  (i.e., with an element in  $\mathbb{Z}/(9k+3)\mathbb{Z}$ ). Similarly, we identify S with a subset of  $G_k$ .
- If 3 distinct points  $P_u$ ,  $P_v$ ,  $P_w$  are collinear (i.e., lie on a line), then the line is denoted by [u, v, w]. Notice that by the group law of an elliptic curve, we have that 3 distinct points  $P_u$ ,  $P_v$ ,  $P_w$  are collinear if and only if  $u + v + w \equiv 0 \pmod{9k+3}$ . In other words, each line through 3 different points is of the form [u, v, w] for some pairwise distinct  $u, v, w \in G_k$ .

- If [u, v, w] is a line, then -[u, v, w] := [-u, -v, -w] is the *inverse line* of [u, v, w]. Notice that if [u, v, w] is a line in S (i.e.,  $u, v, w \in S$ ), then -[u, v, w] is a line in S with  $-[u, v, w] \neq [u, v, w]$ , namely the line mirrored at the x-axis.
- For  $u \in G_k$ , we define  $\rho(u) := u + (3k + 1)$ . Notice that if, for example,  $u \in S_0$ , then  $\rho(u) \in S_1$  and  $\rho^2(u) := (\rho \circ \rho)(u) \in S_2$ .
- If [u, v, w] is a line, then  $\rho[u, v, w] := [\rho(u), \rho(v), \rho(w)]$  is the corresponding *rotated line*. Notice that if [u, v, w] is a line in S, then  $\rho[u, v, w]$  and  $\rho^2[u, v, w]$  are lines in S, where [u, v, w],  $\rho[u, v, w]$ , and  $\rho^2[u, v, w]$  are pairwise distinct (but not necessarily disjoint) lines.

The following fact is an immediate consequence of the preceding definitions.

Fact 2. Any  $(9k_4, 12k_3)$  configuration on the point set S, which contains with any line [u, v, w] also the lines  $\rho[u, v, w]$  and  $\rho^2[u, v, w]$ , is an elliptic  $C_3$ -symmetric  $(9k_4, 12k_3)$  configuration, where  $C_3$  is the cyclic group of order 3. If the configuration contains in addition with any line [u, v, w] also the line -[u, v, w], then it is an elliptic  $D_3$ -symmetric configuration.

So, by Fact 2, to construct an elliptic  $D_3$ -symmetric  $(9k_4, 12k_3)$  configuration it suffices to find 2k lines  $[u_i, v_i, w_i]$  such that for  $1 \le i \le 2k$ , the lines  $\pm [u_i, v_i, w_i]$ ,  $\pm \rho[u_i, v_i, w_i]$ , and  $\pm \rho^2[u_i, v_i, w_i]$  are pairwise distinct. Before we start constructing such lines, we show how we construct lines in S from "proto-lines" in  $S_0$ :

For any  $u, v, w \in S$ , let

```
u_0 := u \pmod{3k+1}, \quad v_0 := v \pmod{3k+1}, \quad w_0 := w \pmod{3k+1}.
```

Then  $u_0, v_0, w_0 \in S_0$  and if [u, v, w] is a line, then  $u_0 + v_0 + w_0 \equiv 0 \pmod{3k+1}$ . If, on the other hand,  $u, v, w \in S_0$  are such that  $u + v + w \equiv 0 \pmod{3k+1}$ , then the triple (u, v, w) is called a *proto-line* in  $S_0$ . Notice that we do not require that the 3 points u, v, w of a proto-line (u, v, w) are pairwise distinct.

The following lemma will be crucial in the construction of  $(9k_4, 12k_3)$  configurations.

**Reduction lemma 3.** If  $u, v, w \in S_0$  are such that (u, v, w) is a proto-line, then there are  $\bar{u}, \bar{v}, \bar{w} \in S$  such that  $u = \bar{u}', v = \bar{v}', w = \bar{w}'$  and  $[\bar{u}, \bar{v}, \bar{w}]$  is a line.

*Proof.* Let  $u, v, w \in S_0$  be such that (u, v, w) is a proto-line. Notice that since  $u + v + w \equiv 0 \pmod{3k+1}$  and  $3 \nmid 3k+1$ , at most 2 of the 3 points u, v, w can be equal. Without loss of generality assume  $u \neq v$ . Then, for  $\bar{u} := u$ ,  $\bar{v} := v$ , and  $\bar{w} := w + (6k+2)$ ,  $[\bar{u}, \bar{v}, \bar{w}]$  is a line.

In order to construct an elliptic  $C_3$ -symmetric  $(9k_4, 12k_3)$  configuration, by Reduction lemma 3 and by rotating the lines with  $\rho$  and  $\rho^2$ , respectively, it suffices

to find a set L of 4k proto-lines in  $S_0$  such that each point of  $S_0$  belongs to exactly 4 proto-lines in L. In order to construct an elliptic  $D_3$ -symmetric  $(9k_4, 12k_3)$  configuration, we have to make sure that for each proto-line (u, v, w) in L, (-u, -v, -w) is also in L.

**Theorem 4.** For every integer  $k \ge 2$  there exists an elliptic  $D_3$ -symmetric  $(9k_4, 12k_3)$  configuration.

The proof of this theorem will be carried out in the following sections by explicit constructions of the corresponding configurations. In particular, we will construct elliptic  $(9k_4, 12k_3)$  configurations for  $k \equiv 3 \pmod{4}$ , for  $k \equiv 1 \pmod{4}$ , and for k even, respectively.

**3.1.**  $D_3$ -symmetric (9 $k_4$ , 12 $k_3$ ) configurations for  $k \equiv 3 \pmod 4$ ). Let  $k \ge 3$  be a positive integer with  $k \equiv 3 \pmod 4$ , and let  $n_k := 3k+1$ . The first step in the construction of a (9 $k_4$ , 12 $k_3$ ) configuration is the construction of 4k proto-lines. For this, we start with a triple ( $a_0$ ,  $b_0$ ,  $c_0$ ) with  $a_0 + b_0 + c_0 \equiv 0 \pmod {n_k}$ , where  $a_0$ ,  $b_0$ ,  $c_0$  are not necessarily nonzero. Then, we build successively the  $n_k$  triples ( $a_{i+1}$ ,  $b_{i+1}$ ,  $c_{i+1}$ ) := ( $a_i - 2$ ,  $b_i + 1$ ,  $c_i + 1$ ) in  $\mathbb{Z}/n_k\mathbb{Z}$ . Among these triples, there will be 2 triples which are not proto-lines because one of the numbers is 0. We then replace these 2 triples by 2 proto-lines and construct additional k-1 proto-lines in order to obtain 4k proto-lines.

We construct the 4k proto-lines as follows: let

$$m_1 := \frac{k+1}{2}, \qquad m_2 := n_k - m_1,$$

and let

$$t_1 := \begin{cases} \frac{m_1}{2} & \text{if } m_1 \equiv 2 \pmod{4}, \\ \frac{n_k + m_1}{2} & \text{otherwise,} \end{cases}$$
  $t_2 := n_k - t_1.$ 

Since  $k \equiv 3 \pmod 4$ , we have that  $k+1 \equiv 0 \pmod 4$  and therefore,  $n_k$ ,  $m_1$  and  $m_2$  are even. Moreover, since  $m_1 \equiv 0$  or  $2 \pmod 4$ , and since  $n_k \equiv 2 \pmod 4$ , we have either  $m_1 \equiv 2 \pmod 4$  or  $n_k + m_1 \equiv 2 \pmod 4$ , which implies that  $t_1$  and  $t_2$  are both odd, in fact  $t_1$ ,  $t_2 \equiv 1 \pmod 4$ .

Let  $S_0^* := S_0 \cup \{0\}$  and define a sequence of triples  $\langle (a_i, b_i, c_i) : 0 \le i < n_k \rangle$  in  $S_0^* \times S_0^* \times S_0^*$  as follows: Let

$$(a_0, b_0, c_0) := (t_1, 0, t_2)$$

and for  $0 \le i < n_k$  let

$$(a_i, b_i, c_i) := (t_1 - 2i, i, t_2 + i) \pmod{n_k}.$$

Then, the sequence has the following properties:

- (a) For all  $0 \le i < n_k$ ,  $a_i + b_i + c_i \equiv 0 \pmod{n_k}$  and  $a_i$  is odd. For the latter, recall that  $t_1$  is odd and that  $n_k$  is even.
- (b)  $(a_{t_1}, b_{t_1}, c_{t_1}) = (t_2, t_1, 0) \pmod{n_k}$ , e.g.,  $a_{t_1} = t_1 2t_1 = -t_1 \equiv t_2 \pmod{n_k}$ .
- (c) For all  $0 \le i < j < n_k$  we have  $\{a_i, b_i, c_i\} \ne \{a_j, b_j, c_j\}$ .
- (d) For all  $0 \le i < n_k$  we have

$$-(a_i, b_i, c_i) = -(t_1 - 2i, i, t_2 + i) = (t_2 + 2i, -i, t_1 - i) = (a_{t_1 - i}, c_{t_1 - i}, b_{t_1 - i}).$$

Property (a) shows that every triple in the sequence is a proto-line in  $S_0^*$ . Property (c) shows that the sequence contains exactly  $n_k$  pairwise different proto-lines; let  $L^*$  be the set of these  $n_k$  proto-lines. Property (d) shows that a proto-line (u, v, w) is in  $L^*$  if and only if the proto-line -(u, v, w) is in  $L^*$ .

Every even number  $0 \le \ell < n_k$  appears in exactly 2 proto-lines in  $L^*$ , and every odd number  $0 < \ell < n_k$  appears in exactly 4 proto-lines in  $L^*$ . Now, we remove the 2 proto-lines  $(t_1, 0, t_2)$  and  $(t_2, t_1, 0)$  from  $L^*$ , and introduce the 2 proto-lines  $(m_1, t_2, t_2)$  and  $(m_2, t_1, t_1)$  to  $L^*$ ; the resulting set of proto-lines is denoted  $L_0$ . Notice that  $(m_2, t_1, t_1) = -(m_1, t_2, t_2)$ , that the 2 proto-lines  $(m_1, t_2, t_2)$  and  $(m_2, t_1, t_1)$  are not in  $L^*$ , and that every proto-line in  $L_0$  is a proto-line in  $S_0$ . In  $L_0$ , every odd number  $0 < \ell < n_k$  appears in exactly 4 proto-lines in  $L_0$ , and every even number  $0 < \ell < n_k$ , except  $m_1$  and  $m_2$ , appears in exactly 2 proto-lines in  $L_0$ , whereas  $m_1$  and  $m_2$  appear in exactly 3 proto-lines in  $L_0$ .

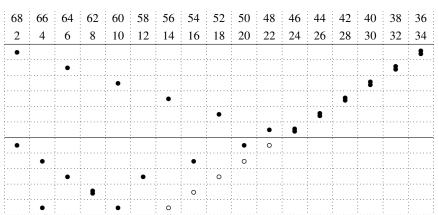

**Example 1.** For k = 3 (i.e.,  $n_k = 10$ ), we start with the triple (1, 0, 9) and get successively the triples (9, 1, 0), (7, 2, 1), (5, 3, 2), (3, 4, 3), (1, 5, 4), (9, 6, 5), (7, 7, 6), (5, 8, 7), (3, 9, 8). We now replace the 2 triples (1, 0, 9) and (9, 1, 0) by the 2 proto-lines (2, 9, 9) and (8, 1, 1). This way, each odd number appears in a proto-line exactly 4 times, and each even number, except 2 and 8, appears in a proto-line exactly twice, whereas 2 and 8 appear 3 times. The additional k - 1 = 2 proto-lines will then be (2, 4, 4) and (8, 6, 6).

In order to complete the construction of a  $(9k_4, 12k_3)$  configuration, we consider the set  $T_k$  consisting of the  $n_k/2-1$  even numbers  $2, 4, \ldots, n_k-2$ . It remains to find k-1 proto-lines in  $S_0$  with points in  $T_k$ , where every number in  $T_k$  except  $m_1$  and  $m_2$  appears in exactly 2 proto-lines, whereas  $m_1$  and  $m_2$  appear in exactly 1 proto-line. Together with the  $n_k=3k+1$  proto-lines of  $L_0$ , this gives us 4k proto-lines, and after extending them to lines of S by Reduction lemma 3 and by rotating them with  $\rho$  and  $\rho^2$ , we finally obtain 12k lines. For the remaining k-1 proto-lines with points in  $T_k$ , by trial and error we have found the following pattern, which is obtained in the following way: First, we write the points of  $T_k$  in two rows, where the first row contains the numbers  $n_k-2$  to  $(n_k-2)/2+1$  in reverse order, and the second row contains the numbers 2 to  $(n_k-2)/2$  in the natural order.

Below the numbers of these two rows, we write  $\bullet$  and  $\circ$  for the 3 points of the proto-lines, where  $\bullet$  denotes a number from the second row, and  $\circ$  denotes a number from the first row. Finally,  $\bullet$  means the same number is listed twice. The following diagram gives an example of 3 proto-lines for k=7 (i.e.,  $n_k=22$ ), according to the construction described above:

20	18	16	14	12
2	4	6	8	10
•		•	0	
0		0	•	
:			0	

The first proto-line is (2, 6, 14), the second is (20, 16, 8) = -(2, 6, 14), and the third is (4, 4, 14). Notice that -(u, v, w) is obtained from (u, v, w) by exchanging  $\bullet$  and  $\circ$ . Now, instead of writing both proto-lines (u, v, w) and -(u, v, w), we just write the one which uses the greater number of  $\bullet$ 's—having in mind that each proto-line (u, v, w) represents also the proto-line -(u, v, w). This way, we just have to find  $\frac{k-1}{2}$  proto-lines. The following diagram illustrates the 11 proto-lines for k = 23 (i.e.,  $n_k = 70$ ), given in two parts:

First, notice that the proto-lines given in the diagram contain only even numbers and are therefore different from the proto-lines in  $L_0$ . Furthermore, we see that each point, except the points 12 and 58, appears in exactly 2 proto-lines, whereas the points 12 and 58 appear in exactly 1 proto-line. Notice that for k = 23,  $m_1 = \frac{k+1}{2} = 12$  and  $m_2 = n_k - m_1 = 58$ .

Now, we give a more formal construction of the remaining  $\frac{k-1}{2}$  proto-lines: Let  $\tilde{n}_k := n_k/2$ . The  $\frac{k+1}{4}$  proto-lines in the first part are

$$(2+4i, (\tilde{n}_k-1)-2i, (\tilde{n}_k-1)-2i)$$
 where  $0 \le i \le \frac{k-3}{4}$ .

In particular, for i = 0 we obtain  $(2, \tilde{n}_k - 1, \tilde{n}_k - 1)$ , and for  $i = \frac{k-3}{4}$  we obtain (k-1, k+1, k+1) (notice that  $2 + 4 \cdot \frac{k-3}{4} = k - 1$  and  $\left(\frac{3k+1}{2} - 1\right) - 2 \cdot \frac{k-3}{4} = k + 1$ ).

Furthermore, the  $\frac{k-3}{4}$  proto-lines in the second part are

$$(2+2i, (k-3)-4i, -(k-1)+2i)$$
 where  $0 \le i \le \frac{k-7}{4}$ .

In particular, for i = 0 we obtain (2, k - 3, -(k - 1)), and for  $i = \frac{k-7}{4}$  we obtain  $\left(\frac{k-3}{2}, 4, -\frac{k+5}{2}\right)$ . Notice  $2 + 2 \cdot \frac{k-7}{4} = \frac{k-3}{2}$ ,  $(k-3) - 4 \cdot \frac{k-7}{4} = 4$ , and  $-(k-1) + 2 \cdot \frac{k-7}{4} = -\frac{k+5}{2}$ . Now, since  $\frac{k-3}{2} + 2 = m_1$  and  $-\left(\frac{k+5}{2} - 2\right) = m_2$ , we see that the only numbers which appear in exactly 1 proto-line are  $m_1$  and  $m_2$ .

**Example 2.** We illustrate the construction described above for the parameter k = 3. This leads to an elliptic  $D_3$ -symmetric (27<sub>4</sub>, 36<sub>3</sub>) configuration. The underlying group is  $\mathbb{Z}_{30}$  on  $\Gamma_0$ . We obtain:

- k = 3,  $n_k = 10$ ,  $m_1 = 2$ ,  $m_2 = 8$ ,  $t_1 = 1$ ,  $t_2 = 9$ .
- The proto-lines in  $L^*$  given in Example 1 are

$$(1,0,9), (9,1,0), (7,2,1), (5,3,2), (3,4,3),$$
  
 $(1,5,4), (9,6,5), (7,7,6), 5, 8, 7), (3,9,8).$ 

- Remove (1, 0, 9) and (9, 1, 0), and introduce (2, 9, 9) and (8, 1, 1). This gives us the 10 proto-lines of *L*<sub>0</sub>.
- The diagram, which yields the additional  $\frac{k-1}{2} = 1$  line consists just of a single line:

This gives us the lines (2, 4, 4) and (8, 6, 6).

• Together with the 10 proto-lines in  $L_0$ , we have now 12 proto-lines which we extend to proper lines in S and rotate them.

Observe that depending on how we extend the proto-lines to proper lines, and depending on the choice of the generator of  $\mathbb{Z}_{30}$ , we obtain different resulting configurations. One version is shown in Figure 2.

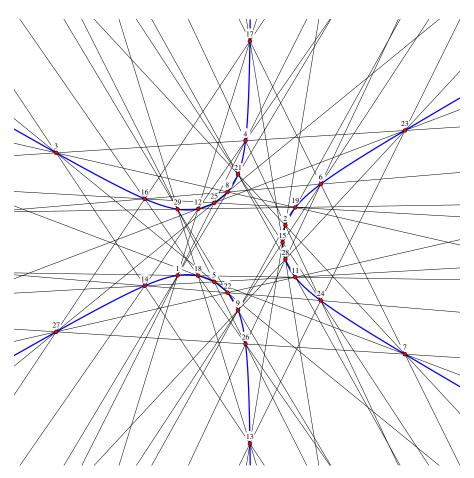

**3.2.**  $D_3$ -symmetric (9 $k_4$ , 12 $k_3$ ) configurations for  $k \equiv 1 \pmod{4}$ . Let  $k \geq 3$  be a positive integer with  $k \equiv 1 \pmod{4}$ . Furthermore, let  $n_k := 3k + 1$  and let  $m := n_k/2$ . Notice that since  $n_k \equiv 0 \pmod{4}$ , m is even.

As above, let  $S_0^* := S_0 \cup \{0\}$  and define the following sequence of triples  $\langle (a_i, b_i, c_i) : 0 \le i < n_k \rangle$  in  $S_0^* \times S_0^* \times S_0^*$ : Let

$$(a_0, b_0, c_0) := (0, n_k - 1, 1)$$
 and  $(a_1, b_1, c_1) := (2, n_k - 1, n_k - 1),$ 

and for all  $0 \le i < n_k - 2$  let

$$(a_{i+2}, b_{i+2}, c_{i+2}) := (a_i + 4, b_i - 2, c_i - 2) \pmod{n_k}.$$

**Figure 2.** An elliptic  $D_3$ -symmetric  $(27_4, 36_3)$  configuration.

Then, the sequence has the following properties:

- (a) For all  $0 \le i < n_k$ ,  $a_i + b_i + c_i \equiv 0 \pmod{n_k}$ ,  $a_i$  is even, and  $b_i$  and  $c_i$  are both odd.
- (b)  $(a_m, b_m, c_m) = (0, m-1, m+1).$
- (c) For all  $0 \le i < j < n_k$ ,  $\{a_i, b_i, c_i\} \ne \{a_j, b_j, c_j\}$ .
- (d) For all  $s \in \mathbb{Z}/n_k\mathbb{Z}$  we have  $-(a_s, b_s, c_s) = (a_{-s}, b_{-s}, c_{-s})$ .

Property (a) shows that every triple in the sequence is a proto-line in  $S_0^*$ . Property (c) shows that the sequence contains exactly  $n_k$  pairwise different proto-lines; let  $L^*$  be the set of these  $n_k$  proto-lines. Property (d) shows that a proto-line (u, v, w) is in  $L^*$  if and only if the proto-line -(u, v, w) is in  $L^*$ .

Every even number  $0 \le \ell < n_k$  appears in exactly 2 proto-lines in  $L^*$ , and every odd number  $0 < \ell < n_k$  appears in exactly 4 proto-lines in  $L^*$ . Now, we remove

the 2 proto-lines  $(0, n_k - 1, 1)$  and (0, m - 1, m + 1) from  $L^*$ , and introduce the 2 proto-lines  $(m, n_k - 1, m + 1)$  and (m, 1, m - 1) to  $L^*$ ; the resulting set of proto-lines is denoted  $L_0$ . Notice that  $(m, n_k - 1, m + 1) = -(m, 1, m - 1)$ , that the 2 proto-lines  $(m, n_k - 1, m + 1)$  and (m, 1, m - 1) are not in  $L^*$ , and that every proto-line in  $L_0$  is a proto-line in  $S_0$ . In  $L_0$ , every odd number  $0 < \ell < n_k$  appears in exactly 4 proto-lines in  $L_0$ , and every even number  $0 \le \ell < n_k$ , except m, appears in exactly 2 proto-lines in  $L_0$ , whereas m appears in exactly 4 proto-lines in  $L_0$ .

In order to complete the construction of a  $(9k_4, 12k_3)$  configuration, we consider the set  $T_k$  consisting of the  $n_k/2-1$  even numbers  $2, 4, \ldots, n_k-2$ . It remains to find k-1 proto-lines in  $S_0$  with points in  $T_k$ , where every number in  $T_k$  except m appears in exactly 2 proto-lines, whereas m does not appear in any proto-line.

For the construction of the remaining k-1 proto-lines with points in  $T_k$ , by trial and error we have found again a pattern, which is obtained in the following way: As above, we write just the proto-line with the greater number of •'s—having in mind that each proto-line (u, v, w) represents also the proto-line -(u, v, w). This way, we just have to find  $\frac{k-1}{2}$  proto-lines. The following diagram illustrates the 12 proto-lines for k=25 (i.e.,  $n_k=76$ ), given in two parts:

74	72	70	68	66	64	62	60	58	56	54	52	50	48	46	44	42	40	
2	4	6	8	10	12	14	16	18	20	22	24	26	28	30	32	34	36	38
	•									:							8	
i			•	<u>.</u>				: :		<u>.</u>				: : :				<u>.</u>
ļ	ļ		ļ		•					<u>.</u>		<u>.</u>			•			
	ļ		<u>.</u>				•			: }		: !		•		: :		
	ļ		ļ !	<u>.</u>					•	ļ !			•	!		<u>.</u> 		
	:		:	:	:					-	•			:		:		
-			}	:				•								: :		
		•				•			0									
	:	:	•	•	:			0		:		:	: :	:				
		•		•	;		0			}				{				
•					•	0				:		:						

First, notice that the proto-lines given in the diagram are different from the proto-lines constructed above. Furthermore, we see that each point, except the point 38, appears in exactly 2 proto-lines, whereas the point 38 does not appear in a proto-line. Notice that for k = 25, m = 38.

Now, we give a more formal construction of the remaining  $\frac{k-1}{2}$  proto-lines: the  $\frac{k-1}{4}$  proto-lines in the first part are

$$(4+4i, (m-2)-2i, (m-2)-2i)$$
 where  $0 \le i \le \frac{k-5}{4}$ .

In particular, for i=0 we obtain (4, m-2, m-2), and for  $i=\frac{k-5}{4}$  we obtain (k-1, k+1, k+1) (recall that  $m=\frac{3k+1}{2}$ ). Furthermore, the  $\frac{k-1}{4}$  proto-lines in the

second part are

$$(2+2i, (k-3)-4i, -(k-1)+2i)$$
 where  $0 \le i \le \frac{k-5}{4}$ .

In particular, for i = 0 we obtain (2, k - 3, -(k - 1)), and for  $i = \frac{k - 5}{4}$  we obtain  $\left(\frac{k - 1}{2}, 2, -\frac{k + 3}{2}\right)$ . Notice that the only number which does not appear in a proto-line is m, as required.

**Example 3.** We illustrate this construction for the parameter k = 5. This leads to an elliptic  $D_3$ -symmetric (45<sub>4</sub>, 60<sub>3</sub>) configuration. The construction gives the following:

- k = 5,  $n_k = 16$ , m = 8.
- The proto-lines in  $L^*$  are

- Remove (0, 15, 1) and (0, 7, 9) (i.e., the 2 triples which contain 0), and introduce (8, 15, 9) and (8, 1, 7). This gives us the 16 proto-lines of  $L_0$ .
- The diagram, which gives us additional  $\frac{k-1}{2} = 2$  lines consists of just 2 lines, 1 line in each part:

This gives us the k-1=4 lines (4, 6, 6), (12, 10, 10), (2, 2, 12), (14, 14, 4).

• Together with the 16 proto-lines in  $L_0$ , we have now 20 proto-lines which we extend to proper lines in S and rotate them.

Again, depending on how we extend the proto-lines to proper lines, and depending on the choice of the generator of  $\mathbb{Z}_{48}$ , we obtain different resulting configurations. One version is shown in Figure 3.

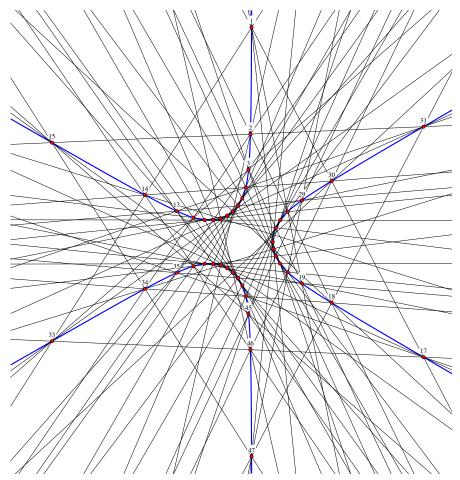

**3.3.**  $D_3$ -symmetric (9 $k_4$ , 12 $k_3$ ) configurations for k even. Let  $k \ge 2$  be an even integer and let  $n_k := 3k + 1$ . Notice that  $n_k$  is odd.

As above, let  $S_0^* := S_0 \cup \{0\}$  and define a sequence of triples  $\langle (a_i, b_i, c_i) : i \in \mathbb{Z} \rangle$  in  $S_0^* \times S_0^* \times S_0^*$  as follows: Let  $(a_0, b_0, c_0) := (0, 0, 0)$  and for all  $i \in \mathbb{Z}$  let

$$(a_{i+1}, b_{i+1}, c_{i+1}) := (a_i - 2, b_i + 1, c_i + 1).$$

Then, the sequence has the following properties:

(a) For all  $i \in \mathbb{Z}$ ,  $a_i + b_i + c_i \equiv 0 \pmod{n_k}$ , and  $b_i = c_i$ .

**Figure 3.** An elliptic  $D_3$ -symmetric (45<sub>4</sub>, 60<sub>3</sub>) configuration. For this figure we have chosen the generator 1 in  $\mathbb{Z}_{48}$ .

- (b) For  $t := \frac{3k}{2}$  we have  $(a_t, b_t, c_t) = (1, t, t)$ .
- (c) For all  $i \in \mathbb{Z}$ ,  $(a_{i+n_k}, b_{i+n_k}, c_{i+n_k}) = (a_i, b_i, c_i)$ , and for all  $0 < s < n_k$ ,  $\{a_{i+s}, b_{i+s}, c_{i+s}\} \neq \{a_i, b_i, c_i\}$ .
- (d) In  $\mathbb{Z}/n_k\mathbb{Z}$ , for  $t := \frac{3k}{2}$  and for all  $s \in \mathbb{Z}$  we have

$$-(a_{t+s}, b_s, c_s) = (a_{t-s+1}, b_{t-s+1}, c_{t-s+1}).$$

Property (a) shows that every triple in the sequence is a proto-line in  $S_0^*$ . Property (c) shows that the sequence contains exactly  $n_k$  pairwise different proto-lines, including the proto-line (0, 0, 0). Now, we remove the proto-line (0, 0, 0) and let  $L_0$  be the set of the remaining 3k proto-lines. Property (d) shows that a proto-line (u, v, w) is in  $L_0$  if and only if the proto-line -(u, v, w) is in  $L_0$ . Furthermore, notice that every number  $0 < \ell < n_k$  appears in exactly 3 proto-lines in  $L_0$ .

For the construction of the remaining k proto-lines in  $S_0$ , we will again visualize the argument. As above, we write just the proto-line with the greater number of  $\bullet$ 's—having in mind that each proto-line (u, v, w) represents also the proto-line -(u, v, w). This way, we just have to find  $\frac{k}{2}$  proto-lines. In order to clearly show the structure of the construction in the general proof, we omit the least point of a proto-line and write the number of the least point as an index to the other 2 points of the proto-line. For example, for k = 4 (i.e.,  $n_k = 13$ ) and the proto-line (1, 3, 9) we will write

12 11 10 9 8 7 1 2 3 4 5 6

instead of

1	12		11	:	10	:	9		8	7	:
:	1	:	2	:	3	:	4		5	6	:
Γ	•	:		1	•	:	_	:		:	7

This way, we can write different proto-lines in the same row without ambiguity. Later, we will omit the columns with points that appear as indices, which makes the tables less wide. For example, for k = 8 (i.e.,  $n_k = 25$ ) the following diagram represents the 3 proto-lines (1, 7, 17), (2, 9, 14), and (4, 6, 15):

:	24	23	22	21	20	19	18	17	16	15	14	13
:	1	2	3	4	5	6	7	8	9	10	11	12
		:	:	:	-	• /	<b>4</b> •1	01	•2	04	· 02	

We first consider the cases when k = 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, and then we consider the cases when  $k \ge 22$ , where we will consider the four cases  $k \equiv 0, 2, 4, 6 \pmod{8}$  separately.

The following diagrams show the  $\frac{k}{2}$  proto-lines for k = 2, 4, ..., 18, 20 (where we do not write the points which appear as indices):

5	4	:	10	9	8	7		15	14	13	12	11	10

k = 20

Notice that in the diagrams above, in the case when  $k \equiv 4, 6 \pmod{8}$ , there is always a single proto-line which contains just points from the second row. In fact, this will always be the case. Another feature of the diagrams above is that all the numbers  $1, \ldots, \frac{k}{2}$  appear as indices—this will also always be the case.

As mentioned, for  $k \ge 20$  we will consider the four cases  $k \equiv 0, 2, 4, 6 \pmod{8}$ separately. However, the structure of the proto-lines consisting only of even numbers is always the same. This structure is illustrated by the following diagram. In the diagram, u denotes the largest *even* number which is less than or equal to  $\frac{k}{2}$  (i.e., u is either  $\frac{k}{2}$  or  $\frac{k}{2} - 1$ ),  $M := \frac{k + u + 2}{2}$ , and  $N := \frac{k}{2} + 1$ :

 . N	N+1	 M-2	M - 1	М	M+1	M+2	 N+u-1	N + u	•••
			•2		°2				
	:	•4				°4			
 	:								
	$\bullet_{u-2}$						$\circ_{u-2}$		
 • <i>u</i>								$\circ_u$	

We will call these  $\frac{u}{2}$  proto-lines the *even block*. Notice that the structure of the even block already appears for k = 14, 16, 18.

In order to complete the proof of Theorem 4, we have to construct the remaining  $\frac{k}{2} - \frac{u}{2}$  proto-lines which consist only of *odd* numbers, the so-called *odd block*. The following four diagrams show the structure of these odd blocks for  $k \ge 22$ .

The structure of the odd block for  $k \ge 24$  and  $k \equiv 0 \pmod{8}$ . Let now  $k \equiv 0 \pmod{8}$  with  $k \ge 24$ . Then  $u = \frac{k}{2}$ ,  $M = \frac{3k}{4} + 1$ ,  $N = \frac{k}{2} + 1$ , and N + u = k + 1. Furthermore, let  $v := \frac{k}{2} - 1$  and  $w := \frac{k}{4} - 1$ ; then  $M + v = \frac{5k}{4}$ . Notice that v and w are both odd. The following diagram illustrates the construction of the odd block:

 М	 k+2	k+3	k+4	 $\frac{9k+8}{8}$	$\frac{9k+16}{8}$	 $\frac{5k-4}{4}$	$\frac{5k}{4}$	$\frac{5k+4}{4}$	$\frac{5k+8}{4}$	•••
 $\bullet_v$	 $\bullet_w$						$\circ_v$	$\circ_w$		
		$\bullet_{v-2}$						:		
			•v-4							
				$\bullet_{w+2}$						
								:		
					$\bullet_{w-2}$					
	:					•3		:	03	

 $\frac{11k - 8}{8}$	$\frac{11k}{8}$	$\frac{11k+8}{8}$	$\frac{11k+16}{8}$	•••	$\frac{3k-2}{2}$	$\frac{3k}{2}$

					$\circ_{v-4}$	
	· · · · · · · · · · · · · · · · · · ·		$\circ_{w+2}$			
	•1	٥1				
$\circ_{w-2}$						

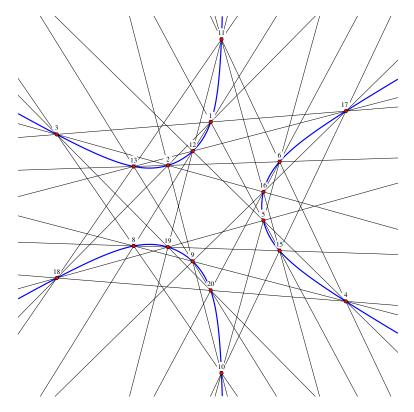

Notice that the odd block fits well with the even block: For example, the number M, which was missing in the even block, appears in the proto-line (v, M, -(M+v)) (recall that  $M+v=\frac{5k}{4}$ ). Furthermore, the number N+u+1=k+2, which is the least number which is bigger than the maximum of the numbers in the even block, appears in the proto-line  $(w, k+2, -(\frac{5k}{4}+1))$ . The other numbers of the odd block are covered by the proto-lines with least number  $v-2, v-4, \ldots, w+2, w-2, \ldots, 3, 1$ , where the proto-line

$$\left(1, \frac{11k}{8}, -\frac{11k+8}{8}\right)$$

covers the gap between the proto-lines

$$\left(w+2, \frac{9k+8}{8}, -\frac{11k+16}{8}\right)$$
 and  $\left(w-2, \frac{9k+16}{8}, -\frac{11k-8}{8}\right)$ .

The structure of the odd block for  $k \ge 26$  and  $k \equiv 2 \pmod{8}$ . For  $k \equiv 2 \pmod{8}$  with  $k \ge 26$ , let  $u = \frac{k}{2} - 1$ ,  $M = \frac{3k+2}{4}$ ,  $N = \frac{k}{2} + 1$ , and N + u = k. Furthermore,

**Figure 4.** An elliptic  $D_3$ -symmetric (18<sub>4</sub>, 24<sub>3</sub>) configuration.

let  $v := \frac{k}{2}$  and  $w := \frac{k-6}{4}$ ; then  $M + v = \frac{5k+2}{4}$ . The following diagram illustrates the construction of the odd block:

M k+1 k+2	8	8	4 : 4	
$\bullet_v$ $\bullet_w$ $\bullet_{v-2}$	$\bullet_{v-4}$ $\bullet_{w+2}$	$2 \bullet_{w-2}$	•3 •w

The structure of the odd block for  $k \ge 22$  and  $k \equiv 6 \pmod{8}$ . For  $k \equiv 6 \pmod{8}$  with  $k \ge 22$  let  $u = \frac{k}{2} - 1$ ,  $M = \frac{3k+2}{4}$ ,  $N = \frac{k}{2} + 1$ , and N + u = k. Furthermore, let  $v := \frac{k}{2}$  and  $w := \frac{k-6}{4}$ ; then  $M + v = \frac{5k+2}{4}$ . The following diagram illustrates the construction of the odd block:

Now consider the case k = 2 which yields an elliptic  $D_3$ -symmetric (18<sub>4</sub>, 24<sub>3</sub>) configuration. Figure 4 shows one realization of the resulting configurations.

# 4. On elliptic $(3r_4, 4r_3)$ configurations

In order to obtain an elliptic  $D_3$ -symmetric  $(9k_4, 12k_3)$  configuration, it was sufficient to construct 4k proto-lines in the 3k-element set  $S_0$ . Thus, if all the protolines we constructed were proper lines, then we would have an elliptic  $(3k_4, 4k_3)$  configuration — but this is in general not the case.

However, there is a simple algorithm which gives us elliptic  $(3r_4, 4r_3)$  configurations for infinitely many values of r. The algorithm is given in the proof of the following proposition.

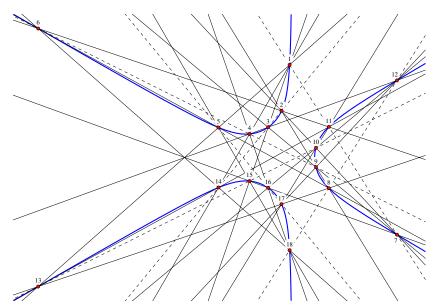

**Proposition 5.** For every prime p > 7, there is an elliptic  $((p-1)_3)$  configuration and for every prime p > 7 with 3r = p-1 (for some r), there is an elliptic  $(3r_4, 4r_3)$  configuration.

*Proof.* Let p > 7 be a prime, let  $\Gamma_0$  be an elliptic curve, and let P be a point on  $\Gamma_0$  of order p-1. Furthermore, let  $\mathbb{F}_p$  be the Galois field of order p. In the same way as above, we will construct the elliptic configurations in  $\mathbb{F}_p \setminus \{0\}$ .

First recall that for any prime p, the multiplicative group  $\mathbb{F}_p$  is cyclic, i.e., there exists a generator  $g \in \mathbb{F}_p$  such that  $\operatorname{ord}(g) = p - 1$ . Before we start the construction, let us prove the following claim.

**Claim.** If p > 7 is a prime, then the multiplicative group of  $\mathbb{F}_p$  has a generator g such that  $g \not\equiv -2$ ,  $\frac{p-1}{2}$  (mod p).

*Proof of Claim.* If  $\mathbb{F}_p$  has a generator g such that  $g \not\equiv -2$ ,  $\frac{p-1}{2}$  (mod p), then we are done. Now, assume that  $g = \frac{p-1}{2}$  is a generator. Then, for any n with 1 < n < p-1 and (n, p-1) = 1,  $g^n$  is also a generator. So, if we find two distinct n, m with 1 < n, m < p-1 and (n, p-1) = 1 = (m, p-1), then  $g, g^n$ , and  $g^m$  are pairwise distinct generators and we have found a generator which satisfies the conditions in the claim. It remains to show that for every prime p > 7 there are distinct n, m with 1 < n, m < p-1 such that (n, p-1) = 1 = (m, p-1), which is obviously the case.  $\square$ 

**Figure 5.** The solid and the dashed lines form an elliptic  $D_1$ -symmetric (18<sub>4</sub>, 24<sub>3</sub>) configuration derived from  $\mathbb{Z}/19\mathbb{Z}$ . The solid lines in the set  $L_0$  alone are an elliptic  $D_1$ -symmetric (18<sub>3</sub>) configuration.

Let now p > 7 be a prime and let g be a generator of the multiplicative group of  $\mathbb{F}_p$  with  $g \not\equiv -2$ ,  $\frac{p-1}{2}$  (mod p) and let

$$L_0 := \{ (g^n, g^{n+1}, -(g^n + g^{n+1})) : 0 \le n$$

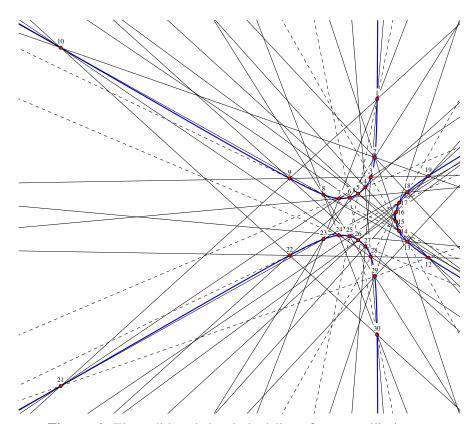

Then  $L_0$  is a set of p-1 lines in  $\mathbb{F}_p \setminus \{0\}$ . To see this, notice that by the properties of g, for all n we have  $g^n \neq g^{n+1}$  and that  $-(g^n + g^{n+1}) \in \{g^n, g^{n+1}\}$  would imply that  $g \equiv \frac{p-1}{2} \pmod{p}$  or  $g \equiv -2 \pmod{p}$ .

Now, with the p-1 lines in  $\mathbb{F}_p \setminus \{0\}$  and the point P on  $\Gamma_0$  of order p-1, we can easily construct a  $((p-1)_3)$  configuration with all its points on  $\Gamma_0$ .

Let us now assume that in addition to p > 7 we have that p - 1 = 3r for some  $r \ge 4$ , and let again g be a generator of the multiplicative group of  $\mathbb{F}_p$  with  $g \not\equiv -2$ ,  $\frac{p-1}{2}$  (mod p). Let  $x := g^r$  and let  $y := 1 + x + x^2$ . Then, since  $x^3 = 1$ , we have xy = y, which implies that  $x \equiv 0 \pmod{p}$  or  $1 + x + x^2 \equiv 0 \pmod{p}$ . Since the former is impossible (recall that g is a generator of the multiplicative group of  $\mathbb{F}_p$ ), we have that  $1 + x + x^2 \equiv 0 \pmod{p}$ , and since  $1, x, x^2$  are pairwise distinct, this implies that  $(1, x, x^2)$  is a line in  $\mathbb{F}_p$ . Consequently,

$$L_1 := \{a \cdot (1, x, x^2) : a \in \mathbb{F}_p \setminus \{0\}\}$$

is an *r*-element set of lines in  $\mathbb{F}_p$  which is disjoint from  $L_0$ . To see this, notice that no element of  $L_0$  is of the form  $a \cdot (1, x, x^2)$  for some  $a \in \mathbb{F}_p \setminus \{0\}$  and for all  $a, b \in \mathbb{F}_p \setminus \{0\}$ , if  $\{a, ax, ax^2\} \cap \{b, bx, bx^2\} \neq \emptyset$  then  $\{a, ax, ax^2\} = \{b, bx, bx^2\}$ .

**Figure 6.** The solid and the dashed lines form an elliptic  $D_1$ -symmetric (30<sub>4</sub>, 40<sub>3</sub>) configuration derived from  $\mathbb{Z}/31\mathbb{Z}$ , the solid lines alone are an elliptic  $D_1$ -symmetric (30<sub>3</sub>) configuration.

Thus,  $L_0 \cup L_1$  is a 4r-element set of lines in  $\mathbb{F}_p \setminus \{0\}$  and together with the point P on  $\Gamma_0$  of order p-1, we can easily construct a  $(3r_4, 4r_3)$  configuration with all its points on  $\Gamma_0$ .

**Example 4.** We illustrate the construction of the previous proof for the cases r = 6, i.e., we deal with the prime p = 3r + 1 = 19, where we have chosen the generator g = 3 in the multiplicative group of  $\mathbb{F}_{19}$ . The set  $L_0$  contains the lines

The set  $L_1$  adds the lines

$$(1, 7, 11), (2, 3, 14), (4, 6, 9), (5, 16, 17), (8, 12, 18), (10, 13, 15).$$

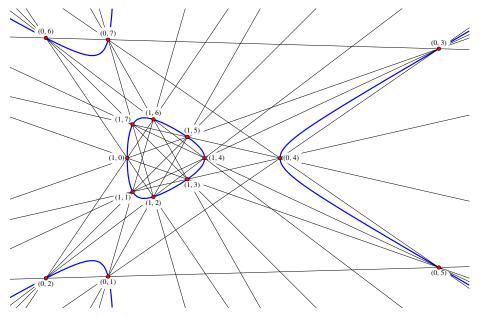

The resulting elliptic  $D_1$ -symmetric (18<sub>4</sub>, 24<sub>3</sub>) configuration is shown in Figure 5 (compare to Figure 4).

We also add the case r = 10, i.e., for the prime p = 3r + 1 = 31. Observe that since 30 = 3r is not a multiple of 9, the  $(30_4, 40_3)$  configuration cannot be realized by the methods from Section 3. We omit the list of points and refer directly to Figure 6.

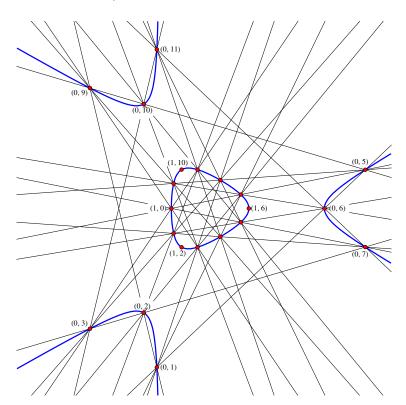

# 5. Elliptic configurations resulting from groups of the form $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/r\mathbb{Z}$

We conclude this paper by presenting some  $(3r_4, 4r_3)$  configurations which are derived from groups of the form  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/k\mathbb{Z}$  by similar methods. Here, the points are again constructed by using the Weierstrass  $\wp$ -function (see, e.g., [Coxeter 1950, p 440]). In Figure 7 we realize the group  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/8\mathbb{Z}$  on an elliptic curve consisting of two components. There are 15 real points and the point  $\mathscr O$  at infinity (0, 1, 0). Using all real points the result is an elliptic  $D_1$ -symmetric  $(15_4, 20_3)$  configuration. Notice that such a configuration cannot be constructed by the methods presented in Section 3 and Section 4.

Figure 8 shows an elliptic  $D_3$ -symmetric (18<sub>4</sub>, 24<sub>3</sub>) configuration derived from the group  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/12\mathbb{Z}$ . The group on the elliptic curve has 21 real points and 3 points at infinity. Using only 18 of the real points it is possible to realize a (18<sub>4</sub>, 24<sub>3</sub>) configuration sitting on two components of the elliptic curve. Recall that we had a (18<sub>4</sub>, 24<sub>3</sub>) configuration on a one component curve in Figure 4 and another one in Figure 5. It is clear that the three (18<sub>4</sub>, 24<sub>3</sub>) configurations in Figure 8, Figure 4 and

**Figure 7.** Elliptic  $D_1$ -symmetric  $(15_4, 20_3)$  configuration derived from  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/8\mathbb{Z}$ 

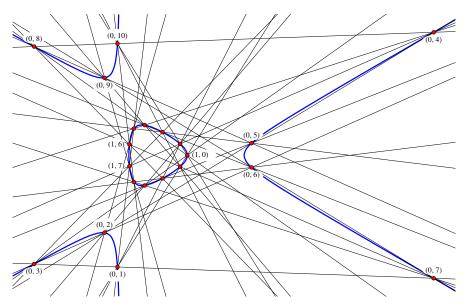

**Figure 8.** Elliptic  $D_3$ -symmetric (18<sub>4</sub>, 24<sub>3</sub>) configuration derived from  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/12\mathbb{Z}$ .

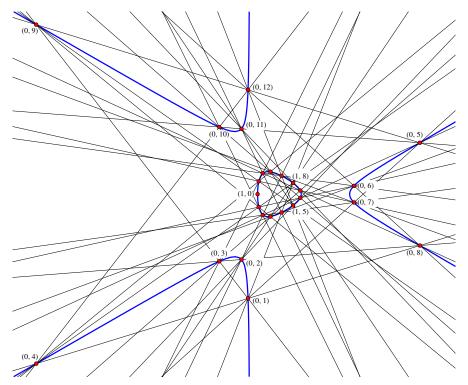

Figure 5 are not projectively isomorphic, since the respective cubic curves are not projectively isomorphic. However, the configurations could still be combinatorially isomorphic. But the Menger graphs (see [Coxeter 1949, p. 28]) of the three configurations turn out to be nonisomorphic: the ranks of the corresponding adjacency matrices are different. In general the question may be more delicate to settle as one might have to look at the Levi graph (see [Levi 1942, p. 5]) of the configurations since the Menger graphs of nonisomorphic configurations may be isomorphic (see [Coxeter 1950], [Grünbaum 2009, Section 1.4] and the open questions in Section 6).

For Figure 9 we started with the group  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/11\mathbb{Z}$  with 21 real points and 1 point at inifinity. Here, an elliptic  $D_1$ -symmetric (21<sub>4</sub>, 28<sub>3</sub>) configuration results. Such a configuration cannot be constructed by the methods presented in Sections 3 and 4.

Our last example starts with the group  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/13\mathbb{Z}$  with 25 real points on the curve and 1 point at infinity. Omitting the real point corresponding to the group element (1,0) of order 2, we have 24 real points which carry an elliptic  $D_1$ -symmetric  $(24_4,32_3)$  configuration, as shown in Figure 10. Such a configuration cannot be constructed by the methods presented in Sections 3 and 4.

**Figure 9.** Elliptic  $D_1$ -symmetric  $(21_4, 28_3)$  configuration derived from  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/11\mathbb{Z}$ .

**Figure 10.** Elliptic  $D_1$ -symmetric (24<sub>4</sub>, 32<sub>3</sub>) configuration derived from  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/13\mathbb{Z}$ 

#### 6. Open problems

As always, with every solved problem, new questions arise. For example:

- (1) For certain values of r, several of the presented methods can be used to produce a  $(3r_4, 4r_3)$  configuration. Even within the methods there is some freedom (e.g., the choice of the generator of the respective group, or in the construction of the proto-lines). Which of these configurations are combinatorially or projectively isomorphic?
- (2) Is it possible to generalize the methods we used for the construction of configurations starting from groups of the form  $\mathbb{Z}/k\mathbb{Z}$  to groups of the form  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/k\mathbb{Z}$  to find other  $(3r_4, 4r_3)$  configurations?
- (3) Can the configurations that we constructed also be geometrically realized without the points lying on cubic curves? Are there realizations with other symmetry types?

## Acknowledgement

We would like to thank the two referees for their careful reading and their numerous comments that helped to improve this article.
