# PROJECTIVE MODULES OVER SIMPLE REGULAR RINGS

JIRO KADO

(Received July 7, 1978) (Revised October 30, 1978)

Recently K.R. Goodearl and D. Handelman [6] have studied simple regular rings from the point of view of dimension-like functions. They have shown that there exists a unique dimension function on the lattice of principal right ideals of a simple, regular and directly finite ring satisfying the comparability axiom. In this note we study some structures of projective modules over such a ring by making use of the dimension function.

In the section 1 we show that if there exists a dimension function on the lattice of principal right ideals of a regular ring, then this can be extended to a function on the set of all projective modules.

In the section 2 we investigate some structures of projective modules over a simple, regular and directly finite ring satisfying the comparability axiom and show that a directly finite projective module is isomorphic to a direct sum of a finitely generated free module and a projective right ideal, and a directly infinite projective module is a free module.

In the final section directly finite, regular and right self-injective rings are investigated. We show that this ring is a finite direct product of simple rings if and only if any non-singular directly finite injective right module is a finitely generated module.

Throughout this paper a ring R is an associative ring with identity and modules are unitary right R-modules.

#### 1. Dimension functions

For any (Von Neumann) regular ring R, let L(R) be the lattice of principal right ideals and P(R) (FP(R)) the set of all projective (finitely generated projective) R-modules. We denote by  $M \leq N$  the fact that M is isomorphic to a submodule of N for two modules M, N. In particular if R is regular, then  $A \leq P$  for A in FP(R) and P in P(R) if and only if A is isomorphic to a direct summand of P [8, Lemma 4].

DEFINITION [6, p. 807]. A dimension function D on L(R) is a function from L(R) into non-negative real numbers satisfying the following conditions;

- (1) D(J)=0 if and only if J=0
- (2) D(R)=1
- (3) if  $J \lesssim K$ , then  $D(J) \leq D(K)$
- (4) if  $J \oplus K \in L(R)$ , then  $D(J \oplus K) = D(J) + D(K)$ .
- I. Halperin [7] proved that if a dimension function D exists on L(R), then D can be uniquely extended to a function on FP(R). We shall show that this function D can be moreover extended to a function on P(R) by making use of the following lemma.

**Lemma 1.1** [10]. For any projective module P over a regular ring, P is isomorphic to a direct sum of principal right ideals and any two direct sum decompositions of P have an isomorphic refinement.

Let P be in P(R). From now on, by  $P=\oplus_{J\in\mathfrak{M}}J$  we denote the fact that there exists a set  $\mathfrak{M}$  of independent non-zero submodules isomorphic to some principal right ideal and P is a direct sum of the members of  $\mathfrak{M}$ . We put  $D^*(P)=\sup\{\sum_{J\in\mathfrak{M}'}D(J);$  any finite subset  $\mathfrak{M}'$  of  $\mathfrak{M}\}$  for any P in P(R) and any decomposition  $P=\oplus_{J\in\mathfrak{M}}J$ . If the above supremum is not convergent, we put  $D^*(P)=\infty$ . Now we shall prove that  $D^*(P)$  does not depend on the decomposition of P. Let  $P=\bigoplus_{K\in\mathfrak{N}}K$  be another decomposition. It is sufficient to prove that two numbers a, b defined by  $\mathfrak{M}$  and  $\mathfrak{N}$  coincide when  $\mathfrak{N}$  is a refinement of  $\mathfrak{M}$ . For any J in  $\mathfrak{M}$ , there exists a finite subset  $\mathfrak{N}'$  of  $\mathfrak{N}$  such that  $J=\bigoplus_{K\in\mathfrak{N}'}K$ . Hence we have  $a\leq b$ . Conversely for any finite subset  $\mathfrak{N}'$  of  $\mathfrak{N}$  and any K in  $\mathfrak{N}'$ , there exists some J in  $\mathfrak{M}$  such that K is a direct summand of J. Therefore there exists a finite subset  $\mathfrak{M}'$  of  $\mathfrak{M}$  such that  $\sum_{K\in\mathfrak{N}'}D(K)\leq\sum_{J\in\mathfrak{M}'}D(J)$  and so we have  $b\leq a$ .

Now  $D^*$  is a function from P(R) into non-negative real numbers or  $\infty$ , and from the definition and by Lemma 1.1, we can easily prove the following properties;

- (1) if  $P \lesssim Q$  in P(R), then  $D^*(P) \leq D^*(Q)$
- (2) if  $P \oplus Q \in P(R)$ , then  $D^*(P \oplus Q) = D^*(P) + D^*(Q)$ .

## 2. Projective modules

First we recall some definitions and some results in [6].

DEFINITION. A ring R is directly finite if xy=1 implies yx=1 for x, y in R. A module M is directly finite if  $End_R(M)$  is directly finite. A ring R (a module M) is directly infinite if it is not directly finite. It is easily seen that a module M is directly finite if and only if M is not isomorphic to a proper direct summand of itself. A regular ring R satisfies the comparability axiom if we have either  $J \lesssim K$  or  $K \lesssim J$  for all J, K in L(R). For a cardinal number  $\alpha$  and

a module M,  $\alpha M$  denotes a direct sum of  $\alpha$  copies of M.

Note. Throughout this section R is a simple, regular and directly finite ring satisfying the comparability axiom. In this case, any finitely generated projective R-module is directly finite by [6, Corollary 3.10].

EXAMPLE [6, pp. 815, 831 and 832]. Let F be a field and  $R_n$  the full matrix ring of degree  $2^n$  over F. Let  $f_n: R_n \to R_{n+1}$  be a diagonal homomorphism, i.e.,  $x \to \binom{50}{0x}$ , and let R be a direct limit of  $\{R_n, f_n\}$ . This ring R is a simple, regular and directly finite ring which satisfies the comparability axiom and which is not artinian. Further R is neither left nor right self-injective.

**Lemma 2.1** [6, Theorem 3.13 and Proposition 3.14]. Let J be in L(R). We put  $D(J)=\sup\{mn^{-1}; m\geq 0, n>0, mR\leq nJ\}$ . Then D is a unique dimension function on L(R). Further, for all J, K in L(R), we have  $J\leq K$  if and only if  $D(J)\leq D(K)$ .

From now on, let  $D^*$  be the extension of the dimension function D as in the section 1. We consider projective modules over R from the point of view of  $D^*$ .

**Lemma 2.2** Let A, B in FP(R).  $A \leq B$  if and only if  $D^*(A) \leq D^*(B)$ . In particular,  $A \cong B$  if and only if  $D^*(A) = D^*(B)$ .

Proof. We have  $A \lesssim B$  or  $B \lesssim A$  by [6, Lemma 3.7]. Then the proof of the first property is easy. If  $D^*(A) = D^*(B)$ , then  $A \lesssim B$  and  $B \lesssim A$ . Hence A is isomorphic to a direct summand of itself. Then  $A \cong B$ , because A is directly finite.

The next is a key lemma for Theorem 2.4.

**Lemma 2.3.** For P in P(R) and A in FP(R),  $P \leq A$  if and only if  $D^*(P) \leq D^*(A)$ .

Proof. By the definition, "only if" part is trivial. We assume  $D^*(P) \leq D^*(A)$  and  $P = \bigoplus_{J \in \mathfrak{M}} J$ . First we know  $\mathfrak{M}$  is a countable set, because for each positive integer n, the set  $\mathfrak{M}_n = \{J; D(J) > n^{-1}\}$  is a finite set and  $\mathfrak{M} = \bigcup_n \mathfrak{M}_n$ . Now put  $\mathfrak{M} = \{J_n; n = 1, 2, \cdots\}$  and  $P_n = \bigoplus_1^n J_i$ , then we have  $P = \bigcup_n P_n$ . For each n, we can choose a monomorphism  $f_n \colon P_n \to A$  by Lemma 2.2, because  $D^*(P_n) \leq D^*(A)$ . If we construct monomorphism  $g_n \colon P_n \to A$  for each n such that  $g_{n+1}$  is an extension of  $g_n$ , then we have  $P \lesssim A$ . Put  $g_1 = f_1$  and assume we have  $g_k$  for all  $k \leq n$ . We have decompositions  $A = g_n(P_n) \oplus Q_n = f_{n+1}(P_n) \oplus f_{n+1}(J_{n+1}) \oplus Q_{n+1}$  for some submodules  $Q_n, Q_{n+1}$ , because homomorphism  $g_n, f_{n+1}$  split. Then we have  $Q_n \cong f_{n+1}(J_{n+1}) \oplus Q_{n+1}$  by [6, Theorem 3.9] and so we choose a monomorphism  $h \colon f_{n+1}(J_{n+1}) \to Q_n$ . Consequently  $g_{n+1} = g_n \oplus h f_{n+1} \colon P_{n+1} \to A$  is an extension of  $g_n$ .

We shall determine the structures of projective modules over a simple, regular and directly finite ring satisfying the comparability axiom.

**Theorem 2.4.** Let R be a simple, regular and directly finite ring satisfying the comparability axiom. For a projective R-module P, the following conditions are equivalent.

- (1) P is directly finite.
- (2)  $D^*(P) < \infty$
- (3) P has a decomposition  $P \cong nR \oplus J$  for some integer  $n \ge 0$  and some right ideal J.
  - (4)  $P \lesssim tR$  for some integer t > 0.
- Proof. (1) $\Rightarrow$ (2). We assume  $D^*(P)=\infty$ . Put  $P=\bigoplus_{J\in\mathfrak{M}}J$ , then there exists a sequence of finite subsets  $\mathfrak{M}_i$  ( $i=1,2,\cdots$ ) of  $\mathfrak{M}$  such that  $\mathfrak{M}_i\cap\mathfrak{M}_j=\phi$  if  $i\neq j$  and  $D^*(\bigoplus_{J\in\mathfrak{M}_i}J)\geq 1$  for each i. Put  $P_i=\bigoplus_{J\in\mathfrak{M}_i}J$ , then we have  $R\lesssim P_i$  by Lemma 2.2 and so we have  $P_i=R_i\oplus Q_i$ , where  $R_i\cong R$ .  $F=\bigoplus_1^\infty R_i$  is a direct summand of P and  $2F\cong F$ . This contradicts that every direct summand of P is also directly finite.
- (2) $\Rightarrow$ (3). We choose non-negative integer n such that  $n < D^*(P) \le n+1$ . If n=0, then we have  $P \le R$  by Lemma 2.3. If n is positive, the first inequality implies that  $nR \le P$  from the definition of  $D^*$  and by Lemma 2.2. Then we have  $P=P_1 \oplus P_2$ , where  $P_1 \cong nR$ .  $D^*(P_2)=D^*(P)-D^*(P_1) \le 1$  implies  $P_2 \le R$  by Lemma 2.3.
  - $(3) \Rightarrow (4)$  It is trivial.
- (4) $\Rightarrow$ (1) If P is directly infinite, then there exists a set  $\{P_i\}_1^{\infty}$  of independent non-zero cyclic submodules of P such that  $P_i \cong P_j$  for all i, j. Then  $D^*(\bigoplus_{i=1}^{\infty} P_i) = \infty$ . This contradicts  $D^*(P) \leq t$ .

REMARK. A right ideal of R is projective if and only if it is countably generated. Further any right ideal has a projective submodule as an essential one [4, Lemmas 12 and 13].

The next three results follow to the advice of K. Oshiro.

**Lemma 2.5.** Let P and Q be countably generated but not finitely generated projective R-modules. If  $D^*(P)=D^*(Q)$ , then  $P \cong Q$ .

Proof. Since P and Q are not finitely generated, we put  $P = \bigoplus_{i=1}^{\infty} P_n$  and  $Q = \bigoplus_{i=1}^{\infty} Q_m$ , where each  $P_n$  and  $Q_m$  are isomorphic to some non-zero members of L(R). We prove that there exist two increasing sequences  $1 = n(1) < n(2) < \cdots$ ,  $1 \le m(1) < m(2) < \cdots$ , of positive integers and two sets  $\{A_i\}_{i=1}^{\infty}$ ,  $\{B_i\}_{i=1}^{\infty}$  of independent non-zero submodules of P satisfying, for each i

- $(1) \quad \bigoplus_{n(i)+1}^{n(i+1)} P_i = B_i \bigoplus A_{i+1}$
- $(2) \quad \bigoplus_{m(i-1)+1}^{m(i)} Q_i \cong A_i \oplus B_i$

where  $A_1 = P_1$  and m(0) = 0.

First we choose integers  $1 \le m(1)$ , 1 < n(2) such that  $D^*(P_1) < D^*(\bigoplus_{t=1}^{m(1)} Q_t) \le n(2)$  $D^*(\bigoplus_{i=1}^{n(2)} P_i)$ . Then, by Lemma 2.2, we have  $P_1 \oplus X \cong \bigoplus_{i=1}^{m(1)} Q_i$  and  $\bigoplus_{i=1}^{m(1)} Q_i \oplus Y_i$  $\cong \bigoplus_{i=1}^{n(2)} P_{i}$ , for some modules X, Y. Then we have  $X \oplus Y \cong \bigoplus_{i=1}^{n(2)} P$  by [6, Theorem 3.9]. Put n(1)=1,  $A_1=P_1$  and  $B_1\oplus A_2=\oplus_2^{n(2)}P_i$ , where  $B_1\cong X$  and  $A_2 \cong Y$ . Next we assume that there exist two increasing sequences,  $n(1) < \cdots$  $\langle n(k+1), m(1) \langle \cdots \langle m(k) \text{ and two sets } \{A_i\}_{i=1}^{k+1}, \{B_i\}_{i=1}^{k} \text{ of independent non-zero} \}$ submodules of P satisfying the properties (1) and (2). Since  $\bigoplus_{i=1}^{k} (A_i \oplus B_i) \cong$  $\bigoplus_{i=1}^{m(k)} Q_i$  and  $D^*(P) = D^*(Q)$ , then  $D^*(A_{k+1} \oplus (\bigoplus_{i=1}^{\infty} P_i)) = D^*(\bigoplus_{i=1}^{\infty} Q_i)$ . We can take positive integers m(k+1), n(k+2) such that m(k) < m(k+1), n(k) < n(k+2)and  $D^*(A_{k+1}) < D^*(\bigoplus_{m(k)+1}^{m(k+1)} Q_t) \le D^*(A_{k+1} \bigoplus (\bigoplus_{n(k+1)+1}^{n(k+2)} P_i))$ . Then, again by Lemma 2.2, we obtain  $A_{k+1} \oplus X' \cong \bigoplus_{m(k)+1}^{m(k+1)} Q_t$  and  $\bigoplus_{m(k)+1}^{m(k+1)} Q_t \oplus Y' \cong A_{k+1} \oplus A_{k+1}$  $(\bigoplus_{n(k+1)+1}^{n(k+2)} P_i)$ , for some modules X', Y'. Since  $A_{k+1} \oplus X' \oplus Y' \cong A_{k+1} \oplus A_{k+1} \oplus$  $(\bigoplus_{n(k+1)+1}^{n(k+2)} P_i)$ , then we have a decomposition  $\bigoplus_{n(k+1)+1}^{n(k+2)} P_i = B_{k+1} \bigoplus A_{k+2}$ , where  $B_{k+1} \cong X'$  and  $A_{k+2} \cong Y'$ , by [6, Theorem 3.9]. By the above procedure, we can construct independent non-zero submodules  $A_1, B_1, A_2, B_2, \cdots$  which satisfy the properties (1) and (2). Since each  $P_n$  is contained in  $B_i \oplus A_{i+1}$  for some i, then  $P = \bigoplus_{i=1}^{\infty} (A_i \oplus B_i)$ . On the other hand we have  $Q = \bigoplus_{i=1}^{\infty} (\bigoplus_{m(i-1)+1}^{m(i)} Q_i)$ . Therefore we conclude that  $P \cong Q$ .

REMARK. The result obtained by applying Lemma 2.5 for P, Q in  $P^*(R)$  means that the Grothendieck group generated by the isomorphism classes of directly finite projective R-modules is isomorphic to some subgroup of the additive group of R. (Cf. [2, Corollaries. 10.14 and 10.16]).

**Theorem 2.6.** Let R be a simple, regular and directly finite ring satisfying the comparability axiom. Any directly infinite projective R-modules is a free R-module.

Proof. By Theorem 2.4 and Lemma 2.5, we already see that every directly infinite, countably generated projective R-module is isomorphic to  $\aleph_0 R$ . Thus we shall show that every directly infinite projective R-module can be expressed as a direct sum of directly infinite, countably generated submodules. Let  $P = \bigoplus_{\alpha \in I} P_{\alpha}$  be a directly infinite projective R-module, where each  $P_{\alpha}$  is isomorphic to some non-zero I in I(R). Let  $\mathfrak B$  be the set of all countably infinite subsets of I. We consider the family consisting of all subsets  $\mathfrak F$  of  $\mathfrak B$  satisfying the following properties;

- (1) each members of  $\mathfrak{F}$  is pairwise disjoint
- (2)  $D^*(\bigoplus_{\alpha \in K} P_{\alpha}) = \infty$  for each K in  $\mathfrak{F}$ .

Since this family is a inductively ordered set using the inclusion relation, there exists a maximal member  $\mathfrak{F}$  by Zorn's Lemma. Put  $I^*=\bigcup_{K\in\mathfrak{F}}K$ . If  $I^*=I$ , then our proof is complete. Next we consider the case that  $I^* \neq I$ . First we shall show that  $D^*(\bigoplus_{\alpha \in I^{**}P_\alpha}) < \infty$ , where  $I^{**}$  is the complement of  $I^*$ . Other-

wise we can take a countably infinite subset I' of  $I^{**}$  such that  $D^*(\bigoplus_{\alpha \in I'} P_{\alpha}) = \infty$ . Then the set  $\mathfrak{F} \cup \{I'\}$  is strictly greater than  $\mathfrak{F}$ . This is a contradiction. By the proof of Lemma 2.3, we see that  $I^{**}$  is a countable set. Choose one member K' of  $\mathfrak{F}$ , and put  $\mathfrak{F}' = \mathfrak{F} - \{K'\}$ , and  $K'' = K' \cup I^{**}$ . Then K'' is a countably infinite set and  $D^*(\bigoplus_{\alpha \in K''} P_{\alpha}) = \infty$ . The decomposition  $P = (\bigoplus_{K \in \mathfrak{F}'} (\bigoplus_{\alpha \in K} P_{\alpha})) \oplus (\bigoplus_{\alpha \in K''} P_{\alpha})$  is a desired one.

DEFINITION [5, p. 174]. Let A be a module. If A=0, define  $\mu(A)=0$ . If  $A \neq 0$ , define  $\mu(A)$  to be the smallest infinite cardinal number  $\alpha$  such that  $\alpha A \lesssim A$ .

**Proposition 2.7.** Let P and S be projective modules which are not finitely generated. If  $P \lesssim S$  and  $S \lesssim P$ , then  $P \cong S$ .

Proof. Since  $D^*(P)=D^*(S)$  by the definition of  $D^*$ , then they are both directly finite or both directly infinite by Theorem 2.4. If P and S are directly finite, then they are countably generated by the proof of Lemma 2.3. Thus we have  $P \cong S$  by Lemma 2.5. If P and S are directly infinite, then  $P \cong \alpha R$  and S  $\cong \beta R$  for some infinite cardinal numbers  $\alpha$ ,  $\beta$  by Theorem 2.6. We can assume  $\alpha \leq \beta$ . Let Q be the maximal ring of quotients of R and we use the notation E(A) to stand for an injective hull of a module A. Since  $P \leq S$  and  $S \leq P$ , then  $E(P) \cong E(S)$  by [1, Corollary]. On the other hand,  $E(P) \cong E(\alpha Q)$  and E(S) $\cong E(\beta Q)$  and also Q is a prime ring because it satisfies the comparability. Therefore, by [5, Theorem 6.32],  $\max\{\alpha', \mu(Q)\} = \mu(E(P)) = \mu(E(S)) = \max\{\beta', \mu(Q)\},\$ where  $\alpha'$  and  $\beta'$  are the successores of  $\alpha$  and  $\beta$ . Thus, if  $\alpha < \beta$ , then it must hold that  $(\aleph_1 \leq \alpha) \leq \mu(Q)$ . Since  $\aleph_1 < \mu(Q)$ ,  $\aleph_1 Q \leq Q$ . Therefore let  $\{A_\tau\}_{\tau \in I}$ be a independent set of principal right ideals of Q such that  $A_{\tau}{\cong}Q$  for each  $\tau$  in I and the cardinality of I is  $\aleph_1$ . Then  $\{A_\tau \cap R\}_{\tau \in I}$  is a independent set of nonzero right ideals of R. This contradicts the fact that there is no uncountable direct sum of non-zero right ideals of R. Consequently we must have  $\alpha = \beta$  and hence  $P \cong S$ .

### 3. Directly finite, regular and right self-injective ring

**Lemma 3.1** [3, Lemma 5' and 6, Proposition 1.4]. A prime, directly finite, regular and right self-injective ring is a simple ring satisfying the comparability axiom.

**Proposition 3.2.** Let R be a directly finite, regular and right self-injective ring. Then R is a finite direct product of simple rings if and only if any non-singular directly finite injective R-module is finitely generated.

Proof. First we shall prove that "only if" part. There exists a set  $\{e_i\}_1^n$  of orthogonal central idempotents such that  $\sum_{i=1}^n e_i = 1$  and each  $e_i R$  is a simple

ring. Let M be a non-singular directly finite injective R-module. There exists a projective R-module P such that P is an essential submodule of M, because any non-singular finitely generated R-module is a projective and injective module (cf. [9, Theorem 2.7]). M is directly finite, and so P is also directly finite. Put  $P_i = Pe_i$  for each i, then each  $P_i$  is also a directly finite projective module as an  $e_iR$ -module. Therefore there exists a positive integer t such that  $P_i \lesssim t(e_iR)$ for all i by Lemma 3.1 and Theorem 2.4. Thus  $P \lesssim tR$ , because  $P = \bigoplus_{i=1}^{n} P_{i}$ . This monomorphism can be extended to be monomorphism from M into tR. Then M is isomorphic to a direct summand of tR. Conversely we assume that R can be decomposed into no finite direct product of prime rings. Then R itself is not prime. Hence there exist non-zero two-sided ideals A, B such that AB=0. Let A', B' be the injective hull of A, B in R, then they are also two-sided ideals and generated by central idempotents by [3, Lemma 1]. Since R is semi-prime,  $A \cap B = 0$ . Then  $A' \cap B' = 0$ . Hence there exist orthogonal central idempotents  $\{e_i\}_1^3$  such that  $\sum_{i=1}^3 e_i = 1$ . By the assumption, at least one of  $e_i R$ , say  $e_j R$ , is not prime. Use the same argument for the ring  $e_j R$ , then there exists another set  $\{e_i'\}_{i=1}^{5}$  of orthogonal central idempotents of R such that  $\sum_{i=1}^{5} e_{i}' = 1$ . Repeating these procedures, we obtain a countably infinite set  $\{e_{n}\}_{1}^{\infty}$ of orthogonal non-zero central idempotents. If  $\bigoplus_{1}^{\infty} e_{n}R$  is not essential in  $R_{R}$ , we choose some central idempotent f which generates the injective hull of  $\bigoplus_{1}^{\infty} e_n R$ and we consider  $\{e_n, 1-f\}_1^{\infty}$ . Therefore we may assume that  $\bigoplus_{i=1}^{\infty} e_i R$  is essential in  $R_R$ . Since  $R_R$  is injective and  $\bigoplus_{1}^{\infty} e_n R$  is a two-sided ideal,  $R \cong End_R(\bigoplus_{1}^{\infty} e_n R)$ .  $End_R(\bigoplus_{1}^{\infty}e_nR) \cong \prod_{n}End_R(e_nR) \cong \prod_{n}e_nR$ , because  $Hom_R(e_nR, e_mR) = 0$  for  $n \neq m$  and each  $e_n$  is a central idempotent. Consequently  $R \cong \prod_n e_n R$  by the mapping:  $r \to \infty$  $(e_n r)$ . We put  $M_n = n(e_n R)$  for each n and we consider the R-module  $M = \prod_n M_n$ . This is obviously a non-singular injective R-module. We also know that it is directly finite, because  $End_R(M) \cong \prod_n End_R(M_n)$  and  $End_R(M_n)$  is directly finite for all n. By the assumption, there exists a positive integer t such that  $M \le tR$ . Now we choose an integer m which is larger than t. That  $M_m \lesssim tR \cong \prod_n t(e_n R)$ implies that  $M_m \lesssim t(e_m R)$ , because  $Hom_R(M_m, t(e_n R)) = 0$  for all  $n \neq m$ . This contradicts that  $M_m$  is directly finite. Hence R is a finite direct product of prime rings. Prime directly finite regular right self-injective rings are simple by Lemma 3.1, and so we have proved.
